Data Sheet Compendium

1983–84

**Datapharm Publications Limited
12 Whitehall, London SW1A 2DY**

Responsibility for Data Sheets

The data sheets in this Compendium are prepared independently by each participating company and each proof is checked and the text confirmed as correct by the participant concerned. Neither Datapharm Publications Limited nor the Association of the British Pharmaceutical Industry (ABPI) give any guarantee whatsoever as to the accuracy of the information contained in the data sheets and accept no liability whatsoever in respect of any loss, damage or expense arising from any such information or for any error or omission in the data sheets and in particular (but without prejudice to the generality of the foregoing) shall not be liable for any consequential damages or expenses or any loss of profit or any liability to third parties incurred by anyone relying on the information contained in the data sheets appearing in this Compendium.

Copyright © 1983

Copyright in the material included in this Compendium is reserved by the individual companies and organisations which have contributed it.

ISBN 0 907102 00 X

ISSN 0306-9133

It is anticipated that the next edition of
the ABPI Data Sheet Compendium will be published in April 1984

Published by Datapharm Publications Limited

by William Clowes (Beccles) Limited, Beccles and London

The Compendium

Physiological Values

Weights and Heights

Obstetric Table

For the convenience of users of the Compendium, this edition includes physiological values for certain body fluids, tables of 'desirable' weights for men and women and an obstetric table.

This information can be found in the tinted section at the back of the Compendium.

Indexes

An alphabetical index of products, an index of non-proprietary names and a directory of participating companies (together with their telephone numbers) are provided in the tinted section at the back of the Compendium.

A list is also provided of products which are the subject of data sheets in this edition of the Compendium but which were not included in the 1981-82 edition.

Data sheets

Data sheets are supplied to practitioners in order to comply with the requirements of the Medicines Act 1968.

They are prepared by the individual companies concerned and, in consequence, vary somewhat in style. All follow, however, the requirements which are laid down by 'The Medicines (Data Sheet) Regulations 1972'.

Participation in the Compendium is open to all companies manufacturing medicinal products intended for use under medical supervision.

Further information

The regulations which relate to data sheets restrict the scope of the material which may be given under the heading 'Further information' and require insertion of the word 'Nil' in any data sheet where there is no entry under that heading. Manufacturers are, of course, none the less always willing to provide additional information on their products upon request.

Enquiries should be directed to the companies concerned.

Legal category

The following abbreviations are used under the heading 'Legal category' in entries in the Compendium.

GSL A preparation which is included in the General Sale List.

P A pharmacy sale medicine which can be sold only from a retail pharmacy.

POM A prescription only medicine.

MDA A preparation containing a substance included in Schedule 2 to the Misuse of Drugs Regulations 1973 (Misuse of Drugs Act 1971).

Doctors are reminded that the Misuse of Drugs Regulations 1973 lay down special requirements relating to the writing of prescriptions for products coming within Schedule 2.

Date of preparation

The data sheets included in this Compendium were prepared or reviewed during the third quarter of 1982 and the compendium itself was published in January 1983.

Revised data sheets

Individual participating companies may issue loose leaf data sheets which supersede those included in this Compendium.

It is advisable to retain any such revised data sheets which are received and to appropriately mark the corresponding entries in the Compendium.

Trade marks

An asterisk by the name of a product indicates that the name is a trade mark. The company symbols which appear in certain participants' sections are also trade marks.

Code of Practice for the Pharmaceutical Industry

Revised Fifth edition (April 1982)

For many years members of the Association of the British Pharmaceutical Industry have voluntarily agreed to observe the principles set out in a *Code of Practice for the Pharmaceutical Industry*; a Code which regulates the standards of conduct to be followed in the marketing of medicines intended for use under medical supervision.

The Code was first published in 1958 and has been regularly revised to take account of changes in marketing practices. A fifth edition was introduced in 1978 and revised in 1982; publication on each occasion following consultation with the British Medical Association and the Department of Health and Social Security. The Code embodies the basic principles and procedures which the pharmaceutical industry believes to be essential for the conduct of its marketing activities and for the maintenance of standards which are in the interests alike of the public, the medical and allied professions and the industry.

On occasion, the criticism has been made that members of the medical profession were not aware of the provisions of the Code and, consequently, that the Code had been less effective than might otherwise have been the case. To ensure that these provisions become better known, the revised fifth edition of the Code has been reproduced in its entirety below.

Those who feel that the promotion of a medical speciality product has fallen below the standards which are required by the Code may write, if they so wish, to the Secretary, Code of Practice Committee, The Association of the British Pharmaceutical Industry, 12 Whitehall, London SW1A 2DY, and ask that the matter be investigated.

INTRODUCTION

a This Code of Practice for the Pharmaceutical Industry has been drawn up after consultation with the British Medical Association and the Department of Health and Social Security.

b The Code owes its origin to the determination of the Association of the British Pharmaceutical Industry to secure the acceptance and adoption of high standards of conduct in the marketing of medical products designed for use under medical supervision.

c Medical products usually owe their existence to research carried out by their manufacturers or to the development by them of results of academic research. Before a medical product is placed on the market the manufacturer will have accumulated considerable toxicological, pharmacological and clinical evidence and will have met all the statutory requirements for the testing, manufacture and marketing of that product. Comprehensive legislation has been introduced to safeguard the public by ensuring that all products meet standards of quality, efficacy and safety which are acceptable in the state of present knowledge and experience.

d It is necessary, however, for the manufacturer, operating as he does in a keenly competitive industry and serving professions for which freedom of choice is essential, to draw attention to the existence and nature of a particular product; for example, by appropriate promotional measures and the dissemination of further knowledge and experience gained in widespread use.

e While it is possible to legislate satisfactorily for the testing, manufacture and control of medical products, the Association believes that appropriate standards of

marketing conduct cannot be defined by the same means. For this reason, members of the Association have concurred in the promulgation of the Code of Practice and submitted to its restraints.

f The Code emphasises the importance in the public interest of providing the medical and allied professions with accurate, fair and objective information on medical products so that rational prescribing decisions can be made. Moreover, the Code accepts the principle that such information should be presented in a form and by ways and means which conform not only to legal requirements but also to ethical standards and canons of good taste.

The industry recognises its obligations to provide information about medical products to the pharmaceutical profession and the principles set out in this Code, therefore, apply equally to communications addressed to that profession. However, there may be instances where compliance with every provision of the Code would be inappropriate; for example, in connection with promotional material the purpose of which is to convey information of a commercial nature to pharmacists or pharmaceutical distributors.

g The Code, therefore, represents an act of self-discipline. Acceptance and observance of its provisions are a condition of membership of the Association of the British Pharmaceutical Industry. Member companies also acknowledge that the Code itself is to be applied in the spirit, as well as in the letter.

Pharmaceutical companies outside the Association are invited to accept and observe the Code because it is considered that high ethical standards should be followed throughout the whole industry if it is to maintain the confidence of all the interests which it serves.

CODE OF PRACTICE FOR THE PHARMACEUTICAL INDUSTRY

h The Code is administered by a Committee established by the Board of Management of the Association. The Committee, with an independent legally qualified Chairman from outside the industry, consists of two independent members who are medically qualified persons not engaged in the industry, and twelve members who are drawn from the senior management of member companies, including at least four medical directors or medically qualified persons of equivalent status.

The Chairman has general authority to obtain expert assistance in any field, and has an original and a casting vote.

i The Committee meets regularly to deal with complaints, to secure compliance with the Code, and to make such recommendations as it deems fit for the amendment of the provisions of the Code.

j An outstanding feature has been the success of voluntary compliance with the provisions of the Code and acceptance of the rulings of the Committee. It has not been found necessary to apply sanctions to secure compliance because members of the Association are anxious to ensure that their marketing activities conform to the highest standard.

k It is important, therefore, that the Code should accurately reflect that standard and for this reason it is kept under constant review by the Board of Management and amended from time to time where necessary to clarify it and bring it up to date. Notes for the guidance of member companies are issued periodically to keep them informed of the rulings and recommendations of the Committee and of any alterations to the Code.

l This edition of the Code supersedes all previous issues and is the fifth edition since the Code was established in 1958. It embodies the basic principles and provisions which the pharmaceutical industry believes are essential for the conduct of its marketing activities and for the maintenance of standards which are in the interests alike of the public, the medical and allied professions and the industry.

PROVISIONS OF THE CODE

The supplementary text, which appears in italics, is intended to give guidance as to the interpretation of the Code.

1 Definition of certain terms

1.1 The term 'promotion' means those informational and marketing activities, undertaken by the product licence holder or with his authority, the purpose of which is to induce the prescribing, supply or administration of his medical products. It includes, for example, the activities of representatives; various aspects of sales promotion such as journal and direct mail advertising; the use of films and other audio-visual material and exhibitions; and the provision of samples, gifts or hospitality.

The term 'promotion' does not extend to:

(i) Replies made in response to enquiries from particular doctors or to replies in response to a specific communication, whether of enquiry or comment, including letters published in a medical journal.

(ii) Announcements of pack changes, adverse reaction warnings or recall of products provided they contain no product claims.

(iii) 'Trade advertisements' as defined in the Medicines

(Advertising of Medicinal Products) Regulations 1975, i.e. catalogues, price lists or other documents issued with a view to wholesale dealing but not containing any reference to product usage other than a therapeutic classification.

By 'wholesale dealing' is meant the sale of a product to a person who, during the course of his business or professional practice, buys it for the purpose of selling it or administering it or causing it to be administered to one or more human beings.

1.2 The term 'medical product' means any unbranded or branded pharmaceutical product intended for use in humans which is promoted to the medical profession rather than directly to the lay public.

1.3 The term 'medical profession', 'practice of medicine', 'practitioner' and 'doctor' should be interpreted to extend to the dental profession and be construed accordingly.

1.4 The term 'medical representative' means a representative whose duties comprise or include calling upon members of the medical profession.

2 Methods of promotion

Methods of promotion must never be such as to bring discredit upon, or reduce confidence in, the pharmaceutical industry.

The issue of rubber stamps to doctors for use as aids to prescription writing is one of the methods of promotion barred by this clause.

3 Nature and availability of information

3.1 Upon reasonable request, the company concerned shall promptly provide members of the medical profession with accurate and relevant information about the medical products which the company markets.

3.2 Information about medical products should accurately reflect current knowledge or responsible opinion.

3.3 Information about medical products must be accurate, balanced and must not mislead either directly or by implication.

Claims for superior potency per unit weight are meaningless and best avoided unless they can be linked with some practical advantage, e.g. reduction in side-effects or cost of effective dosage.

3.4 Information must be capable of substantiation, such substantiation being provided without delay at the request of members of the medical profession.

4 Claims and comparisons

4.1 Claims for a medical product must be based on an up-to-date evaluation of all the evidence and must reflect this evidence accurately and clearly.

4.2 Exaggerated claims should not be made and all-embracing claims and superlatives avoided. Claims should not imply that a medical product, or an active ingredient, has some special merit, quality or property unless this can be substantiated.

Claims such as 'agent of choice' should be avoided unless they can be clearly substantiated.

4.3 Any statement about side-effects should be specific and based on data submitted with the licence application or notified to the licensing authority, or on published data to which references are given. It should not be stated that a product has no side-effects, toxic

hazards or risks of addiction. The word 'safe' must not be used without qualification.

4.4 The word 'new' should not be used to describe any product or presentation which has been generally available, or any therapeutic indication which has been generally promoted, for more than twelve months in the United Kingdom.

4.5 Comparisons of products must be factual, fair, and capable of substantiation. In presenting a comparison, care must be taken to ensure that it does not mislead by distortion, by undue emphasis, or in any other way.

'Hanging' comparatives, which merely claim that a product is 'better' or 'stronger' etc, should not be used.

4.6 Brand names of products of other companies must not be used unless the prior consent of the proprietors has been obtained.

5 Disparaging references

5.1 The products or services of other companies should not be disparaged either directly or by implication.

Substantiated comparative claims inviting fair comparisons with a group of products or with other products in the same field are permissible, provided that such claims are not presented in a way which is likely to mislead, whether by distortion, undue emphasis or otherwise.

5.2 The clinical and scientific opinions of members of the medical and allied professions should not be disparaged either directly or by implication.

6 Printed promotional material

6.1 The Medicines Act 1968 requires a pharmaceutical company to provide a practitioner with a data sheet before promoting a product directly to him. The content of such data sheets is determined by Regulations made under the Medicines Act.

Data Sheets for many prescription products are published in the ABPI Data Sheet Compendium which is issued at regular intervals. Copies of the Compendium are supplied to members of the medical and pharmaceutical professions.

6.2 All other printed material (including journal advertising) which is issued for promotional purposes by the product licence holder or with his authority must include certain information specified in this Code.

The requirements of Clause 6.3 or 6.4, as appropriate, must be complied with in any advertising directed towards the medical profession even if it is of a general nature, e.g. prestige advertisements listing a company's products.

An advertisement which would not otherwise conform with the Code should not be regarded as doing so by reason only of the fact that the content of the data sheet is reproduced as part of the advertisement or because a data sheet is sent with the advertisement.

6.3(i) Except for 'abbreviated advertisements', as defined in Clause 6.4, the following information must be given clearly and concisely on printed promotional material:

- a** The number of the relevant product licence and the name and address of the holder of the licence, or the business name and address of the part of his business responsible for the sale of the product.
- b** A quantitative list of the active ingredients, using approved names where such exist, or other non-proprie-

tary names; alternatively, the non-proprietary name of the product if it is the subject of an accepted monograph.

Attention is drawn to the fact that the Medicines (Advertising to Medical and Dental Practitioners) Regulations 1978 (SI 1978 No. 1020) impose additional requirements which relate to the position and type size of this information.

c At least one authorised indication for use consistent with the data sheet.

d A succinct statement of the information in the data sheet relating to the dosage and method of use relevant to the indications quoted in the advertisement and, where not otherwise obvious, the route of administration.

e A succinct statement of the side-effects, precautions and contra-indications relevant to the indications in the advertisement, giving, in an abbreviated form, the substance of the relevant information in the data sheet.

f Any warning issued by the Medicines Commission, a committee appointed under Section 4 of the Medicines Act 1968 or the licensing authority, which is required to be included in advertisements.

g The cost of a product, except in the case of advertisements in journals which have an appreciable proportion of their circulation outside the United Kingdom.

The cost of a product is the cost (excluding value added tax) of either a specified package of the product, or a specified quantity or recommended daily dose, calculated by reference to any specified package of the product.

Attention is drawn to the fact that the Medicines (Advertising to Medical and Dental Practitioners) Regulations 1978 (SI 1978 No. 1020) impose a specific requirement to that proportion of the circulation of a journal which has to be outside the United Kingdom in order to qualify for the exception to this requirement.

6.3(ii) The information required by Clause 6.3 (i) (d), (e) and (f) must be printed in such type and in such a position that its relationship to the claims and indications is readily appreciated by the reader.

6.4(i) The requirements of Clause 6.3 do not apply in the case of an 'abbreviated advertisement'. An 'abbreviated advertisement' is one, the text of which contains in relation to the product no more than:

- a** The brand name of the product.
- b** The approved names of the active ingredients, where such names exist, or other non-proprietary names; alternatively, the non-proprietary name of the product if it is the subject of an accepted monograph.

Attention is drawn to the fact that the Medicines (Advertising to Medical and Dental Practitioners) Regulations 1978 (SI 1978 No. 1020), impose additional requirements which relate to the position and type of this information.

c The name and address of the product licence holder, or the business name and address of the part of his business responsible for the sale of the product.

d One indication for use, or more than one indication provided that these are related, consistent with the data sheet.

e A concise statement, consistent with the data sheet, giving the reason why the product is recommended for such indication or indications.

f A form of words which indicates clearly that further

information is available on request to the licence holder or is to be found in the data sheet relating to the product.

6.4(ii) An 'abbreviated advertisement' must always contain the information required by Clause 6.4(i) (a), (b), (c) and (f). The information required by Clause 6.4(i) (d) and (e) is optional. An 'abbreviated advertisement' must not include any illustration which is likely to convey any information about the product or imply claims which are additional to those provided in accordance with Clause 6.4(i) (a) to (e) inclusive.

6.4(iii) An 'abbreviated advertisement' directed towards a doctor is permissible only when it constitutes an advertisement appearing in a publication sent or delivered wholly or mainly to doctors. A loose insert included in such a publication cannot be an 'abbreviated advertisement'.

Attention is drawn to the fact that the Medicines (Advertising to Medical and Dental Practitioners) Regulations 1978 (SI 1978 No. 1020) impose additional requirements which relate to the maximum permitted size of an 'abbreviated advertisement'.

6.4(iv) An 'abbreviated advertisement' is not permissible where the Medicines Commission, a committee appointed under Section 4 of the Medicines Act 1968 or the licensing authority, have required a warning to be included in any advertisement relating to the medical product, and the licensing authority have issued a direction that 'abbreviated advertisements' should not be issued.

6.5 Promotional material, such as mailings and journal advertisements, must not be designed to disguise its real nature.

Doctors rightly resent receiving promotional material in the guise of personal communications, as when advertisements are enclosed in a plain envelope or are addressed in real or facsimile handwriting on letters or postcards.

Envelopes should not be used for the dispatch of promotional material if they bear words implying that the contents are non-promotional, e.g. that the contents provide information relating to safety.

It is advisable to use first class mail only for important communications of a non-promotional nature such as notifications of warnings or cautions or the withdrawal or recall of a product.

Advertisements in journals should not be designed so as to resemble editorial matter.

6.6 Promotional material should conform, both in text and illustration to canons of good taste and should recognise the professional standing of the recipients.

Representations of the nude female form (even in silhouette) or partly clothed figures should not be used in promotional material in such a way as to arouse a visual or emotional response in order to attract attention to the text.

Displays of part of the naked body which are necessary to illustrate pictorially the message of the text are permissible provided that they conform to the dictates of decency and good taste.

6.7 Doctors' names or photographs must not be used in a prominent manner in promotional material or in any other way that is contrary to the ethical code of the medical profession.

6.8 Promotional material should not imitate the devices, copy, slogans or general layout adopted by other companies in a way that is likely to mislead or confuse.

6.9 Where appropriate, for example, in technical and other informative material, the date of printing or the last review should be stated.

6.10 Extremes of format, size or cost of printed material should be avoided.

Large size mailings which cannot be put through letter boxes are a source of irritation to doctors and should be avoided as far as possible.

6.11 Postcards, other exposed mailings, envelopes or wrappers should not carry matter which might be regarded as advertising to the lay public or which could be considered unsuitable for public view.

Postcards and other exposed mailings should not contain copy or illustrations which ought not to be read or seen by lay persons.

6.12 Telegrams must not be used for promotional purposes.

6.13 In a multi-page press advertisement in which the pages follow consecutively, only one page need include the information required by Clause 6.3 of the Code, provided that each of the other pages (except the page on which, or facing which, the information is printed) includes a reference, on an outer edge, in at least 8 point type, indicating on which page that information appears. No initial recto or final verso must be false or misleading if read in isolation.

A loose insert included in a journal is not regarded as a 'multi-page press advertisement' for the purpose of this clause.

6.14 In a multi-page advertisement other than a press advertisement, the information required by Clause 6.3 of the Code must appear on one or more continuous pages and, where such an advertisement consists of more than four pages, the advertisement must include a clear indication as to where this information may be found.

7 References to official bodies

Promotional material should not include any reference to the Medicines Commission, a committee appointed under Section 4 of the Medicines Act 1968 or the licensing authority, unless this is specifically required by the licensing authority.

8 References to the National Health Service

8.1 Where reference is made to the prescribing of a product under the National Health Service, the phrase 'freely prescribable' or similar phrases suggesting a lack of restriction or restraint must not be used.

This clause was inserted in the first edition of the Code in deference to the wishes of the then Ministry of Health. 'Freely' in this context means 'without restriction or restraint'.

Although NHS doctors are free to prescribe whatever medicines they consider necessary for the treatment of a patient, they are nevertheless required to exercise due economy.

8.2 Reproductions of official documents, such as prescription form FP 10, should not be used for promotional purposes unless the agreement of the appropriate Government department has been received.

The term 'reproduction' includes any depiction which simulates or might be taken to simulate the document in question.

9 Artwork, graphs, illustrations, etc.

9.1 Illustrations must not mislead as to the nature of the claims or comparisons being made, nor as to the purposes for which the product is used; nor should illustrations detract from warnings or contra-indications.

9.2 Artwork and graphs must conform to the letter and the spirit of the Code. Graphs and tables should be presented in such way as to give a clear, fair, balanced view of the matters with which they deal, and should only be included if they are strictly relevant to the claims or comparisons being made.

9.3 Graphs and tables must not be used in any way which might mislead; for example, by their incompleteness or by the use of suppressed zeros or unusual scales.

10 Reprints, abstracts and quotations

This clause is included to accord with the views of the Ethical Committee of the British Medical Association; its object is to avoid the risk of contravention of the BMA Code of Ethics.

10.1 Reprints of articles by members of the medical profession must not be included in mailings but may be supplied to individual doctors on request. It is permissible to include in promotional material reasonably brief abstracts of, or quotations from, articles by members of the medical profession and to include in such material reference to doctors' names in a bibliography of published works. In no case, however, should doctors' names be used in a prominent manner in promotional material.

Quotations from public broadcasts, e.g. radio and television, may not be used in promotional material. It is permissible to use quotations from private occasions, e.g. medical conferences or symposia, with the written permission of the speaker.

10.2 Quotations from medical literature, or from personal communications received from doctors, must accurately reflect the meaning of the author and the significance of the study.

10.3 The utmost care must be taken to avoid ascribing claims or views to medical authors when such claims or views no longer represent, or may not represent, the current views of the author concerned.

11 Distribution of printed promotional material

11.1 Promotional material should only be sent or distributed to those categories of persons whose need for, or interest in, the particular information can reasonably be assumed.

11.2 Any information designed to encourage the use of medical products in clinics, industrial concerns, clubs or schools must be addressed to the medical adviser or medical officer or to medical auxiliary staff.

11.3 Restraint should be exercised on the frequency of distribution and on the volume of promotional material distributed.

The style of mailings is relevant to their acceptability to doctors and criticism of their frequency is most likely to arise where their informational content is limited or where they appear to be elaborate and expensive. A higher frequency rate will be accepted for mailings on 'new' products than for others.

11.4 Mailing lists must be kept up to date. Requests from doctors to be removed from promotional mailing lists must be complied with promptly and no name may

be restored except at the doctor's request or with his permission.

12 Audio-visual material

12.1 Audio-visual material must comply with all relevant requirements of the Code, with the exception of Clause 6.3.

12.2 When audio-visual material is used to promote a product, copies of the relevant data sheet, or a document with the same content, should be made available to all persons present.

12.3 Audio-visual promotional material is subject to the certification requirements of Clause 13.

13 Certification of printed promotional material

13.1 No promotional material shall be issued unless the final text and layout have been certified by two persons on behalf of the member company in the manner provided by this Clause. One of the two persons shall be a doctor. The other shall be a pharmacist or some other appropriately qualified person or a senior official of the company. The doctor, pharmacist or other qualified person must be a senior employee of the company or an appropriately qualified person whose services are retained for that purpose.

13.2 The names of those nominated, together with their qualifications, shall be notified in advance to the licensing authority. The names and qualifications of designated alternative signatories must also be given. Changes in the names of nominees must be promptly notified.

13.3 The certificate shall certify that the signatories have examined the material in its final form and that in their belief it is in accordance with the requirements of the relevant advertising regulations and this Code of Practice, is consistent with the product licence and the data sheet, and is a fair and truthful presentation of the facts about the product.

13.4 Member companies shall preserve all certificates, together with the material in the form certified, for not less than three years and produce them upon request from the licensing authority or the Association at the instance of the Code of Practice Committee.

13.5 The foregoing procedure shall apply, with the necessary variations, to the certification of briefing material for representatives in accordance with Clause 15.12 and to audio-visual promotional material prepared by or on behalf of member companies.

14 Suspension of advertisements

In the event of the Code of Practice Committee requiring a member company to withdraw an advertisement pending its decision on a complaint by the licensing authority relevant to the safe or proper use of the product, the member company shall at once make every possible endeavour to comply.

15 Medical representatives

15.1 Medical representatives must be adequately trained and possess sufficient medical and technical knowledge to present information on the company's products in an accurate and responsible manner.

15.2 Medical representatives should at all times maintain a high standard of ethical conduct in the discharge of their duties.

15.3 The requirements of the Code which aim at accuracy, fairness, balance, good taste apply to oral representations as well as printed material.

15.4 Unfair or misleading comparisons or comparisons implying a therapeutic advantage which is not in fact justified must be avoided by medical representatives.

15.5 Claims made for products by medical representatives must be limited to the indications permitted by the product licence.

15.6 Medical representatives must not employ any inducement or subterfuge to gain an interview. No payment of a fee should be made for the grant of an interview.

The practice of gaining or extending an interview on the pretext of carrying out a survey is to be avoided. This does not preclude the use of medical representatives to obtain bona fide survey information, but it is essential that the survey should be devised and conducted so as to leave no doubt in the doctor's mind that the survey will produce medically useful information.

15.7 Medical representatives must ensure that the frequency timing and duration of calls on doctors, or on hospitals, together with the manner in which they are made, do not cause inconvenience. The wishes of an individual doctor, or the arrangements in force at any particular establishment, must be observed by medical representatives.

The number of calls made on a medical practitioner and the intervals between successive visits are relevant to the determination of frequency.

Companies should arrange that intervals between visits do not cause inconvenience to practitioners and the number of calls made by a medical representative each year should not normally exceed, on average, three visits to each doctor.

Averages are to be calculated separately for general practitioners and other members of the medical profession to whom visits are made.

The calculation should exclude:

- (i) Attendance by a medical representative at a scientific meeting or an audio-visual presentation given to a group of doctors.
- (ii) A visit which is requested by a doctor or a call which is made in order to respond to a specific enquiry.
- (iii) A visit to follow up a report of an adverse reaction.

A medical representative should not stay in a surgery in which another medical representative is already waiting, except with the doctor's or receptionist's approval.

Medical representatives must always endeavour to treat the doctor's time with the utmost respect and give him no cause to believe that his time might have been wasted. If, for any unavoidable reasons, an appointment with a doctor cannot be kept, the longest possible notice must be given.

Calls on hospital medical staff should generally be limited to matters likely to be of specific interest to them. The majority are specialists and medical representatives should ensure that their specialised interests are borne in mind. It is preferable for most hospital staff to be seen only after making a prior appointment, at which time subjects for discussion should be identified.

15.8 Medical representatives must take adequate precautions to ensure the security of medical products in their possession.

15.9 Medical representatives must not use the telephone to promote products to the medical profession unless prior arrangement has been made with individual doctors.

15.10 Medical representatives should be paid on the basis of a fixed basic salary, and any addition proportional to sales of prescription medicines should not constitute an undue proportion of their remuneration.

15.11 When discussion about a product is initiated by a medical representative, he should place before the doctor for reference either a data sheet in respect of that product or another document with the same content. If, however, the doctor asks a question about a different product, then the medical representative will not be required to produce such data in respect of that other product.

15.12 Companies must prepare detailed briefing material for medical representatives on the technical aspects of any product which the medical representative is to promote. A copy of such material must be made available to the licensing authority on request. Briefing material must comply with the relevant requirements of the Code and, in particular, is subject to the certification requirements of Clause 13.

15.13 Medical representatives should not make a claim for a product based on the regulatory treatment of that product, or of competing products, or based on any warnings issued in relation to other products, unless in accordance with a specific requirement. However, a medical representative may refer to such matters in answer to a specific question.

15.14 A company may only employ as medical representatives persons who have passed the examination established by the Association except that:

- (i) Persons with an acceptable professional qualification, e.g. in pharmacy, medicine or nursing will be exempt from this requirement.
- (ii) Persons employed as medical representatives at the date upon which this edition of the Code comes into operation will be exempt from this requirement.

The operative date for the purposes of Clause 15.14 (ii) is 1 October 1979.

- (iii) Trainee medical representatives may be employed for a period of up to two years from the date of commencing training as a medical representative.

16 Samples

16.1 Samples should be provided to a doctor only in response to a signed request unless intended solely for identification or demonstration purposes.

A company may make available to a doctor a pre-printed request form or card; such a form or card may bear no more than the doctor's name, the company's name and address and an identifying reference, together with guidance as to the further information which the doctor himself must add. This limitation as to the provision of information on a pre-printed request form or card does not apply, however, in the case of a product controlled under the Misuse of Drugs Act 1971.

If such a pre-printed form or card is presented by a representative, then the doctor himself must complete the form by inserting the requisite information.

Wherever practicable, an individual sample should not represent more than four days treatment for a single patient. When samples are provided to assist doctors in

CODE OF PRACTICE FOR THE PHARMACEUTICAL INDUSTRY

the recognition or identification of a product, or to demonstrate the use of a particular apparatus or equipment, only the minimum quantity necessary for this purpose should be supplied.

16.2 Where samples of products restricted by law to supply on prescription are distributed by a representative, the sample must be handed direct to the doctor or given to a person authorised to receive the sample on his behalf. A similar practice must be adopted for products which it would be unsafe to use except under medical supervision.

16.3 Samples of products restricted by law to supply on prescription, which are made available to representatives for distribution, should be strictly limited in quantity and an adequate system of accountability should be established.

16.4 Samples sent by post must be packed so as to be reasonably secure against the package being opened by young children.

16.5 Distribution of samples in hospitals should comply with individual hospital regulations, if any.

17 Gifts and inducements

17.1 Subject to Clause 17.2 no gift or financial inducement shall be offered or given to members of the medical profession for purposes of sales promotion.

Schemes designed to test the extent to which mailings are opened and read and which involve a reward, e.g. a reward for the return of a voucher included in the mailing, are unacceptable if the gift is one which would not come within Clause 17.2.

17.2 Gifts in the form of articles designed as promotional aids, whether related to a particular product or of general utility, may be distributed to members of the medical and allied professions provided the gift is inexpensive and relevant to the practice of medicine or pharmacy.

Amongst other items, nail brushes, book matches and pens have been held to be reasonable gifts. Gifts of table mats have been held to be in contravention of the Code as being irrelevant to the practice of medicine or pharmacy.

17.3 The requirements of Clause 6.3 or Clause 6.4 do not apply if a promotional aid of the type mentioned in Clause 17.2 bears no more than one or more of the following particulars:

- (i) The name of the product.
- (ii) The name of the product licence holder or the name of that part of his business responsible for the sale of the product.
- (iii) The address of the product licence holder or the address of the part of his business responsible for the sale of the product.
- (iv) An indication that the product name is a trade mark.

If a promotional aid consists of a note pad in which the individual pages bear advertising material, there is no need for the individual pages to comply with Clause 6 provided that the information required by the clause is given elsewhere in the pad; for example, on the cover.

18 Hospitality

Entertainment or other hospitality offered to members of the medical and allied professions for purposes of sales promotion should always be secondary to the main

purpose of the meeting. It should not extend beyond members of the professions. The level of hospitality should be appropriate and not out of proportion to the occasion; its cost should not exceed that level which the recipients might normally adopt when paying for themselves.

Medical and group meetings are desirable and are to be encouraged. Both the British Medical Association and the Association share the opinion that such meetings should only take place if the advertising content is supported by a clear educational content. If hospitality is offered at meetings attendance should be restricted to members of the medical and allied professions.

It follows, therefore, that invitations to such medical and group meetings should not be extended to wives or husbands unless they themselves are practising members of the medical or allied professions.

When organising a meeting at which hospitality will be offered, a factor to be taken into account is the impression which will be created in the minds of the recipients or those who hear about it. Hospitality which becomes little more than pure entertainment has limited value in terms of the provision of information and promotion; such hospitality can only be regarded, therefore, as irrelevant and wasteful.

19 Marketing research

Marketing research is the collection and analysis of information and must be unbiased and non-promotional. The use to which the statistics or information is put may well be promotional. The two phases should be kept distinct.

19.1 Methods used for marketing research must never be such as to bring discredit upon, or to reduce confidence in, the pharmaceutical industry. The following provisions apply whether the research is carried out directly by the company concerned or by an organisation acting on the company's behalf.

19.2 The following information must be made available to the informant at first approach:

- (i) The nature of the survey.
- (ii) The name and address of the organisation carrying out the work.
- (iii) The identity of the interviewer.
- (iv) The nature and length of the interview.

The requirement in Clause 19.2(ii) does not mean that the organisation is also obliged to reveal the identity of its client. This must depend upon the contract between the client and the organisation.

19.3 Questions intended to solicit disparaging references to competing products or companies must be avoided.

19.4 Any written or oral statement given or made to an informant in order to obtain co-operation must be both factually correct and honoured.

19.5 Any incentives offered to the informants should be kept to a minimum and be commensurate with the work involved.

19.6 Marketing research must not in any circumstances be used as a disguised form of sales promotion and the research *per se* must not have as a direct objective the influencing of the opinions of the informant.

19.7 The identity of an informant must be treated as being confidential, unless he has specifically agreed otherwise.

CODE OF PRACTICE FOR THE PHARMACEUTICAL INDUSTRY

In the absence of this agreement it follows that the information provided (as distinct from the overall results of the research) must not be used as the basis upon which a subsequent approach is made to that informant for the purpose of sales promotion.

19.8 Precautions should be taken to ensure that no embarrassment results for informants following on from an interview, or from any subsequent communication concerning the research project.

20 Relations with the general public and lay communication media

20.1 Requests from individual members of the public for information or advice on personal medical matters must always be refused and the enquirer recommended to consult his or her own doctor.

20.2 Medicines which cannot legally be sold or supplied to the public otherwise than in accordance with a prescription, or which are legally limited to promotion for sale or supply only on prescription, must not be advertised to the general public.

Posters or notices issued for display in doctor's surgeries, pharmacies or anywhere to which the public have access must not include any message likely to arouse a demand for any particular product.

20.3 Statements must never be designed or made for the purpose of encouraging members of the public to ask their doctor to prescribe a product.

20.4 Information about medical products or matters related thereto, including scientific discoveries or advances in treatment, should not in general be made available to the general public either directly or through any lay medium.

The intention is to ensure that arrangements made for a press conference, or the extent of a press release, are such as to confine the disclosure of information about medical products or matters relating thereto to persons who are capable of evaluating the information responsibly and not concerned to exaggerate or even sensationalise its significance.

20.5 The importance of such information and the existence of legitimate public interest in acquiring it may exceptionally justify holding a press conference or the issue of a press release.

Invitations to attend such a conference, or the distribution of such a press release, should be confined

to persons who are either medically qualified or established as the representatives of the medical, pharmaceutical or scientific press, or as the medical correspondents of a responsible medium.

In the circumstances set out above as to the significance of the information, and in response to an unsolicited enquiry from a person of the standing described, information may also be released in an informal manner.

20.6 A further exception may arise when there exists a genuine mutual interest of a financial or commercial nature justifying the disclosure of information about medical products or related matters privately or to a restricted public. Examples are the interests of shareholders, financial advisers, employees and creditors.

When releasing information, it is essential to bear in mind the provisions of Clause 4.3 and, in particular, the extreme caution required in any reference to side-effects; it should also be emphasised that the treatment of a particular individual is solely a matter for decision by his medical practitioner.

20.7 On all occasions the information whether written, or communicated by other means, must be presented in a balanced way so as to avoid the risk of raising unfounded hopes of successful treatment or stimulating the demand for prescription of the particular product.

20.8 An announcement of the introduction of a new medical product must not be made by press conference or formal press release until the appropriate steps have been taken to inform the medical profession of its availability.

21 Transitional provisions

21.1 This Revised Fifth Edition of the Code shall not take effect:

(i) Until 1 October 1982, in relation to any advertisement consisting of four or more pages or advertising on a promotional aid, printed before 1 December 1978 and sent through the post or otherwise delivered to a doctor or a dentist.

(ii) Until 1 April 1982, in relation to any other advertisement and any other matter.

21.2 Until this Code takes effect in relation to any advertisement to which Clause 21.1 (i) applies, the requirements of the Fourth Edition of the Code shall continue to apply to that advertisement.

Abbott Laboratories Limited

Queenborough

Kent ME11 5EL

ABBOCIN®

Presentation Each yellow, sugar-coated tablet contains 250 mg Oxytetracycline Dihydrate BP.

Uses Organisms sensitive to oxytetracycline include a large number of Gram-negative and Gram-positive pathogenic bacteria. Those organisms that are sensitive to tetracycline in the concentrations usually achieved in the body during treatment are *Bacillus anthracis*, *Brucella* spp., *Escherichia coli*, *Haemophilus* spp., *Klebsiella* spp., *Proteus vulgaris*, staphylococci, streptococci, mycoplasma, *Entamoeba histolytica*, *Trichomonas vaginalis*, certain rickettsias and larger viruses. *Pseudomonas aeruginosa*, salmonella spp., and *Mycobacterium tuberculosis* are less susceptible.

Dosage and administration For adults and older children the dose is 250 mg four times daily taken orally. In severe infections this dose may be doubled or trebled.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the tetracyclines.

Precautions and side-effects: As with other tetracyclines, Abbocin should be administered with great care to individuals with renal or hepatic dysfunction. Because of the staining of teeth and effects on bone development, tetracyclines should not be given in pregnancy or to children under 12 years of age. Tetracyclines should not be administered simultaneously with milk, antacids or preparations containing iron, calcium or magnesium.

Side-effects include nausea, diarrhoea and symptoms resulting from the overgrowth of non-susceptible organisms. Overgrowth of *Candida albicans* in the mouth may cause glossitis and stomatitis which may extend into the trachea and bronchi; overgrowth of *C. albicans* in the bowel results in pruritis ani; overgrowth of resistant coliform organisms such as pseudomonas and proteus may also cause diarrhoea. Occasionally resistant staphylococci may give rise to a fulminating enterocolitis. Allergic reactions and skin rashes are rare.

Treatment of overdose: Gastric lavage. Intensive supportive therapy. In cases of overdose, allergic reactions such as drug fever, anaphylactic shock and rash may occur. For treatment of anaphylaxis immediate administration of adrenaline, oxygen and artificial respiration is necessary.

Adrenaline is given subcutaneously as 0.5–1 ml adrenaline Injection BP 0.1%. For dyspnoea, aminophylline, calcium and antihistamines may be given. General measures, such as administration of plasma, blood, vasopressor drugs or hydrocortisone (100 mg IV) may be necessary.

Incompatible with alkalis and chloramphenicol.

Pharmaceutical precautions Store below 25°C. Keep container tightly closed.

Legal category POM.

Package quantities Abbocin is supplied in containers of 1,000 sugar-coated tablets.

Further information Metabolisable carbohydrate content approx 0.29 g per tablet.

Product licence number 0037/0095.

ABBOKINASE® ▼

Presentation Abbokinase is a highly purified sterile lyophilised formulation of urokinase obtained from cultures of human kidney cells. Urokinase is a plasminogen activator excreted in the urine of normal healthy individuals. Each vial of Abbokinase contains in excess of 250,000 iu so that, following reconstitution with 5.2 ml sterile water for injection, each ml of the 5 ml which can be withdrawn will contain 50,000 iu urokinase, 5 mg mannitol and 5 mg sodium chloride.

Uses Abbokinase *in-vivo* and *in-vitro* produces the release of plasmin by an enzymatic action on human plasminogen.

Abbokinase has only minimal activity in reducing fibrinogen levels but blood plasminogen levels are reduced, the effect being dose-dependent.

Abbokinase is virtually non-antigenic to humans and, in therapeutic doses, is thromboplastin-free.

Thrombolytic therapy is indicated in the treatment of vascular occlusions caused by forming or recently formed fibrin clots. Theoretically the best results will be obtained with thrombi less than 24 hours old.

Abbokinase is indicated as a thrombolytic agent in pulmonary embolism.

Dosage and administration Abbokinase is administered intravenously by continuous infusion, usually for a period of 12 hours.

It is recommended that Abbokinase be given in a solution of normal saline by constant infusion. An initial loading dose to be given during the first ten minutes of therapy is advocated.

This loading dose should be equal to the amount which it is planned to administer over each succeeding period of one hour. Ideally, an infusion pump should be used to maintain a constant rate of infusion.

Abbokinase is reconstituted with 5.2 ml sterile water for injection, without preservatives.

For administration the reconstituted solution should be further diluted with normal saline. It is strongly recommended that the total volume after dilution should be 195 ml, irrespective of the number of vials used, since this provides for a bolus dose of 15 ml followed by the infusion of 15 ml per hour over 12 hours. However, choice of another volume is possible, the physician being guided by considerations of possible effect on the patient of larger volumes and physical difficulties of measurement with smaller volumes. A chart is available detailing volumes of reconstitution and further dilution for use (on

Figure – Number of vials of Abbokinase required according to patient weight and data for reconstitution and further dilution.

the basis of a final volume of 195 ml) in cases where the amount of Abbokinase immediately available is less than that required for the total treatment.

Dosage: It should be noted that patient-to-patient variation in response can be expected, due to individual variation in levels of inhibitory factors. Certain disease states such as uraemia, some malignancies and dyslipidaemias can be associated with an increased plasma level of urokinase or plasmin inhibitors. In other conditions such as massive pulmonary embolism, endogenous fibrinolytic activity may be increased.

The recommended dosage regimen for the treatment of pulmonary embolism is:

Loading dose – 4,400 iu per kg body weight over 10 minutes.

Constant infusion dose – 4,400 iu per kg body weight per hour.

Duration of infusion – 12 hours.

Contra-indications, warnings, etc

Contra-indications: Manifest or recent (i.e. within three days) haemorrhage. Any haemorrhagic diathesis. Severe hypertension. During cardiopulmonary resuscitation. During pregnancy or suspected pregnancy. Menstruation.

Warnings and precautions: The major adverse effect of Abbokinase is haemorrhage, usually associated with too high dosage. A high incidence of bleeding from minor skin lesions, therapeutic and diagnostic puncture sites and pre-existing gastro-intestinal lesions has been observed with high dosages. Any evidence of significant internal bleeding necessitates the cessation of thrombolytic therapy. An antifibrinolytic agent such as tranexamic acid may be used as an antidote if required. It should be available, if necessary, during infusions with Abbokinase when high doses are being administered.

Post-surgery for one month.

Recent surgery (within three days).

Concurrent anticoagulant therapy should be administered cautiously.

Mild temperature increases have been observed during thrombolytic therapy with Abbokinase.

When there is a history of hypersensitivity to drugs, etc., caution is advised and resuscitatory facilities as well

as corticosteroids, adrenaline etc. should be readily available when Abbokinase is infused.

Monitoring: The monitoring of fibrinolytic activity, thrombin clotting time and of plasminogen levels is desirable.

Pharmaceutical precautions The lyophilised powder should be stored at 2–8°C. Reconstituted solution should be used immediately, but the secondarily diluted product in normal saline can be preserved at room temperature, if necessary, for up to 24 hours.

Legal category POM.

Package quantities Available in packs of 2 vials of 250,000 iu each.

Further information The potency of Abbokinase is expressed in International Units (iu). For practical purposes the iu is considered by most authorities to be equivalent to the CTA unit.

The Ploug unit is usually considered to be equal to 1.4 iu.

Product licence number 0037/0096.

AKINETON®

Presentation Akineton is supplied in white scored tablets, with a triangle on the opposite side, containing 2 mg biperiden hydrochloride. Also available in 1 ml ampoules containing 5 mg of biperiden lactate.

Uses In drug-induced extrapyramidal symptoms and all other types of parkinsonism. It is particularly effective against rigidity.

Dosage and administration **Adults:**

1. **Tablets:** Begin with $\frac{1}{2}$ tablet twice daily and gradually increase to 1 tablet thrice a day. After maintenance at this level for a few days, gradually increase until no further symptomatic improvement is obtained. Decrease cautiously to lowest dosage which adequately controls symptoms. The optimum maintenance dose varies from 3–12 mg daily.

2. Ampoules: 1–4 ampoules daily slowly intravenously or intramuscularly.

Children: Not recommended.

Notes:

1. When salivation is reduced the tablets are best taken after meals, in other cases they should be taken during meals.

2. With parenteral administration, the systolic blood pressure may be decreased by 20–30 mm Hg and the diastolic by 5–20 mm Hg.

3. **Combined treatment:** In some cases the response of tremor to the drug may be inadequate. In such cases combined therapy with a preparation effective against tremor should be considered. However, it is advisable to continue with Akineton alone until it has been established that its effect on tremor is inadequate.

4. **Reversal effect:** An increase in parkinsonism symptoms during treatment is a preliminary sign of intoxication due to excessive dosage and should be treated by reduction of the dose.

Contra-indications, warnings, etc

Contra-indications: Sensitivity to Akineton (Biperiden hydrochloride). Narrow angle glaucoma. Intestinal obstruction.

Precautions: Care should be taken when administering Akineton to patients with cardiac arrhythmias. Patients with recent myocardial infarction should be given Akineton only if the heart rate is well controlled.

Occasionally drowsiness may occur, and patients who drive a car or operate any other potentially dangerous machinery which requires concentration should be warned that side-effects of this type are a possibility. As with other drugs acting on the central nervous system, the consumption of alcohol should be avoided during Akineton therapy.

As with every other long-term medication regular blood counts are recommended.

Treatment with Akineton should not be discontinued abruptly. Transfer of patients to Akineton from other anti-parkinsonism agents should be made gradually, the original agent being reduced in dose as Akineton is substituted.

Use during pregnancy: The potential benefits of Akineton therapy should be weighed against possible hazards to the patient as well as to the foetus. No data are available regarding continuous administration in pregnant patients.

Side-effects: Akineton is well tolerated and side-effects are minimal even with prolonged usage. Dryness of the mouth, disturbances of accommodation, fatigue and vertigo may occur. In general these symptoms disappear in a few days without change in dosage; in a few cases a reduction of the dose may be needed, but discontinuation is seldom required. Gastro-intestinal symptoms can be prevented, in most cases, by administering Akineton during or after a meal.

Restlessness, confusion and euphoria may occur, but the incidence is low. Occasionally drowsiness may occur.

On rare occasions, particularly in patients with hypertrophy of the prostate, disturbances of micturition may occur and, even more rarely, retention of urine. Reduction of dosage will usually restore the bladder function to normal.

Overdosage: **Symptoms:** respiratory and cardiac depression.

Treatment: Gastric lavage or emesis should be considered. Vital signs should be closely monitored and appropriate supportive measures taken. Artificial ventilation may be necessary. In the event of cardiac depression, a cardiac stimulant such as dobutamine may be considered.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Akineton 2 mg tablets are supplied in containers of 50.

Akineton ampoules are supplied in boxes of 5 × 1 ml ampoules.

Further information *Metabolisable carbohydrate content:* Approx. 0.16 g per tablet.

Sodium content: 0.13 mmol per ampoule (0.13 mmol per ml).

Tablets 0037/5900

Ampoules 0037/5901

CO-FRAM* ▼

© *Approved name:* Co-trifamole

Presentation White, scored tablets each containing 80 mg trimethoprim BP and 400 mg sulphamoxole. Each tablet bears the  logo.

Uses Treatment of infections caused by a wide range of gram-positive and gram-negative organisms. Co-Fram is particularly indicated in the treatment of the following:

Urinary tract infections, including pyelonephritis, pyelitis and cystitis.

Genital tract infections, including prostatitis and non-gonococcal urethritis.

Gastro-intestinal tract infections, such as enteritis, enterocolitis, bacterial dysentery and salmonella infections including typhoid and paratyphoid fevers.

Skin infections, including pyoderma, abscesses, wound infections, furunculosis.

Respiratory tract infections, including acute and chronic bronchitis, pneumonia, broncho-pneumonia, bronchiectasis.

Ear, nose & throat infections, such as tonsillitis, otitis media, sinusitis and pharyngitis.

Other infections due to sensitive pathogens.

Dosage and administration **Adults:** Two tablets initially followed by one tablet every twelve hours. Treatment should continue until two days after the disappearance of all clinical signs of infection.

Children (6–12 years): 1–1½ tablets initially followed by ½–1 tablet every 12 hours. Treatment should continue until 2 days after the disappearance of all clinical signs of infection.

Contra-indications, warnings, etc

Contra-indications: Co-Fram is contra-indicated in severe renal insufficiency where repeated measurements of the plasma sulphonamide concentration are not practicable.

Co-Fram is contra-indicated in patients with severe hepatic disorders or blood dyscrasias.

Co-Fram should not be given to patients with a history of sulphonamide or trimethoprim sensitivity.

Co-Fram should not be given during pregnancy nor should it be given to premature babies or during the first four months of life. The usual caution in prescribing any drug for women of child-bearing age should be exercised with Co-Fram.

Under adverse circumstances Co-Fram could impair folic acid metabolism in humans. Therefore use in patients with haemopoietic disorders should be avoided.

Precautions: It is important to ensure that the patient has an adequate fluid intake. In particular, there must be an adequate daily volume of urine in patients with dehydration due to severe loss of fluid associated with vomiting, diarrhoea and persistent fever. Substances which acidify the urine should not be given during treatment with Co-Fram.

In severe renal insufficiency dosage should be reduced or the interval between doses extended to avoid accumulation of the drug; plasma concentrations of sulphonamide must be monitored during treatment in order to establish optimum dosage.

The blood picture should be checked during long-term treatment with Co-Fram in order to detect possible cases of folic acid deficiency.

Side-effects: Gastro-intestinal side-effects and skin reactions may occur in a small proportion of patients. The possibility of blood dyscrasias of the sort associated with other preparations containing sulphonamides should be borne in mind, particularly in the elderly.

Treatment of overdosage: Gastric lavage and general supportive measures. Forced diuresis and alkalisation of the urine will aid elimination of sulphamoxole. Calcium folinate 3–6 mg for 5–7 days given intramuscularly will counteract the effects of trimethoprim on haemopoiesis.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Containers of 100 tablets.

Further information Metabolisable carbohydrate 75 mg per tablet.

Product licence number 0037/0099

CORDILOX* 120 CORDILOX*

Presentation Cordilox 120 is presented as a yellow Filmtab* (film-coated tablet, Abbott) containing 120 mg Verapamil Hydrochloride BP. Cordilox is also available as yellow Filmtabs containing 40 mg and 80 mg Verapamil Hydrochloride BP. Cordilox 120 and Cordilox are Verapamil Hydrochloride Tablets BP.

Uses Cordilox is a calcium antagonist which blocks the inward movement of calcium in cardiac muscle cells, in smooth muscle cells of the coronary and systemic arteries and in the cells of the intracardiac conduction system. The decrease in systemic and coronary vascular resistance and the sparing effect on intracellular oxygen consumption appear to explain the anti-anginal properties of the product.

Because of its effect on the movement of calcium in the intracardiac conduction system, it reduces automaticity, decreases conduction velocity and increases the refractory period.

Cordilox reduces both systolic and diastolic blood pressure by mechanisms which have not been fully determined.

Cordilox is clinically useful in:

- (1) the treatment and prophylaxis of angina pectoris.
- (2) the treatment and prophylaxis of supraventricular tachycardia (paroxysmal tachycardia, premature supraventricular contractions, atrial fibrillation and flutter) and paroxysmal supraventricular tachycardia, of the reciprocating type, associated with the Wolff-Parkinson-White syndrome.
- (3) the treatment of mild to moderate hypertension and of renal hypertension, used alone or in conjunction with other antihypertensive therapy.

Dosage and administration

1. **Angina: Adults:** 120 mg t.d.s. is recommended. 80 mg t.d.s. can be completely satisfactory in some patients with angina of effort. Less than 120 mg t.d.s. is not likely to be effective in angina at rest and variant angina.

2. **Supraventricular Tachycardias: Adults:** 40–120 mg t.d.s. according to the severity of the condition (in acute cases, Cordilox i.v. is indicated).

Children: Up to 2 years: $\frac{1}{2}$ 40 mg tablet 2–3 times a day.

2 years and above: 1–3 40 mg tablets, 2–3 times a day, according to age and effectiveness.

3. **Hypertension: Adults:** The usual dose range is 80–160 mg t.d.s. The dose should be increased from 80 mg t.d.s. at weekly intervals according to response, either alone or in conjunction with other antihypertensive therapy. A further reduction in blood pressure may be obtained by combining Cordilox with other antihypertensive agents, e.g. thiazide diuretics.

Children: up to 10 mg/kg/day in divided doses, according to severity of disease.

Contra-indications, warnings, etc *Contra-indications:* Hypotension associated with cardiogenic shock, marked bradycardia (less than 50 beats/minute), second or third degree atrioventricular block, sick sinus syndrome, uncompensated heart failure.

Precautions: Cordilox may affect impulse conduction and should be used with caution in patients with first degree atrioventricular block. The effects of Cordilox and beta blockers may be additive both with respect to conduction and contraction, therefore care must be exercised when these are administered concurrently or closely together. This is especially true when either drug is administered intravenously.

Cordilox may affect left ventricular contractility as a result of its mode of action. This effect is small and normally not important but cardiac failure may be precipitated or aggravated if it exists. In cases with poor ventricular function therefore Cordilox should only be given after appropriate therapy for cardiac failure such as digitalis, etc.

Verapamil hydrochloride has been shown to increase the serum concentration of digoxin and caution should be exercised with regard to digitalis toxicity.

Caution should be observed in the acute phase of myocardial infarction.

In patients with impaired liver function, particular attention should be paid to the dosage because of reduced drug metabolism.

Although animal studies have not shown any teratogenic effect, Cordilox should not be given during the first

trimester of pregnancy unless, in the clinician's judgement, it is essential for the welfare of the patient.

Side-effects: Cordilox is generally well-tolerated. Constipation is not uncommon, flushing is observed occasionally, headaches rarely. Nausea and vomiting have seldom been reported and allergic reactions even more rarely.

Overdosage: Usual emergency measures for acute cardiovascular side-effects should be applied, e.g.:

- in the case of cardiac arrest, heart massage, mechanical respiration, followed by appropriate intensive care;
- in the case of the second and third degree AV block, atropine, isoprenaline and, if required, pace-maker therapy;
- in the case of signs of myocardial insufficiency, dopamine, dobutamine, cardiac glycosides or calcium gluconate (10–20 ml of a 10% solution);
- in the case of hypotension, appropriate positioning of patient, dopamine, dobutamine, noradrenaline.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Cordilox 120 is supplied in containers of 100 and 500 tablets.

Cordilox 40 and 80 mg are supplied in containers of 100 tablets.

Further information Metabolisable carbohydrate content: Cordilox 120: approx. 0.12 g per tablet; Cordilox 40 mg and 80 mg: approx. 0.04 g and 0.08 g per tablet respectively.

Product licence numbers

Cordilox 120	0037/0084
Cordilox 40 mg	0037/0098
Cordilox 80 mg	0037/0085

CORDILOX* I.V.

Presentation Cordilox for intravenous administration (Verapamil Hydrochloride Injection BP) is available in 2 ml ampoules each containing 5 mg verapamil hydrochloride.

Uses Cordilox slows AV nodal conduction. This is due to a specific inhibitory effect on the transmembrane passage of calcium ions. Simultaneously, it diminishes the peripheral resistance and so relieves the work load on the heart.

Clinically, Cordilox decreases myocardial oxygen consumption and increases exercise tolerance.

Cordilox is effective in the treatment of supraventricular arrhythmias.

Dosage and administration *By intravenous injection:* For the treatment of tachyarrhythmias 5–10 mg (1–2 ampoules) should be injected over a period of 30 seconds intravenously, with continuous observation of the patient.

In cases of paroxysmal tachyarrhythmias a further 5 mg may, if necessary, be injected 5–10 minutes after the first injection with the same precautions being observed.

Higher doses are not usually necessary.

By intravenous infusion: 5–10 mg of Cordilox per hour may be administered in saline, glucose, laevulose, or similar solutions, until a total dose varying between 25–100 mg per day is reached.

Intravenous dosage in children: *Newborn:* 0.75–1 mg (0.3–0.4 ml).

Infants: 0.75–2 mg (0.3–0.8 ml).

Children aged 1–5 years: 2–3 mg (0.8–1.2 ml) *6–15 years:* 2.5–5 mg (1.0–2.0 ml).

In many cases smaller doses than those mentioned above are sufficient. The injection should be stopped at the onset of the desired effect.

Intravenous injection should desirably be made – and in infancy always – under electrocardiographic control. If necessary, the same dose may be repeated after 5–10 minutes.

Contra-indications, warnings, etc *Contra-indications:* Hypotension associated with cardiogenic shock, marked bradycardia (less than 50 beats/minute), uncompensated heart failure.

Precautions: Cordilox may affect impulse generation or conduction. Thus its use should be cautionary in, for instance, sick sinus syndrome, AV block and patients with prolonged P-R intervals, etc.

Cordilox may affect ventricular contractility as a result of its mode of action. This effect is small and normally not important but cardiac failure may be precipitated or aggravated if it exists. In cases with poor ventricular function therefore Cordilox should only be given after appropriate therapy for cardiac failure such as digitalis, etc.

Verapamil hydrochloride has been shown to increase the serum concentration of digoxin and caution should be exercised with regard to digitalis toxicity.

Caution should be observed in the acute plasma phase of myocardial infarction.

In patients with impaired liver function, particular attention should be paid to the dosage because of reduced drug metabolism.

Although animal studies have not shown any teratogenic effect, Cordilox should not be given during the 1st trimester of pregnancy unless, in the clinician's judgement, it is essential for the welfare of the patient.

Side-effects: Parenteral Cordilox is well tolerated and does not exert a bronchoconstrictor effect.

Due to the mode of action, undesired effects on atrioventricular conduction and blood pressure are possible. This applies particularly to patients with atrioventricular block and/or considerably impaired myocardial function. On rare occasions the intravenous administration of Cordilox may lead to an undesired blocking of conduction, and, in extreme cases, to asystole. The asystole is usually of short duration and cardiac action returns spontaneously after a few seconds, usually in the form of sinus rhythm. However, if on rare occasions this pattern does not ensue, treatment should be carried out as described below.

Cordilox may have an additive effect with other antihypertensive drugs. Thus, in many cases, with Cordilox, a reduction in dose of the antihypertensive drug is possible. During the simultaneous administration of Cordilox and drugs with cardiodepressive effect and/or inhibiting effect on atrioventricular conduction (e.g. beta-adrenergic blocking substances, quinidine), watch should be kept for additive effects.

Intravenous administration of Cordilox may lead to a slight transient fall in blood pressure due to a reduction of peripheral resistance. Rarely this may result in severe hypotension.

Ventricular fibrillation may be precipitated on very rare occasions.

Treatment of acute cardiovascular side-effects: If acute complications occur after the intravenous injection of Cordilox (asystole, total atrioventricular block, or ventricular fibrillation) the usual emergency measures should be applied e.g. cardiac massage, mechanical respiration, the intravenous or intra-cardiac injection of adrenaline, and the intravenous injection of 10–20 ml of calcium gluconate 10% solution. In the event of ventricular asystole usual resuscitative measures should be used. Hypotension following intravenous injection of Cordilox may, if necessary, be controlled without difficulty by the use of vasoconstrictor substances.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Cordilox ampoules are supplied in boxes of 5 × 2 ml ampoules, each ampoule containing 5 mg Verapamil Hydrochloride BP.

Further information *Sodium content:* 0.30 mmol per ampoule (0.15 mmol per ml).

Product licence number 0037/5903.

ENDURON*

Presentation Each square, pink, grooved tablet contains 5 mg methyclothiazide.

Uses Enduron is indicated as a primary measure in the treatment of mild to moderate hypertension and as an adjunct to other drugs in the treatment of resistant hypertension. It is also indicated in the same clinical situations in which benzothiadiazines are of value. It is used in the treatment and control of oedema associated with congestive heart failure, the nephrotic syndrome, hepatic cirrhosis, pre-menstrual tension and the administration of steroids. The use of Enduron permits a reduction in the dosage of more potent antihypertensive agents with a consequent reduction in side-effects.

Dosage and administration The usual oral dosage is 2.5–5 mg daily. This may be increased to 10 mg once daily, if necessary, but doses larger than 10 mg have little additional therapeutic effect.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to thiazide derivatives. It should not be administered in the presence of severe renal or hepatic disease.

Precautions and side-effects: Although the incidence of side-effects with Enduron is extremely low, it is a benzothiadiazine derivative, and the physician should be alert for the side-effects inherent in this type of medication. If potassium depletion occurs, citrus fruit juices should be taken regularly to supplement potassium intake. Patients on digitalis, on corticosteroids, or with impending hepatic coma, cirrhotic oedema or ascites may require potassium supplements, and should be carefully evaluated clinically. Hypochloraemic alkalosis is a possibility with any potent benzothiadiazine, but remote with Enduron because it produces approximately equivalent sodium and chloride excretion. Elevation of

the blood urea nitrogen, serum uric acid and blood sugar have occurred with the use of thiazide drugs. Myocardial sensitivity to digitalis is increased in the presence of reduced potassium uptake and signs of digitalis intoxication may be produced by formerly tolerated doses of digitalis. Blood dyscrasias including thrombocytopenia with purpura, agranulocytosis and aplastic anaemia have also been reported but are rare.

Overdosage: Symptoms: electrolyte imbalance. Dehydration. Hypotension. Signs of potassium deficiency including confusion, dizziness, muscular weakness and gastro-intestinal disturbances may occur.

Treatment: Employ general supportive measures. Replacement of fluids and electrolytes may be indicated.

For recent ingestion gastric lavage or emesis should be considered.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Enduron is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.18 g per tablet.

Product licence number 0037/5028.

ENDURONYL*

Presentation Each square, grooved, yellow Enduronyl tablet contains:

Methyclothiazide	5 mg
Deserpidine	0.25 mg

Also available as Enduronyl Forte in square, grooved, ing:

grey tablets, each containing:

Methyclothiazide	5 mg
Deserpidine	0.5 mg

Uses In the treatment of hypertension.

Dosage and administration One half to two tablets Enduronyl or Enduronyl Forte daily. The dosage should be determined by individual titration of ingredients. Dosage of both components should be carefully adjusted to the needs of the individual patient. Usual daily dosage of Enduronyl or Enduronyl Forte 1 tablet. Grooved tablets are provided to permit considerable latitude in meeting dosage requirements of individual patients. Therapy should be initiated with 1 Enduronyl tablet daily even in patients with severe hypertension. This dosage may be increased to 2 tablets daily, depending upon the result of the initial dosage. Usually a period of ten days to two weeks of therapy is required to determine the full effects of a given dosage. In all cases an effort should be made to determine the lowest effective dose for each patient. A dosage as low as ½-tablet of Enduronyl, once a day, may suffice, whereas up to the maximum of 2 tablets may be required in some cases. Occasionally it may be possible to reduce the dosage when control has been obtained with maximum doses. If Enduronyl is administered with other antihypertensive agents the initial dosage of these drugs should be halved.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to the thiazide derivatives. Enduronyl should not be administered in the

presence of severe renal or hepatic disease. Because of the deserpidine content, Enduronyl is also contra-indicated in patients with mental depression and suicidal tendencies, active peptic ulcer or ulcerative colitis.

Precautions and side-effects: The low incidence of side-effects observed with the use of Enduron and Harmony (deserpidine) individually is applicable to their combined use in Enduronyl. Moreover, the combination exerts equivalent antihypertensive effect, with lesser amounts of each drug than when they are given singly. Nevertheless, the physician should be alert for the side-effects inherent in this type of medication.

Overdosage – Enduron (methyclothiazide)

Symptoms: Electrolyte imbalance. Dehydration. Hypotension. Signs of potassium deficiency including confusion, dizziness, muscular weakness and gastrointestinal disturbances may occur.

Treatment: Employ general supportive measures. Replacement of fluids and electrolytes may be indicated.

For recent ingestion gastric lavage or emesis should be considered.

Harmony (deserpidine)

Symptoms: Mental depression, hypotension, ptosis, miosis and catatonia in severe cases.

Treatment: Suggested treatment is the administration of methylamphetamine hydrochloride 5–15 mg orally for adults. More severe cases will require 10–30 mg intravenously or intramuscularly. Treatment should be initiated with the smaller dose. For children these doses must be reduced in proportion to body weight.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Enduronyl is supplied in containers of 100 and 500 tablets.

Enduronyl Forte is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Enduronyl, approx. 0.18 g per tablet.

Enduronyl Forte, approx. 0.18 g per tablet.

ERYTHROMID*

Presentation Each 250 mg orange coloured enteric-coated Filmtab* (film-coated tablet Abbott) contains 250 mg erythromycin base. They are Erythromycin Tablets BP.

Uses For the prophylaxis and treatment of infections caused by erythromycin-sensitive organisms.

Clinical indications: Erythromid is highly effective in the treatment of a great variety of clinical infections.

1. **Upper respiratory tract infections:** tonsillitis, peritonsillar abscess, pharyngitis, laryngitis, sinusitis, secondary infections in colds and influenza.

2. **Lower respiratory tract infections:** Tracheitis, acute and chronic bronchitis, pneumonia (lobar pneumonia, bronchopneumonia, primary atypical pneumonia), bronchiectasis, legionnaires' disease.

3. **Ear infections:** Otitis media and otitis externa, mastoiditis.

4. **Oral infections:** Gingivitis, Vincent's angina.

5. **Eye infections:** Blepharitis.

6. **Skin and soft-tissue infections:** Boils and carbuncles, paronychia, abscesses, pustular acne, impetigo, cellulitis, erysipelas.

7. **Gastro-intestinal infections:** Cholecystitis, staphylococcal enterocolitis.

8. **Prophylaxis:** Pre- and post-operative, trauma, burns, rheumatic fever.

9. **Other infections:** Osteomyelitis, urethritis, gonorrhoea, syphilis, lymphogranuloma venereum, diphtheria, prostatitis, scarlet fever.

Note: The antibiotic has also proved to be of value in endocarditis and septicæmia, but in these conditions initial administration of erythromycin lactobionate by the intravenous route is advisable.

Microbiological indications: Erythromid is active against a wide variety of pathogenic organisms, Gram-positive cocci – staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, corynebacteria, neisseria, *Treponema pallidum*, bordetella.

Note: The majority of strains of *Haemophilus influenzae* are susceptible to the concentrations reached after ordinary doses.

Dosage and administration *Adults and older children:* Usual oral dosage 1 tablet every four to six hours, increased to 4 g or more per day in unusually severe infections.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to erythromycin.

Precautions: Erythromycin is excreted principally by the liver, so caution should be exercised in administering the antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy and it has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Side-effects: There are very few side-effects to any Abbott erythromycin product. There are no reports implicating them with abnormal tooth development and only rare reports of damage to the blood, kidneys, liver or central nervous system. Allergic reactions are rare and mild, although anaphylaxis has occurred. Occasionally there is abdominal discomfort after oral administration, sometimes with nausea and vomiting. It usually subsides after a few days without having to reduce the dosage. The rare possibility of superinfection caused by overgrowth of non-susceptible bacteria or fungi should be kept in mind during prolonged or repeated therapy, especially when other antibacterial agents are simultaneously employed.

Overdosage: **Symptoms:** nausea, vomiting, diarrhoea.

Treatment: Gastric lavage, general supportive measures.

Pharmaceutical precautions Keep bottle tightly closed. Protect from light and store below 30°C.

Legal category POM.

Package quantities Erythromid is supplied in containers of 100, 500 and 1000 tablets.

Further information Contains no metabolisable carbohydrate.

Product licence number 0037/5019.

ERYTHROCIN® 250

Presentation Each 250 mg Erythrocin white Filmtab® (film-coated tablet Abbott) contains 250 mg erythromycin activity as Erythromycin Stearate BP.

Uses For the prophylaxis and treatment of infections caused by erythromycin-sensitive organisms.

Clinical indications: Erythrocin is highly effective in the treatment of a great variety of clinical infections.

1. **Upper respiratory tract infections:** Tonsillitis, peritonsillar abscess, pharyngitis, laryngitis, sinusitis, secondary infections in colds and influenza.
2. **Lower respiratory tract infections:** Tracheitis, acute and chronic bronchitis, pneumonia (lobar pneumonia, bronchopneumonia, primary atypical pneumonia), bronchiectasis, legionnaires' disease.
3. **Ear infections:** Otitis media and otitis externa, mastoiditis.
4. **Oral infections:** Gingivitis, Vincent's angina.
5. **Eye infections:** Blepharitis.
6. **Skin and soft-tissue infections:** Boils and carbuncles, paronychia, abscesses, pustular acne, impetigo, cellulitis, erysipelas.
7. **Gastro-intestinal infections:** Cholecystitis, staphylococcal enterocolitis.
8. **Prophylaxis:** Pre- and post-operative, trauma, burns, rheumatic fever.
9. **Other infections:** Osteomyelitis, urethritis, gonorrhoea, syphilis, lymphogranuloma venereum, diphtheria, prostatitis, scarlet fever.

Note: The antibiotic has also proved to be of value in endocarditis and septicaemia, but in these conditions initial administration of erythromycin lactobionate by the intravenous route is advisable.

Microbiological indications: Erythrocin is active against a wide variety of pathogenic organisms, Gram-positive cocci – staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, *Corynebacterium diphtheriae* (as an adjunct to antitoxin), neisseria, *Treponema pallidum*, bordetella.

Note: The majority of strains of *Haemophilus influenzae* are susceptible to the concentrations reached after ordinary doses.

Dosage and administration **Adults:** 1–2 g per day divided into 6, 8 or 12 hourly doses. May be increased up to 4 g daily in severe infections.

The usual adult dose is one 250 mg tablet four times a day, or twice daily dosage can be given if preferred. Tablets should be taken before or with meals.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to erythromycin.

Precautions: Erythromycin is excreted principally by the liver, so caution should be exercised in administering the antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy. It has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Side-effects and precautions: There are very few side-effects to any Abbott Erythrocin product. There are no reports implicating Erythrocin with abnormal tooth development and only rare reports of damage to the blood, kidneys, liver or central nervous system. Allergic reactions are rare and mild, although anaphylaxis has occurred. Occasionally there is abdominal discomfort after oral administration, sometimes with nausea and vomiting. It usually subsides after a few days without having to reduce the dosage. The rare possibility of superinfection caused by overgrowth of non-susceptible bacteria or fungi should be kept in mind during prolonged or repeated therapy, especially when other antibacterial agents are simultaneously employed.

Overdosage: **Symptoms:** nausea, vomiting, diarrhoea.

Treatment: Gastric lavage, general supportive measures.

Pharmaceutical precautions Protect Filmtabs from light. Store below 25°C.

Legal category POM.

Package quantities Erythrocin 250 mg is supplied in containers of 100, 500 and 1,000 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.07 g per tablet.

Product licence number 0037/5079.

ERYTHROCIN® 500

Presentation Each white Erythrocin 500 Filmtab® (film-coated tablet Abbott) contains 500 mg erythromycin activity as Erythromycin Stearate BP.

Uses For the prophylaxis and treatment of infections caused by erythromycin-sensitive organisms.

Clinical indications: Erythrocin is highly effective in the treatment of a great variety of clinical infections.

1. **Upper respiratory tract infections:** Tonsillitis, peritonsillar abscess, pharyngitis, laryngitis, sinusitis, secondary infections in colds and influenza.
2. **Lower respiratory tract infections:** Tracheitis, acute and chronic bronchitis, pneumonia (lobar pneumonia, bronchopneumonia, primary atypical pneumonia), bronchiectasis, legionnaires' disease.
3. **Ear infections:** Otitis media and otitis externa, mastoiditis.
4. **Oral infections:** Gingivitis, Vincent's angina.
5. **Eye infections:** Blepharitis.
6. **Skin and soft-tissue infections:** Boils and carbuncles, paronychia, abscesses, pustular acne, impetigo, cellulitis, erysipelas.

7. *Gastro-intestinal infections*: Cholecystitis, staphylococcal enterocolitis.

8. *Prophylaxis*: Pre- and post-operative, trauma, burns, rheumatic fever.

9. *Other infections*: Osteomyelitis, urethritis, gonorrhoea, syphilis, lymphogranuloma venereum, diphtheria, prostatitis, scarlet fever.

Note: The antibiotic has also proved to be of value in endocarditis and septicaemia, but in these conditions initial administration of erythromycin lactobionate by the intravenous route is advisable.

Microbiological indications: Erythrocin is active against a wide variety of pathogenic organisms, Gram-positive cocci – staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, *Corynebacterium diphtheriae* (as an adjunct to antitoxin), neisseria, *Treponema pallidum*, bordetella.

Note: the majority of strains of *Haemophilus influenzae* are susceptible to the concentrations reached after ordinary doses.

Dosage and administration Adults 1–2 g daily, divided into 6, 8 or 12 hourly doses. May be increased up to 4 g daily in severe infections.

Tablets should be taken before or with meals.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to erythromycin.

Precautions: Erythromycin is excreted principally by the liver, so caution should be exercised in administering the antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy and it has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Overdosage: *Symptoms*: nausea, vomiting, diarrhoea.

Treatment: Gastric lavage, general supportive measures.

Pharmaceutical precautions Protect Filmtabs from light. Store below 25°C.

Legal category POM.

Package quantities Erythrocin 500 is supplied in blister packs of 15 and containers of 100 and 500 tablets.

Further information *Metabolisable carbohydrate content*: Approx. 0.15 g per tablet.

Product licence number 0037/5044.

ERYTHROCIN* I.V. LACTOBIONATE

Presentation Erythrocin I.V. Lactobionate is a soluble erythromycin salt suitable for intravenous administration. It is in the form of a sterile, lyophilised powder for reconstitution, in vials containing 300 mg erythromycin activity as the lactobionate, and in vials containing 1 g erythromycin activity as the lactobionate. When reconstituted according to the directions the concentration of benzyl alcohol (as a preservative) in the 5% stock solution is 0.9% in both strengths.

Uses *Clinical indications*: Erythrocin is highly effective in the treatment of a great variety of clinical infections. It is indicated in severe cases of infection caused by sensitive organisms and in cases where high blood levels are required at the earliest opportunity, or when the oral route is not available.

1. Upper respiratory tract infections.
2. Lower respiratory tract infections.
3. Skin and soft-tissue infections.
4. Gastro-intestinal infections.
5. Prophylaxis: Pre- and post-operative, trauma, burns and rheumatic fever.
6. Endocarditis and septicaemia.

Microbiological indications: Erythrocin is active against a wide variety of pathogenic organisms, Gram-positive cocci-staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, *Corynebacterium diphtheriae* (as an adjunct to antitoxin), neisseria, *Treponema pallidum*, bordetella.

Adults: Mild to moderate infections: 2 grams daily in divided doses.

Severe infections: 4 grams or more daily in divided doses.

Children: Mild to moderate infections: 30 mg/kg body weight daily in divided doses.

Severe infections: 50 mg/kg body weight daily in divided doses.

Administration: This may be by continuous infusion or by intermittent intravenous injection. The preparation is not suitable for intramuscular use.

For continuous infusion a concentration of 1 mg erythromycin per ml is recommended at final dilution.

For intermittent injection a concentration of 1 to 5 mg erythromycin per ml is recommended. This should be administered at intervals of not more than 6 hours. Injection should be sufficiently slow to avoid pain along the vein (several minutes if necessary).

Preparation of Solution:

1. Preparation of a 5% stock solution. (a) 300 mg vial: Add 6 ml of Water for Injections BP to the vial to obtain a stock solution containing 50 mg erythromycin per ml (5% solution). (b) 1 g vial: Add 20 ml of Water for Injections BP to the vial to obtain a stock solution containing 50 mg erythromycin per ml (5% solution).

Do not use 0.9% w/v Saline or other electrolyte solutions as, at this concentration, a precipitate may form.

Use within 24 hours of reconstitution.

2. Further dilution. The 1 mg erythromycin/ml (0.1% solution) is obtained by diluting the stock solution to 50 times its original volume. Thus, for the 300 mg vial from 6 ml to 300 ml, for the 1 g vial from 20 ml to 1,000 ml.

The 5 mg erythromycin/ml (0.5% solution) is obtained by diluting the stock solution to 10 times its original volume. Thus, for the 300 mg vial from 6 ml to 60 ml, for the 1 g vial from 20 ml to 200 ml.

The following are suitable diluents: Sodium Chloride Injection BP (0.9% saline), Compound Sodium Lactate Injection BP (Hartmann's Solution).

Solutions containing dextrose may also be used but sodium bicarbonate must first be added as a buffer to ensure neutrality.

2.4 ml of sterile 8.4% w/v sodium bicarbonate solution will neutralise one litre each of: Dextrose Injection BP (5%), or of Sodium Chloride and Dextrose Injection BP (usually 0.18% sodium chloride and 4.0% dextrose).

The stability of solutions of Erythrocin Lactobionate is adversely affected below pH 5.5.

To ensure potency, solutions of Erythrocin Lactobionate at final dilution should be administered completely within 8 hours of preparation.

Contra-indications, warnings, etc

Contra-indications: Compatibility with other I.V. additives has not been established. Known sensitivity to erythromycin.

Precautions: Extravasation should be avoided. The injection should be slow (several minutes if necessary) to avoid pain along the vein.

Erythromycin is excreted principally by the liver, so caution should be exercised in administering the antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Reversible hearing loss associated with the intravenous infusion of 4 or more grams per day of erythromycin lactobionate has been reported rarely.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy and it has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Side-effects: There are very few side-effects to any Abbott Erythrocin product. There are no reports implicating Erythrocin with abnormal tooth development and only rare reports of damage to the blood, kidneys, liver or central nervous system. Allergic reactions are rare and mild, although anaphylaxis has occurred. The rare possibility of superinfection caused by overgrowth of non-susceptible bacteria or fungi should be kept in mind during prolonged or repeated therapy, especially when other antibacterial agents are simultaneously employed.

Pharmaceutical precautions The powder is stable at room temperature. Use within 24 hours of reconstitution.

Legal category POM.

Package quantities Erythrocin I.V. Lactobionate is supplied in 300 mg vials and in 1 g vials.

Further information Contains no sodium.

ERYTHROCIN* ORAL SUSPENSION

Presentation A ready-made caramel-flavoured suspension containing 100 mg erythromycin activity per 5 ml as erythromycin stearate.

Uses For the prophylaxis and treatment of infections caused by erythromycin-sensitive organisms.

Clinical indications: Erythrocin is highly effective in the treatment of a great variety of clinical infections.

1. Upper respiratory tract infections: Tonsillitis, peritonsillar abscess, pharyngitis, laryngitis, sinusitis, secondary infections in colds and influenza.

2. Lower respiratory tract infections: Tracheitis, acute and chronic bronchitis, pneumonia (lobar pneumonia, bronchopneumonia, primary atypical pneumonia), bronchiectasis, legionnaires' disease.

3. Ear infections: Otitis media and otitis externa, mastoiditis.

4. Oral infections: Gingivitis, Vincent's angina.

5. Eye infections: Blepharitis.

6. Skin and soft-tissue infections: Boils and carbuncles, paronychia, abscesses, pustular acne, impetigo, cellulitis, erysipelas.

7. Gastro-intestinal infections: Cholecystitis, staphylococcal enterocolitis.

8. Prophylaxis: Pre- and post-operative, trauma, burns, rheumatic fever.

9. Other infections: Osteomyelitis, urethritis, gonorrhoea, syphilis, lymphogranuloma venereum, diphtheria, prostatitis, scarlet fever.

Note: The antibiotic has also proved to be of value in endocarditis and septicaemia, but in these conditions initial administration of erythromycin by the intravenous route is advisable.

Microbiological indications: Erythrocin is active against a wide variety of pathogenic organisms, Gram-positive cocci – staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, *Corynebacterium diphtheriae* (as an adjunct to antitoxin), neisseria, *Treponema pallidum*, bordetella.

Note: The majority of strains of *Haemophilus influenzae* are susceptible to the concentrations reached after ordinary doses.

Dosage and administration 30–50 mg/kg per day divided into 6-, 8- or 12-hourly doses. For very severe infections the dosage may be increased to 4 g or more per day for adults.

Note: Shake the suspension well before using.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to erythromycin.

Precautions: Erythromycin is excreted principally by the liver, so caution should be exercised in administering the

antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy and it has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Side-effects and precautions: There are very few side-effects to any Abbott Erythrocin product. There are no reports implicating Erythrocin with abnormal tooth development, and only rare reports of damage to the blood, kidneys, liver or central nervous system. Allergic reactions are rare and mild although anaphylaxis has occurred. Occasionally there is abdominal discomfort after oral administration, sometimes with nausea and vomiting. It usually subsides after a few days without having to reduce the dosage. The rare possibility of super-infection caused by overgrowth of non-susceptible bacteria or fungi should be kept in mind during prolonged or repeated therapy, especially when other antibacterial agents are simultaneously employed.

Overdosage: Symptoms: nausea, vomiting and diarrhoea.

Treatment: Gastric lavage, general supportive measures.

Pharmaceutical precautions Protect from heat. Store below 30°C.

Legal category POM.

Package quantities Erythrocin Suspension is supplied in bottles of 100 and 500 ml.

Further information Metabolisable carbohydrate content: approximately 3.5 g per 5 ml.

Product licence number 0037/5045.

ERYTHROPEP* PI ERYTHROPEP* ERYTHROPEP* FORTE

Presentation Erythromycin ethyl succinate in the form of granules which, when reconstituted, make a cherry-flavoured suspension. It is available in three strengths:

- 1) Erythropep PI which contains 125 mg erythromycin activity per 5 ml.
- 2) Erythropep containing 250 mg erythromycin activity per 5 ml.
- 3) Erythropep Forte containing 500 mg erythromycin activity per 5 ml.

In addition, Erythropep PI is available in single dose sachets each containing 125 mg erythromycin activity. Erythropep is available in single dose sachets each containing 250 mg erythromycin activity.

Uses Clinical indications: Erythropep is highly effective in the treatment of a great variety of clinical infections:

1. **Upper respiratory tract infections:** Tonsillitis, peritonsillar abscess, pharyngitis, laryngitis, sinusitis, secondary infections in colds and influenza.

2. **Lower respiratory tract infections:** Tracheitis, acute and chronic bronchitis, pneumonia (lobar pneumonia, bronchopneumonia, primary atypical pneumonia), bronchiectasis, legionnaires' disease.

3. **Ear infections:** Otitis media and otitis externa, mastoiditis.

4. **Oral infections:** Gingivitis, Vincent's angina.

5. **Eye infections:** Blepharitis.

6. **Skin and soft-tissue infections:** Boils and carbuncles, paronychia, abscesses, pustular acne, impetigo, cellulitis, erysipelas.

7. **Prophylaxis:** Pre- and post-operative, trauma, burns, rheumatic fever.

8. **Genito-urinary infections:** Urethritis, gonorrhoea, syphilis, lymphogranuloma venereum, prostatitis.

9. **Other infections:** Osteomyelitis, diphtheria, scarlet fever.

Note: The antibiotic has also proved to be of value in endocarditis and septicaemia, but in these conditions initial administration of erythromycin lactobionate by the intravenous route may be advisable.

Microbiological indications: Erythropep is active against a wide variety of pathogenic organisms, Gram-positive cocci – staphylococci, pneumococci and streptococci (including enterococci) – meningococci, mycoplasma, L-forms, *Haemophilus influenzae*, the agents causing trachoma and lymphogranuloma venereum, chlamydia, clostridia, corynebacteria, neisseria, *Treponema pallidum*, bordetella.

Note: The majority of strains of *Haemophilus influenzae* are susceptible to the concentrations reached after ordinary doses.

Dosage and administration Reconstitution: Erythropep products are taken orally after being reconstituted as follows:

1. **Erythropep PI:** Add 69 ml water to the granules contained in 100 ml bottle and shake vigorously. This will make 100 ml of the suspension, each 5 ml containing 125 mg erythromycin activity.
2. **Erythropep:** Add 68 ml water to the granules contained in 100 ml bottle and shake vigorously. This will make 100 ml of the suspension, each 5 ml containing 250 mg erythromycin activity.
3. **Erythropep Forte:** Add 61 ml water to the granules contained in 100 ml bottle and shake vigorously. This will make 100 ml of the suspension, each 5 ml containing 500 mg erythromycin activity.
4. **Erythropep PI single dose sachet.** Disperse the contents of the sachet in a little water before taking.
5. **Erythropep single dose sachet:** Disperse the contents of the sachet in a little water before taking.

Recommended dosage:

1. Erythropep PI suspension and single dose sachets for infants and babies up to 2 years of age, 125 mg, four times daily.

2. Erythropep suspension and single dose sachets for children between the ages of 2 and 8 years, 250 mg, four times daily.

3. Erythropep Forte for children above 8 years of age, and adults, 500 mg, four times daily.

When twice daily medication is required for children over 2 years of age, half the total dose may be given every 12 hours.

In terms of mg/kg the usual dose is 30 mg erythromycin/kg/day in divided doses. In very severe infections

this may be increased to 50 mg erythromycin/kg/day in divided doses.

The usual adult dose is 2 g/day in divided doses. For severe infections this may be increased to 4 g or more, per day, in divided doses.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to erythromycin.

Precautions: Erythroped is excreted principally by the liver, so caution should be exercised in administering the antibiotic to patients with impaired hepatic function or concomitantly receiving potentially hepatotoxic agents.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Use in pregnancy: There is no evidence of hazard from erythromycin in human pregnancy and it has been in wide use for many years without apparent ill consequence. Animal studies have shown no hazard.

Side-effects: There are very few side-effects to any Abbott Erythroped product. There are no reports implicating Erythroped with abnormal tooth development and only rare reports of damage to the blood, kidneys, liver or central nervous system. Allergic reactions are rare and mild, although anaphylaxis has occurred. Occasionally there is abdominal discomfort after oral administration, sometimes with nausea and vomiting. It usually subsides after a few days without having to reduce the dosage.

Overdosage: *Symptoms:* nausea, vomiting and diarrhoea.

Treatment: Gastric lavage, general supportive measures.

Pharmaceutical precautions Store in a cool place and keep the container tightly closed. The suspension should be used within 5 days after reconstitution. Shake well before using.

Legal category POM.

Package quantities Erythroped PI is supplied in 100 ml bottles, and in boxes of 200 single dose sachets. Erythroped is supplied in 100 ml bottles, and in boxes of 200 single dose sachets. Erythroped Forte is supplied in 100 ml bottles.

Further information *Metabolisable carbohydrate content:* Erythroped PI, approx. 2.0 g per 5 ml or 0.9 g per sachet.

Erythroped approx. 1.9 g per 5 ml or per sachet.

Erythroped Forte, approx. 2.0 g per 5 ml.

ETHRANE* ▼

Presentation Ethrane (enflurane) is an inhalation anaesthetic with a pleasant ethereal odour. No additives or stabilisers are present.

Actions Induction and recovery are rapid. It does not stimulate excessive salivation, tracheobronchial secretions or cause bronchial constriction. Pharyngeal and laryngeal reflexes are diminished quickly. The level of anaesthesia changes rapidly with Ethrane. Tachypnoea does not usually occur. Spontaneous respiration becomes depressed as the depth of anaesthesia increases.

Ethrane provokes a 'sigh' response reminiscent of that seen with diethyl ether.

During induction there is a decrease in blood pressure followed by a return to near normal levels, which may or may not be associated with surgical stimulation.

Blood pressure tends to fall in direct relation to the depth of anaesthesia but cardiac rate and rhythm remain stable. Ethrane appears to 'sensitise' the myocardium to adrenaline in man to a lesser extent than halothane. Available data indicate that subcutaneous injections of adrenaline may be safely administered to humans in concentrations of 1:100,000 or less at a dose of 10 ml in any given 10 minute period and not more than 30 ml/hour. All the usual precautions in the use of vasoconstrictor substances must be observed.

Good muscular relaxation is obtained with Ethrane, but should greater relaxation be necessary minimal doses of an intravenous muscle relaxant may be used with measures to ensure adequate ventilation.

All commonly used intravenous muscle relaxants are compatible with Ethrane.

Note: Ethrane potentiates the effect of the non-depolarising muscle relaxants which should therefore be used in reduced dosage. Neostigmine does not reverse the direct effect of Ethrane.

Ethrane produces little post operative analgesia.

Ethrane may be used for induction and maintenance of general anaesthesia. Adequate data are not available yet to establish its full place in obstetric anaesthesia other than in caesarean section. High concentrations of Ethrane may produce marked uterine relaxation.

Ethrane may be used for outpatient and dental anaesthesia in view of the rapidity of action and recovery, with stability of the cardiovascular system. Ethrane can be used safely in children.

Metabolism of Ethrane in the human body proceeds at a low rate; inorganic fluoride is formed but serum levels in healthy individuals have not been shown to rise to significant levels.

Dosage and administration Vaporisers calibrated specifically for Ethrane should be used so that the concentration being delivered is known.

Premedication: Drugs used for premedication should be selected for each individual patient. The use of anticholinergic drugs is a matter of choice.

Induction: To avoid excitement a short-acting barbiturate or other intravenous induction agent should be administered, followed by inhalation of the Ethrane mixture. Ethrane and oxygen alone or oxygen-nitrous oxide mixtures may be used.

It is recommended that Ethrane induction be initiated at a concentration of 0.4% and gradually increased by 0.5% increments after every few breaths until surgical anaesthesia is achieved.

The maximum inspired concentrations during induction should be no more than 4.5%. High inspired concentrations should be lowered as rapidly as possible to maintenance levels to prevent overdosage, and the blood pressure carefully observed.

Maintenance: In conjunction with nitrous oxide, surgical

levels of anaesthesia may be maintained with a 0.5%–3% concentration of Éthane. A 3% concentration should not be exceeded for maintenance during spontaneous respiration. With controlled respiration techniques, during prolonged operations, single or supplementary doses of muscle relaxants may be used if required, bearing in mind the possibility of some slight potentiation. Ventilation to maintain the carbon dioxide tension in arterial blood in the 4.7–6.0 kPa (35–45 mmHg) range is preferred to hyper- or hypoventilation, in order to minimise the possibility of CNS excitation.

Blood pressure levels during maintenance depend on Éthane concentration in the absence of other complicating factors. Excessive decreases (unless related to hypovolaemia) may be due to depth of anaesthesia and in such instances should be corrected by reducing the inspired Éthane concentration.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to Éthane.

Precautions: Éthane should be used with caution in patients who by virtue of medical or drug history, may be considered more susceptible to cerebral stimulation produced by this drug. Increasing depth of anaesthesia with Éthane may produce changes in the electroencephalogram characterised by high voltage, fast frequency waves progressing through spike-dome complexes alternating with periods of electrical silence to frank seizure activity patterns. The latter may or may not be associated with motor movement. Motor activity, when encountered, generally consists of twitching or 'jerks' of various muscle groups; it is self-limiting and can be terminated by lowering the anaesthetic concentration. This electroencephalographic pattern associated with deep anaesthesia may be exacerbated by hyperventilation producing low arterial carbon dioxide tension. The pattern serves as a warning that depth of anaesthesia is excessive. Cerebral blood flow and metabolism studies in normal volunteers during seizure patterns show no evidence of cerebral hypoxia, and recovery appears to be uncomplicated.

Since levels of anaesthesia may be altered easily and rapidly, only vaporisers which deliver a predictable output with reasonable accuracy should be used. Hypotension and respiratory exchange can serve as a guide to anaesthetic depth. With deep levels of anaesthesia, more marked hypotension and respiratory depression are encountered.

The action of non-depolarising relaxants is augmented by Éthane, so less than the usual amounts of those drugs should be used.

Overdosage or unduly rapid absorption of adrenaline administered topically or by subcutaneous or submucosal injection during Éthane anaesthesia may give rise to cardiac arrhythmias (see 'Actions' section). Care must be taken to avoid intravenous injection.

Bromsulphthalein (BSP) retention is mildly raised post-operatively in some cases. There is some elevation of blood glucose and white blood cell count intra-operatively.

Use in pregnancy: Reproduction studies have been performed in rats and rabbits. Following single and multiple maternal administrations, no evidence of teratogenicity due to Éthane was found in the developing fetuses in these species. The relevance of these studies to the human is not known. Since there is no adequate experience in pregnant women who have received the drug, safety in pregnancy has not been established.

Adverse reactions:

1. Motor activity exemplified by movement of various muscle groups and seizures may be encountered with deep levels of Éthane anaesthesia, particularly with hyperventilation.

2. Hypotension, respiratory depression and arrhythmias have been reported.

3. Elevation of the white blood cell count has been observed. It has not been determined whether this is related to Éthane or to surgical stress.

4. A mild increase in serum glucose concentration has been observed in some normal and diabetic patients, as with other anaesthetic agents. There seems to be no contra-indication to the use of the agent in these patients for whom rapid recovery is advantageous.

5. Hepatic enzyme changes occur less frequently and to a lesser degree after multiple Éthane anaesthetics when compared with multiple exposures to halothane. While jaundice and significant hepatic enzyme increases occasionally occur after halothane anaesthesia there is, as yet, no report of their appearance after the administration of Éthane in the absence of complicating factors such as blood transfusion or concomitant administration of hepatotoxic drugs.

6. Increased serum inorganic fluoride levels have been found during and immediately after Éthane anaesthesia due to biodegradation of the agent. These levels normally remain well below the postulated threshold for nephrotoxicity and, after reaching a peak within eight hours of the end of the anaesthetic, rapidly return to preoperative values.

Although there is no evidence that Éthane anaesthesia adversely affects the normal or diseased kidney it may be prudent to avoid its use in cases of chronic renal failure.

Side-effects: Nausea, vomiting, hiccups or shivering may occur occasionally.

Pharmaceutical precautions Store away from heat. Keep well closed.

Legal category P.

Package quantities Éthane is supplied in bottles of 250 ml.

Further information Nil.

Product licence number 0037/0053.

EUTONYL*

Presentation Each apricot Eutonyl Filmtab* (film-coated tablet Abbott) contains 25 mg pargyline hydrochloride.

Uses For the treatment of resistant hypertension, particularly when other treatments have failed.

Note: Eutonyl is a monoamine oxidase inhibitor and the usual precautions necessary with this class of drug must be observed.

Dosage and administration Eutonyl is administered orally as a single daily dose; there is no known advantage in prescribing the drug more frequently. Clinical response to the drug is not immediate. Four days to three weeks or more may be required to produce the full effects of a given daily dosage. For this reason it is generally unwise to increase dosage more frequently than once a week. The effects of the drug may persist following reduction of dosage or withdrawal. If therapy must be interrupted

because of undesirable side-effects, the drug should be withheld until all such effects have disappeared. Therapy is then reinstituted at a lower dosage. Because the drug exerts an orthostatic effect on blood pressure, dosage adjustments should be based upon the blood pressure response in the standing position.

The usual adult dosage for initiating therapy in hypertensive patients not receiving other antihypertensive agents is 25 mg once daily. This dosage may be increased once a week until the desired response is obtained, or a maximum of 75 mg per day is reached. Patients over the age of 65, or those who have undergone sympathectomy, may be unusually sensitive to the antihypertensive properties of the drug. When Eutonyl is added to an established antihypertensive regimen, the initial dose should not exceed 25 mg daily (less in sympathectomised or elderly patients).

Eutonyl should not be administered to children under 12 years of age, because of limited experience with this group.

Reduction of blood pressure is often maintained in hypertensive patients with a daily dose of 25–50 mg of Eutonyl alone. Larger doses may be tried in resistant cases. In general, the dosage should be kept at the minimum level required to maintain a desirable reduction in blood pressure without encountering undue side-effects. A few patients may develop a relative tolerance to the antihypertensive effects of the drug.

Contra-indications, warnings, etc

Contra-indications: Phaeochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Eutonyl should not be administered to pregnant patients, those with malignant hypertension, or to children under 12 years of age because significant clinical information concerning the use of the drug in these conditions is not available. In general the following drugs or agents are contra-indicated in patients receiving Eutonyl:

Centrally acting sympathomimetic amines such as amphetamine and its derivatives (also found in anorectic preparations).

Some patients may experience a mood-elevating effect, as may happen with many compounds of this class. However, clinical studies have not clearly differentiated the mood-elevating effects from those which may result from the reduction of blood pressure alone.

Peripherally acting sympathomimetic drugs such as ephedrine and its derivatives (also found in nasal decongestants, cold remedies and hay-fever preparations).

Aged cheese (e.g. Cheddar, Camembert, and Stilton), processed cheese and other foods which require the action of bacteria or moulds for their preparation or preservation (e.g. Chianti wine) because of the presence of pressor substances such as tyramine. Other foods which should be avoided during pargyline therapy because of their high pressor amine content include chocolate, yeast extract, avocado, pickled herring, pods of broad beans, banana peels and chicken livers. Cream cheese and cottage cheese can be allowed in the diet during pargyline therapy since their tyramine content is low.

In some patients receiving pargyline, tyramine may precipitate an abrupt rise in blood pressure accompanied by some or all of the following: severe headache, chest pain, profuse sweating, palpitation, tachycardia or bradycardia, visual disturbances, stertorous breathing, coma and intracranial bleeding (which could be fatal). A

phenothiazine derivative or phentolamine may be administered parenterally for treatment of such an acute hypertensive reaction.

Parenteral administration of reserpine or guanethidine which may cause hypertensive reactions from sudden release of catecholamines. Parenteral use of these drugs is contra-indicated during, and for at least one week following, treatment with pargyline hydrochloride.

Imipramine, amitriptyline, desipramine, nortriptyline or their analogues should not be used with pargyline. The use of these drugs with a monoamine oxidase inhibitor has been reported to cause vascular collapse and hyperthermia which may be fatal. A drug-free interval (at least two weeks) should separate therapy with Eutonyl and use of these agents.

Other monoamine oxidase inhibitors, since they may augment the effects of pargyline hydrochloride.

Methyldopa or dopamine, which may cause hyperexcitability in patients receiving pargyline hydrochloride.

There have been several reports of potentiation of the pressor effects of L-dopa by various monoamine oxidase inhibitors. For this reason concomitant therapy is contra-indicated and at least one month should elapse after discontinuation of a monoamine oxidase inhibitor before L-dopa is given.

Patients' warnings:

1. Patients should be warned against the use of any over-the-counter preparations, particularly 'cold preparations' and antihistamines, or prescription drugs without the knowledge and consent of the physician.

2. Patients should be cautioned on the use of cheese (see contra-indications) and alcoholic beverages in any form.

3. Patients should be warned about the likelihood of the occurrence of orthostatic hypotension.

4. Patients should be instructed to report promptly the occurrence of severe headache or other unusual symptoms.

5. Patients with angina pectoris or coronary artery disease should be especially warned not to increase their physical activities in response to a diminution in anginal symptoms or an increase in well-being occurring during treatment with Eutonyl.

Physicians' warnings:

1. When indicated the following should be cautiously prescribed in reduced dosages: antihistamines; hypnotics, sedatives or tranquillisers; narcotics (pethidine should not be used).

2. Discontinue Eutonyl at least two weeks prior to elective surgery.

3. In emergency surgery the dose of narcotics or other premedication should be reduced to one quarter or one-fifth of the usual amount. Clinical experience has shown that response to all anaesthetic agents can be exaggerated in patients receiving Eutonyl. Therefore the dose of the anaesthetic should be carefully adjusted.

4. Eutonyl may induce hypoglycaemia.

5. Care should be exercised in using Eutonyl in patients with advanced renal failure.

Precautions: The therapeutic response to a variety of drugs may be changed or exaggerated in patients receiving a monoamine oxidase inhibitor such as pargyline hydrochloride. Alcohol, narcotics (pethidine should be avoided), antihistamines, anaesthetics, barbiturates, chloral hydrate and other hypnotics, sedatives, tranquillisers or caffeine should be used cautiously and at a reduced dosage in patients who are taking Eutonyl.

An increased response to central depressants may be

manifested by acute hypotension and increased sedative effect. Pargyline hydrochloride may increase the hypotensive effects of anaesthetic agents and surgery, and so should be discontinued for 10–14 days prior to surgery. In the event of emergency surgery, smaller doses than usual (one-quarter to one-fifth) of narcotics, analgesics and other premedications should be used. If severe hypotension should occur, this can be controlled by small doses of a vasopressor agent such as noradrenaline.

Febrile illnesses may increase the hypotensive effect and it may be advisable to withdraw the drug during such diseases. Eutonyl is a non-hydrazine derivative and has not been shown to damage the kidney, liver or blood-forming organs, or to be associated with optic atrophy. However, laboratory studies including urinalyses, liver function tests and complete blood counts should be performed periodically. The drug should be used with caution in the presence of liver disease. Since pargyline hydrochloride is excreted primarily in the urine, patients with impaired renal function may experience cumulative drug effects. Such patients should also be watched for elevations of blood urea nitrogen and other evidence of progressive renal failure. If such alterations should persist and progress, the drug should be discontinued.

Patients receiving this drug for prolonged periods of time should be examined for any changes in colour perception, visual fields, fundi and visual acuity.

Patients with angina pectoris or coronary artery disease should be warned against an increase in physical activity because of the diminution of anginal symptoms and an increased feeling of well-being with Eutonyl. All patients should be warned about the possible occurrence of orthostatic hypotension. If hypotension develops in these patients, Eutonyl dosage should be reduced or therapy discontinued since severe and/or prolonged hypotension may precipitate cerebral or coronary vessel thrombosis.

Eutonyl should not be used in individuals with hyperactive or hyperexcitable personalities, as some of these patients show an undesirable increase in motor activity with restlessness, confusion, agitation and disorientation.

Clinical studies have shown that pargyline may unmask severe psychotic symptoms such as hallucinations or paranoid delusions in some patients with pre-existing serious emotional problems. This can usually be controlled by judicious administration of chlorpromazine intramuscularly or other phenothiazines, the patient remaining supine for one hour after administration. Pargyline hydrochloride should be used with caution in patients with parkinsonism as it may increase symptoms. In addition great care is required if pargyline hydrochloride is administered in conjunction with anti-parkinsonian agents. Clinical reports state that certain individuals receiving pargyline hydrochloride for a prolonged period of time are refractory to the nerve-blocking effects of local anaesthetics.

Side-effects: Apart from hypotensive symptoms due to overdosage, the side-effects with Eutonyl are relatively infrequent especially if the dosage is kept as low as possible by combining it with a thiazide. Apart from orthostatic hypotension, side-effects include mild constipation, oedema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence and delayed ejaculation, rash and purpura. Gain in weight may be due to either oedema or increased

appetite. Drug fever is extremely rare. In some patients a reduction of the blood sugar has been noted. Congestive heart failure has been reported in patients with reduced cardiac reserve. Muscular twitching and extrapyramidal-like symptoms have also been reported.

Overdosage: Symptoms: Reported effects of monoamine oxidase inhibitor overdosage include agitation, hallucinations and exaggerated reflexes, hyperpyrexia, convulsions and both hypotension and hypertension.

Treatment: Management must be attempted with great caution because of the possibility of interaction with the drugs used. Conservative treatment to maintain normal temperature, respiration, blood pressure and correct fluid and electrolyte balance is usually successful.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Eutonyl is supplied in containers of 100 Filmtabs.

Further information *Metabolisable carbohydrate content:* approx 0.11 g per tablet.

Product licence number 0037/5032.

FERRO-GRADUMET*

Presentation Each red Filmtab* (film-coated tablet Abbott) contains Dried Ferrous Sulphate BP 325 mg (equivalent to 105 mg elemental iron) in a sustained release form (Gradumet*).

Uses For the prevention and treatment of iron-deficiency anaemia.

The Gradumet device allows sustained release of the active ingredient over a number of hours, which increases iron utilisation and reduces gastro-intestinal intolerance.

The device consists of an inert plastic matrix, honey-combed by thousands of narrow passages which contain the active drug together with a water-soluble channelling agent. As the tablet passes down the gastro-intestinal tract the iron is leached out. The spent matrix is finally excreted in the stools.

Dosage and administration *Recommended adult oral dosage:* 1 tablet daily before food. As gastro-intestinal intolerance is not a problem with Ferro-Gradumet it should be given on an empty stomach, when iron is most effectively absorbed.

Children: Not suitable for children under 12 years of age.

Contra-indications, warnings, etc *Precautions:* As with all iron preparations Ferro-Gradumet should be given with care in patients with haemochromatosis, haemolytic anaemia or haemoglobinopathies. Interaction (chelation) with tetracyclines. Ferro-Gradumet tablets should be kept out of children's reach.

Side-effects: Those associated with conventional oral iron preparations, such as nausea, vomiting, diarrhoea and/or constipation, are less likely to occur. Because of the sustained release pattern, only a small amount of the iron is released in the stomach which is never exposed to large amounts of iron as is the case with ordinary tablets. The clinical advantages which follow are twofold – minimal side-effects and efficient absorption.

Overdosage: Symptoms: The initial symptoms of massive ferrous sulphate overdosage are absent, the delayed release allowing sufficient time for gastric lavage and

other forms of treatment to be effective before absorption occurs to any extent. Treatment should not be delayed, therefore, even if immediate symptoms are absent. Symptoms may include gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Treatment: The ingested Gradumet matrix cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the Gradumet without harming the gastric mucosa. Accordingly, when overdosage is discovered early, the following procedure is recommended.

1. Administer an emetic by stomach tube.
2. Withdraw the stomach tube and wait for the patient to vomit.
3. Keep the patient under constant surveillance to detect possible aspiration of vomitus; maintain suction apparatus and standby emergency oxygen in case of need.
4. Examine the vomitus for returned Gradumet tablets.
5. Administer a saline cathartic. By the time toxic signs have appeared, Gradumet tablets are in most cases past the pylorus so that emesis is of no value. Gastric lavage may be considered to remove amounts of the drug already released in the stomach. A saline cathartic then should be given to speed the Gradumet tablets along the alimentary canal so as to minimise or prevent further absorption of the medication.
6. The use of an iron chelating agent such as oral desferrioxamine should be considered. In severe cases parenteral desferrioxamine may be necessary.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Ferro-Gradumet is supplied in 5 carton packs, each carton containing 30 (2 × 15) tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.02 g per tablet.

Product licence number 0037/5000.

FERROGRAD® C

Presentation Each two-layered, red Filmtab® (film-coated tablet Abbott) contains Dried Ferrous Sulphate BP 325 mg (equivalent to 105 mg elemental iron) in a sustained release form (Gradumet®) and 500 mg vitamin C, as sodium ascorbate.

Uses For the prevention and treatment of iron-deficiency anaemia and for the simultaneous treatment of vitamin C deficiency.

The Gradumet device allows sustained release of ferrous sulphate over a number of hours, which increases iron utilisation and reduces gastro-intestinal intolerance. The Gradumet consists of an inert plastic matrix honey-combed by thousands of narrow passages which contain the active drug together with a water-soluble channelling agent. As the tablet passes down the gastro-intestinal tract the iron is leached out. The spent matrix is finally excreted in the stools.

Ferrograd C combines the advantages of ferrous sulphate in the Gradumet matrix with a large dose of vitamin C further to enhance absorption and is indicated in iron-deficiency anaemia, especially when poor ab-

sorption is a problem, and to promote haemopoiesis in patients where an underlying Vitamin C deficiency limits optimal haemoglobin formation. In patients whose haemoglobin has returned to normal, Ferrograd C may be of particular value in replenishing the depleted stores of iron.

Dosage and administration *Recommended adult oral dosage:* 1 tablet a day before food.

Children: not recommended for children under 12 years of age.

Contra-indications, warnings, etc *Warning:* The administration of therapeutic doses of ascorbic acid may interfere with the Clinistix test for glycosuria giving a false negative result.

Side-effects: Those associated with conventional oral iron preparations, such as nausea, vomiting, diarrhoea and/or constipation, are less likely to occur. Because of the sustained release pattern only a small amount of the iron is released in the stomach, which is never exposed to large amounts of iron as is the case with ordinary tablets. The clinical advantages which follow are two-fold – minimal side-effects and efficient absorption.

Precautions: As with all iron preparations Ferrograd C should be given with care in patients with haemochromatosis, haemolytic anaemias or haemoglobinopathies. Interaction (chelation) with tetracyclines. Ferrograd C Tablets should be kept out of children's reach.

Overdosage: Symptoms: The initial symptoms of massive ferrous sulphate overdosage are absent, the delayed release allowing sufficient time for gastric lavage and other forms of treatment to be effective before absorption occurs to any extent. Treatment should not be delayed, therefore, even if immediate symptoms are absent.

Symptoms may include: gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Vitamin C overdosage may cause acidosis and haemolytic anaemia in predisposed individuals (glucose 6-phosphate dehydrogenase deficiency). Renal failure may occur in massive Vitamin C overdosage.

Treatment: The ingested Gradumet matrix cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the Gradumet without harming the gastric mucosa. Accordingly, when overdosage is discovered early, the following procedure is recommended:

1. Administer an emetic by stomach tube.
2. Withdraw the stomach tube and wait for the patient to vomit.
3. Keep the patient under constant surveillance to detect possible aspiration of vomitus; maintain suction apparatus and standby emergency oxygen in case of need.
4. Examine the vomitus for returned Gradumet tablets.
5. Administer a saline cathartic. By the time toxic signs have appeared, Gradumet tablets are in most cases past the pylorus so that emesis is of no value. Gastric lavage may be considered to remove amounts of the drug already released in the stomach. A saline cathartic then should be given to speed the Gradumet tablets along the alimentary canal so as to minimise or prevent further absorption of the medication.
6. The use of an iron chelating agent such as oral desferrioxamine should be considered. In severe cases parenteral desferrioxamine may be necessary.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Ferrograd C is supplied in 5 carton packs, each carton containing 30 (2 × 15) tablets.

Product licence number 0037/5001.

FERROGRAD* FOLIC

Presentation A two-layered (red and yellow), round, bi-convex Filmtab* (film-coated tablet Abbott). Each tablet contains Dried Ferrous Sulphate BP 325 mg (equivalent to 105 mg elemental iron) in a sustained release form (red half – Gradumet*) and 350 mcg Folic Acid BP (yellow half).

Uses Ferrograd Folic is indicated:

1. For the prevention and treatment of iron-deficiency anaemia of pregnancy.
2. For the prophylaxis of megaloblastic anaemia of pregnancy.

The Gradumet device allows sustained release of ferrous sulphate over a number of hours, which increases iron utilisation and reduces gastro-intestinal intolerance. The device consists of an inert plastic matrix, honey-combed by thousands of narrow passages which contain the active drug together with a water-soluble channelling agent. As the tablet passes down the gastro-intestinal tract the iron is leached out. The spent matrix is finally excreted in the stools. Folic acid requirements in pregnancy can be met with supplements of between 300 and 400 mcg daily. Without such supplements folate deficiency may develop leading to megaloblastic anaemia with attendant obstetric risks. Doses over 400 mcg may mask undiagnosed primary B₁₂ deficiency.

In the extremely unlikely event of this condition occurring in a pregnant woman, the safe prophylactic dose is considered to be 350 mcg.

Dosage and administration *Recommended adult oral dosage:* 1 tablet daily before food throughout pregnancy and during the first month of the puerperium. *Children:* not applicable.

Contra-indications, warnings, etc

Contra-indications: Megaloblastic anaemia due to primary vitamin B₁₂ deficiency.

Side-effects: Those associated with conventional oral iron preparations such as nausea, vomiting, diarrhoea and/or constipation, are less likely to occur. Because of the sustained release pattern, only a small amount of the iron is released in the stomach, which is never exposed to large amounts of iron as is the case with ordinary tablets. The clinical advantages which follow are twofold – minimal side-effects and efficient absorption.

Precautions: As with all iron preparations Ferrograd Folic should be given with care in patients with haemochromatosis, haemolytic anaemias or haemoglobinopathies. Interaction (chelation) with tetracyclines. Ferrograd Folic tablets should be kept out of children's reach.

Overdosage: *Symptoms:* The initial symptoms of massive ferrous sulphate overdosage are absent, the delayed release allowing sufficient time for gastric lavage and

other forms of treatment to be effective before absorption occurs to any extent. Treatment should not be delayed, therefore, even if immediate symptoms are absent. Symptoms may include gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Treatment: The ingested Gradumet matrix cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the Gradumet without harming the gastric mucosa. Accordingly, when overdosage is discovered early, the following procedure is recommended:

1. Administer an emetic by stomach tube.
2. Withdraw the stomach tube and wait for the patient to vomit.
3. Keep the patient under constant surveillance to detect possible aspiration of vomitus; maintain suction apparatus and standby emergency oxygen in case of need.
4. Examine the vomitus for returned Gradumet tablets.
5. Administer a saline cathartic. By the time toxic signs have appeared, Gradumet tablets are in most cases past the pylorus so that emesis is of no value. Gastric lavage may be considered to remove amounts of the drug already released in the stomach. A saline cathartic then should be given to speed the Gradumet tablets along the alimentary canal so as to minimise or prevent further absorption of the medication.
6. The use of an iron chelating agent such as oral desferrioxamine should be considered. In severe cases, parenteral desferrioxamine may be necessary.

Pharmaceutical precautions Store below 20°C.

Legal category POM.

Package quantities Ferrograd Folic is supplied in 5 carton packs, each carton containing 30 (2 × 15) tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.3 g per tablet.

Product licence number 0037/5002.

HARMOGEN*

Presentation Each scored, peach coloured, flat, elongated tablet contains 1.5 mg Harmogen (piperazine oestrone sulphate), equivalent to 0.93 mg of oestrone. The tablets are marked LV.

Uses Oestrogen replacement therapy and relief of oestrogen deficiency symptoms at or after the menopause, and following surgical or radiotherapeutic oophorectomy for example:

- (a) vasomotor symptoms – hot flushes, palpitations, nocturnal sweating.
- (b) urogenital symptoms – senile atrophic vaginitis, urethritis and urethral syndrome, pruritus vulvae.
- (c) psychomotor symptoms – depression, irritability, sleep disturbances including insomnia.

Dosage and administration 1.5–4.5 mg daily, taken orally as a single dose, or may be divided. As with most drugs the dosage should be adjusted to the minimum required to control symptoms. It may be necessary to divide the daily dose if gastro-intestinal irritation becomes a problem. Replacement therapy: clinical studies indicate that two Harmogen tablets daily is a satisfactory

starting dose. Daily dose should be increased or decreased according to clinical response. The scored tablet can be easily broken in half, facilitating small adjustments of dose. The maintenance dose should be the lowest that controls the symptoms adequately. If breakthrough bleeding, breast tenderness or abdominal cramps occur, the dose should be reduced until the symptoms are just suppressed. Maintenance dosage is usually prescribed for periods of three to four weeks alternating with rest periods for five to seven days. Withdrawal bleeding may occur towards the end of the rest period. It may be preferable in some patients to give Harmogen continuously and to add a progestational agent every four to six weeks to evoke a menstrual period. Harmogen's effectiveness can be determined by both symptomatic improvement and an improvement in the vaginal cytology.

For senile vaginitis, kraurosis and pruritus vulvae, a dose of one to three Harmogen tablets is given daily according to the needs of the individual patient. The usual dose is one tablet twice daily.

Contra-indications, warnings, etc

Contra-indications: Genital or mammary malignancy. Liver dysfunction. Existing or previous thromboembolic disease. Disorders of carbohydrate or lipid metabolism. Undiagnosed abnormal bleeding from the genital tract. Pregnancy. Renal insufficiency. Even though oestrogens have proved useful in the palliation of some cases of disseminated carcinoma of the breast, they may actually accelerate the spread and growth of the tumour in other cases.

Precautions: Oestrogen withdrawal bleeding during cyclical therapy of female patients is a natural occurrence. However, bleeding while on oestrogens could be 'breakthrough' if daily oestrogen dosage needs adjusting, or it could indicate the development of a pathological condition unrelated to oestrogen therapy, e.g. fibroids, malignancy, etc. The occurrence of irregular bleeding or spotting should be thoroughly investigated in premenopausal and post-menopausal women.

Prolonged exposure to unopposed oestrogens may increase the risk of the development of endometrial carcinoma.

Adverse effects of oestrogen therapy on blood pressure and gall bladder function have been reported.

Side-effects: Studies with Harmogen have shown that the incidence of side-effects is low in women treated for menopausal symptoms. Nausea is the most frequent side-effect, but this seldom interferes with eating and tends to subside with continued therapy or reduction of dosage. With oestrogens in general, less common side-effects include sodium and water retention, breast swelling and tenderness, anorexia, vomiting, headaches, changes in liver function and breakthrough bleeding. Rare reactions include allergies, jaundice, increased blood sugar levels, decreased glucose tolerance and loss or increase of libido. Oestrogens may precipitate or aggravate porphyria cutanea tarda in predisposed individuals.

Overdosage: Symptoms: nausea, vomiting, breast enlargement, vaginal bleeding.

Treatment: Gastric lavage, emesis and general supportive measures.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Harmogen is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.2 g per tablet.

The amount of piperazine in Harmogen is not sufficient to exert a pharmacological action but its addition ensures solubility, stability and uniform potency.

Product licence number 0037/5064.

HARMONYL*

Presentation Harmony is a crystalline alkaloid isolated from the root of *Rauwolfia canescens*. Each grooved, pink tablet contains 0.25 mg deserpidine.

Uses Harmony can be used alone in the management of mild essential hypertension. It can be combined with benzothiadiazines such as methyclothiazide or other potent antihypertensive agents in the treatment of more severe cases. Such a combination often proves beneficial in the management of hypertension which is unresponsive to diuretic or Rauwolfia therapy alone.

Dosage and administration Treatment may start with one 0.25 mg tablet daily either as a single oral dose or 0.125 mg (half of the scored tablet) twice daily. This dose can be increased if necessary up to 0.25 mg four times daily. As 10–14 days are required for the drug to produce its full effect, adjustments in dosage should not be made more frequently. If the therapeutic response is not adequate it is advisable to add another antihypertensive to the therapy.

For children, doses are reduced in proportion to body weight.

Contra-indications, warnings, etc

Contra-indications: Patients with severe suicidal tendencies, active peptic ulcer and ulcerative colitis.

Precautions: Harmony should be used cautiously in patients who have a history of peptic ulcer because the drug causes a rise in free and total hydrochloric acid and an increase in the volume of gastric secretion. Some authorities suggest withdrawal or dose reduction two weeks prior to elective surgery. An unexpected degree of hypotension and bradycardia has been reported in patients undergoing anaesthesia while under treatment with Rauwolfia alkaloids. When emergency surgical procedures are necessary, parenteral administration of vagal blocking agents to prevent or reverse hypotension and/or bradycardia may be considered. In epileptic patients therapy may necessitate dosage adjustments of anticonvulsant medication: Rauwolfia alkaloids lower the convulsive threshold and shorten the latent period between stimulus and seizure. This factor should be taken into account in patients undergoing electro-shock treatment. As with all Rauwolfia preparations, severe mental depression has appeared in a small percentage of patients. When Harmony is discontinued depression usually disappears but active treatment is sometimes required. Watch for symptoms of depression, particularly in patients whose histories are questionable. Alert responsible members of the family to the problem.

Side-effects: Adverse effects encountered with Harmony are infrequent and usually mild in character. Qualitatively similar to those reported for reserpine, the incidence of these untoward effects, particularly lethargy and depression, is lower. They may include nasal

stuffiness, diarrhoea, nausea, headache, weight gain, reduction in libido and potency, aggravation of peptic ulcer, epistaxis and skin eruptions. Other side-effects are excessive drowsiness, fatigue, weakness, dizziness, anorexia, asthma in susceptible persons, nightmares which may be early signs of mental depression and eventually may lead to suicidal attempts. Any antihypertensive agent, including Harmonyl, which can cause significant hypotension may precipitate angina in patients with arteriosclerosis who are prone to angina pectoris. Electrolyte imbalance and excessive salivation have been reported during deserpidine therapy. When adverse reactions occur, they are usually reversible and disappear when the drug is discontinued.

Overdosage: Symptoms: Central depression, hypotension, ptosis, miosis and catatonias in severe cases.

Treatment: Administration of methylamphetamine hydrochloride, in a dosage of 5–15 mg orally for adults. More severe cases may require 10–30 mg intravenously or intramuscularly.

Treatment should be initiated with the smaller dose.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Harmonyl is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.12 g per tablet.

Product licence number 0037/5071.

IBERET* 500 ▼

Presentation Each red Filmtab* (film-coated tablet Abbott) contains, in a sustained release form (Gradumet*):

Dried Ferrous Sulphate BP	325 mg
(equivalent to 105 mg elemental iron)	
Ascorbic acid (vitamin C, as Na salt)	500 mg
Nicotinamide BP	30 mg
Thiamine Mononitrate USP (vitamin B ₁)	6 mg
Riboflavin (vitamin B ₂)	6 mg
Calcium Pantothenate USP	10 mg
Pyridoxine Hydrochloride BP (vitamin B ₆)	5 mg

Uses Iberet 500 combines the advantages of ferrous sulphate in the Gradumet form with a large dose of vitamin C. It also contains water-soluble B vitamins.

It is indicated in the treatment of iron-deficiency anaemia and for the simultaneous treatment of vitamin C deficiency. Vitamin C enhances the absorption of iron and is therefore valuable where poor absorption is a problem. It also promotes haemopoiesis in patients where an underlying deficiency of the vitamin limits optimal haemoglobin formation.

Iberet 500 is also indicated in the prophylaxis of iron and vitamin B and C deficient states arising particularly from dietary factors, for example in the elderly person.

The Gradumet device consists of an inert plastic matrix, honeycombed by thousands of narrow passages which contain the active drug, together with a water-soluble channelling agent. As the tablet passes down the gastro-intestinal tract the iron is leached out. The spent matrix is finally excreted in the stools.

The device releases only a small amount of iron in the stomach which is never exposed to large amounts as is the case with ordinary tablets. The clinical advantages

are twofold: minimal side-effects and efficient absorption.

The vitamins are in a layer enclosing the matrix.

Dosage and administration *Adults:* One tablet daily before food. The tablet must be swallowed whole, with a little water if necessary.

Children: Not suitable for children under twelve years of age.

Contra-indications, warnings, etc The usual care should be taken in the use of this product in patients with haemoglobinopathies, haemochromatosis and haemolytic anaemias.

In high doses pyridoxine is known to interfere with prolactin release and may be contra-indicated in nursing mothers.

Pyridoxine is known to interfere with levodopa.

Interaction (chelation) with tetracyclines.

Iberet 500 tablets should be kept out of children's reach.

Side-effects: The side-effects associated with conventional oral iron preparations, e.g. nausea, vomiting, diarrhoea or constipation, are less likely to occur.

Overdosage: In achievable overdose, the only constituents which will cause concern are the iron and, possibly, vitamin C which may cause acidosis and haemolytic anaemia in predisposed individuals (glucose-6-phosphate dehydrogenase deficiency). Renal failure may occur in massive vitamin C overdose.

Iron overdose symptoms: The initial symptoms of massive ferrous sulphate overdose are absent, the delayed release allowing sufficient time for gastric lavage and other forms of treatment to be effective before absorption occurs to any extent. Treatment should not be delayed therefore, even if immediate symptoms are absent.

Symptoms may include: gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Treatment: The ingested Gradumet cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the matrix without harming the gastric mucosa. An emetic may return the Gradumets from the stomach. When toxic signs have appeared, the tablets are likely to have passed the pylorus and emesis will be of no use. A saline cathartic may speed passage along the gut and reduce the time available for iron absorption.

The patient should be kept under observation and due consideration given to the use of standard treatments for iron overdose, including the use of chelating agents such as oral desferrioxamine. In severe cases parenteral desferrioxamine may be necessary.

Warning: Administration of therapeutic doses of ascorbic acid may interfere with the Clinistix test for glucosuria giving a false negative result.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Iberet 500 is supplied in packs of five cartons, each carton containing 30 (2 × 15) tablets.

Further information Iberet 500 does not contain vitamin B₁₂. Metabolisable carbohydrate content: nil.

Product licence number 0037/0097.

IBEROL*

Presentation Each red Filmtab* (film-coated tablet Abbott) contains:

Dried Ferrous Sulphate BP	325 mg
(equivalent to 105 mg elemental iron)	
Ascorbic acid (as sodium ascorbate)	75 mg
Liver fraction 2 NF XI	100 mg
Thiamine Mononitrate USP	3 mg
Riboflavin BP	3 mg
Nicotinamide BP	15 mg
Pyridoxine Hydrochloride BP	1.5 mg

Uses Iberol is indicated for the treatment of iron-deficiency and nutritional anaemias: during convalescence (especially after gastrectomy) and in old age.

Dosage and administration Recommended oral adult dose is 2 tablets daily.

Not recommended for children under 12 years of age.

Contra-indications, warnings, etc As with all iron preparations Iberol should be given with care in patients with haemochromatosis, haemolytic anaemias or haemoglobinopathies. In high doses pyridoxine is known to interfere with prolactin release and may be contra-indicated in nursing mothers. Tablets should be kept out of the reach of children.

Overdosage: Symptoms: gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Treatment: Gastric lavage or induced emesis. The use of an iron chelating agent such as oral desferrioxamine should be considered. In severe cases parenteral desferrioxamine may be necessary.

Pharmaceutical precautions Keep the bottle tightly closed.

Legal category P.

Package quantities Iberol is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.12 g per tablet.

Product licence number 0037/5004.

IROFOL* C

Presentation Each two-layered, red Filmtab* (film-coated tablet Abbott) contains Dried Ferrous Sulphate BP 325 mg (equivalent to 105 mg elemental iron) in a sustained release form (the Gradumet*), 500 mg vitamin C (as sodium ascorbate) and 350 mcg Folic Acid BP.

Uses

1. For the prevention and treatment of iron-deficiency anaemia during pregnancy.
2. For the prophylaxis of megaloblastic anaemia during pregnancy.
3. For the simultaneous treatment of vitamin C deficiency.

The Gradumet device allows sustained release of ferrous sulphate over a number of hours which increases iron utilisation and reduces gastro-intestinal intolerance. The device consists of an inert plastic matrix, honey-combed by thousands of narrow passages which contain the active drug together with a water soluble channelling agent. As the tablet passes down the gastro-intestinal

tract the iron is leached out. The spent matrix is finally excreted in the stools. Irofol C combines the advantages of ferrous sulphate in the slow release form with a large dose of vitamin C further to enhance iron absorption, and to produce haemopoiesis in patients where an underlying Vitamin C deficiency limits optimal haemoglobin formation.

During pregnancy folic acid requirements can be met with between 300–400 mcg daily. Without such supplementation folate deficiency may develop leading to megaloblastic anaemia with attendant obstetric risks. Doses over 400 mcg may mask undiagnosed primary B₁₂ deficiency, in the extremely unlikely event of this condition occurring in a pregnant woman, so the safe prophylactic dose is considered to be 350 mcg.

Dosage and administration *Recommended oral dosage:* 1 tablet a day before food throughout pregnancy. Children not applicable.

Contra-indications, warnings, etc

Contra-indications: Megaloblastic anaemia due to vitamin B₁₂ deficiency.

Precautions: As with all iron preparations Irofol C should be given with care in patients with haemochromatosis, haemolytic anaemia or haemoglobinopathies. Interaction (chelation) with tetracyclines. Irofol C should be kept out of children's reach.

Warning: Administration of therapeutic doses of ascorbic acid may interfere with the Clinistix test for glucosuria giving a false negative result.

Side-effects: Those associated with conventional oral iron preparations, such as nausea, vomiting, diarrhoea and/or constipation, are less likely to occur. Because of the sustained release pattern only a small amount of the iron is released in the stomach, which is never exposed to large amounts of iron as is the case with ordinary tablets. The clinical advantages which follow are twofold – minimal side-effects and efficient absorption.

Overdosage: Symptoms: The initial symptoms of massive ferrous sulphate overdosage are absent, the delayed release allowing sufficient time for gastric lavage and other forms of treatment to be effective before absorption occurs to any extent. Treatment should not be delayed, therefore, even if immediate symptoms are absent. Symptoms may include gastro-intestinal irritation, lassitude, haematemesis, diarrhoea, cardiovascular collapse. A transient recovery followed by a relapse 24–48 hours after ingestion may occur.

Vitamin C overdosage may cause acidosis and haemolytic anaemia in predisposed individuals (glucose 6 – phosphate dehydrogenase deficiency). Renal failure may occur in massive Vitamin C overdosage.

Treatment: The ingested matrix cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the matrix without harming the gastric mucosa. Accordingly, when overdosage is discovered early, the following procedure is recommended.

1. Administer an emetic by stomach tube.
2. Withdraw the stomach tube and wait for the patient to vomit.
3. Keep the patient under constant surveillance to detect possible aspiration of vomitus, maintain suction apparatus and standby emergency oxygen in case of need.
4. Examine the vomitus for returned Gradumet tablets.
5. Administer a saline cathartic. By the time toxic

signs have appeared, Gradumet tablets are in most cases of no value. Gastric lavage may be considered to remove amounts of the drug already released in the stomach. A saline cathartic should be given to speed the Gradumet tablets along the alimentary canal so as to minimise or prevent further absorption of the medication.

6. The use of an iron chelating agent such as oral desferrioxamine should be considered. In severe cases parenteral desferrioxamine may be necessary.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Irofol C is supplied in 5 carton packs, each carton containing 30 (2 × 15) tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.01 g per tablet.

Product licence number 0037/5003.

NEMBUTAL*

Presentation Nembutal is available in yellow capsules, each capsule containing 100 mg Pentobarbitone Sodium BP.

Uses Nembutal is indicated for severe intractable insomnia.

Dosage and administration Recommended oral dose 100–200 mg.

Contra-indications, warnings, etc

Contra-indications: Uncontrolled pain; children and young adults; the elderly and debilitated; pregnancy and breast feeding; patients with a history of alcohol or drug abuse; porphyria.

Precautions: Reduce dose in patients with renal or hepatic failure. (See also under Adverse Effects).

Drug interactions: Barbiturates cause induction of liver enzymes, so that the availability and blood concentrations of drugs given concurrently that are metabolised in the liver may be affected. These include the following: coumarin-type anticoagulants; systemic steroids (including oral contraceptives); phenytoin; griseofulvin; rifampicin; phenothiazines such as chlorpromazine; tricyclic antidepressants.

Adverse effects: Common adverse effects include drowsiness, sedation, unsteadiness, vertigo and incoordination. Performance and alertness may be impaired during the first week of administration. Patients should be warned of the possible hazard when driving or operating machinery. These effects may be potentiated by alcohol. Other adverse reactions may include a 'hangover' effect, paradoxical excitement, confusion, memory defects, and rashes in patients who may be sensitive to this type of drug.

Overdosage: Symptoms: Stupor, coma, respiratory depression. Hypothermia, hypotension and bradycardia may be observed in severe cases.

Treatment: Gastric lavage and general supportive treatment as in poisoning by other barbiturates. The use of amphetamines may be considered. The use of anaesthetic drugs is controversial, but it is generally agreed that their administration represents at the best an emergency measure, additional to but not replacing the all important

supportive therapy. Peritoneal dialysis and the artificial kidney have been successfully employed.

Further information: Addiction potential: Barbiturates have a high addiction potential. Long-term use or use of high dosage for short periods may lead to tolerance and subsequently to physical and psychological dependence. Symptoms of dependence include confusion, defective judgement and loss of emotional control. Withdrawal symptoms occur after long-term normal use (and particularly after abuse) on rapid cessation of barbiturate treatment. Symptoms include nightmares, irritability and insomnia and, in severe cases, tremors, delirium, convulsions and death. Withdrawal symptoms have been reported in neonates after barbiturate treatment during pregnancy and labour.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Nembutal Capsules 100 mg are supplied in containers of 500 and 1,000.

Further information *Metabolisable carbohydrate content:* Nembutal 100 mg, approx. 0.02 g per capsule.

Product licence number 0037/5005.

PARADIONE*

Presentation Paraldione is supplied in red, soft gelatine capsules, each capsule containing 300 mg paraldione.

Uses Paraldione is indicated in the treatment of the petit mal triad (petit mal, akinetic and myoclonic epilepsy) diagnosed clinically or by the typical spike and dome wave on the electroencephalograph or both. The drug does not control grand mal seizures.

Paraldione is most effective in idiopathic epilepsy, but may be used in seizures due to organic brain damage if the symptoms associated with petit mal epilepsy are present. In patients exhibiting both grand mal and petit mal seizures, Paraldione may be used with a suitable grand-mal anticonvulsant.

Note: Paraldione appears to be somewhat less potent than Tridione against clinical petit mal, but may be preferred because it produces a lower incidence of visual disturbances. Paraldione has in general been associated with a lower incidence of serious side-effects than Tridione.

Dosage and administration The dosage of Paraldione must be adjusted for each patient at the level which controls symptoms without producing undesirable effects.

Initial dosage for adults and older children: 0.9 g daily in divided doses.

Initial dosage for children 2–6 years: 0.6 g daily in divided doses.

The initial dosage should be increased at weekly or fortnightly intervals by 300 mg per day until relief is obtained, until toxic symptoms appear, or until double the initial dose is being administered. Maintenance dosage should be adjusted to the minimum required to maintain control.

Contra-indications, warnings, etc

Contra-indications: Severe hepatic or renal impairment

and blood dyscrasias. Known hypersensitivity to paramethadione.

Warning – usage in pregnancy: Recent reports suggest that certain anticonvulsant drugs including Paradione are associated with an increased incidence of congenital malformations among the offspring of women receiving these drugs at the time of conception and subsequent pregnancy. Therefore the usage of these drugs in pregnant women or in women of childbearing age should be avoided if possible. The safety of Paradione for use during lactation has not been established.

Precautions: Paradione should be withdrawn promptly at the appearance of a skin rash, because of the grave possibility of exfoliative dermatitis or erythema multiforme. Even a minor acne-like or morbilliform rash should be allowed to clear completely before treatment with the drug is resumed, and in such cases therapy should be reinstituted cautiously. A moderate degree of neutropenia with or without a corresponding drop in the leucocyte count may occur, but this does not call for withdrawal of therapy unless the total number of neutrophils drops to 2,500 per mm³ or below; frequent blood examination should be made when the count is less than 3,000. More severe haematological complications, including fatal aplastic anaemia, have occurred.

A nephrotic syndrome and hepatitis have been reported with fatalities. It is essential, therefore, that strict medical supervision be maintained during the initial period of treatment, and that examinations including laboratory tests of the blood and urine be conducted at monthly intervals. Albuminuria is an indication for withdrawing the medication. If jaundice or other signs of hepatitis appear, therapy should be discontinued. Paradione should not be used in patients with severe hepatic or renal impairment or blood dyscrasias. Caution is necessary in patients with diseases of the retina or optic nerve. If scotomata are encountered therapy should be discontinued. Other drugs known to cause toxic effects should be avoided or used only with extreme caution during therapy with Paradione.

Side-effects: The most common side-effects are drowsiness (sedation) and blurring of vision in bright light (hemeralopia). The latter also has been described as the 'glare phenomenon'. Drowsiness tends to subside with continued therapy or can be overcome by the concurrent administration of an amphetamine, without loss of anti-epileptic effect. Hemeralopia occurs mainly in adult patients, the effect being much less frequently encountered in children. This disturbance of vision results from a retinal rather than a central action of the drug, is not due to toxic damage, and disappears when therapy is withdrawn or the dosage is reduced. This sensitivity to bright light can usually be tolerated if dark glasses are worn. Gastro-intestinal effects reported are hiccups, nausea, vomiting, abdominal pain and gastric disturbances.

Anorexia and weight loss have also been reported. Skin rashes, bleeding gums, epistaxis, retinal and petechial haemorrhages, vaginal bleeding and certain blood dyscrasias including leucopenia, neutropenia, thrombocytopenia, pancytopenia, agranulocytosis and hypoplastic anaemia have been reported in patients given Paradione. A lupus erythematosus syndrome has been reported to be associated with administration of Paradione.

Other reactions include changes in blood pressure albuminuria and nephrosis, hepatitis, and precipitation of grand-mal seizures. Hair loss has been reported to

occur in some patients receiving Paradione and only rarely in patients on Tridione; in such instances, consideration should be given to alternative medication.

Overdosage: Symptoms: These include nausea, drowsiness, dizziness, ataxia and visual disturbances. Coma may follow massive overdosage.

Treatment: Vomiting should be induced or gastric lavage instituted. General supportive measures will be necessary. A careful evaluation of liver and renal function and of the blood-forming organs should be made following recovery.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Paradione is supplied in containers of 100 capsules.

Further information Contains no metabolisable carbohydrate.

Product licence number 0037/5077.

PEGANONE*

Presentation Each grooved, white tablet contains 500 mg of ethosin.

Uses Peganone is an anticonvulsant of the hydantoin series, indicated primarily in grand mal epilepsy, and to a lesser extent in the management of psychomotor seizures. It may be of benefit to some patients with petit mal and petit mal variant seizures. In patients with grand mal seizures not previously treated, Peganone may give excellent control with a minimum of side-effects. Peganone may be added to existing therapy when treatment is proving unsuccessful. This may permit a reduction in dosage of the other medications, the incidence of side-effects may be reduced and the therapeutic effect improved.

Dosage and administration In adults the initial oral dosage of Peganone is 1 g daily, increasing by 500 mg at intervals of several days until a level of 2–3 g daily is reached. This should be given in 4–6 divided doses, after food. Less than 2 g per day has been found to be ineffective in most adults. In children the initial dose should be 500 mg per day in divided doses increasing up to 1 g daily or more if necessary. If the patient is already receiving another anticonvulsant it should not be discontinued when Peganone therapy is started. The dosage of the other drug should be reduced gradually as that of Peganone is increased. Peganone may eventually replace the other drug or the optimum dosage of both anticonvulsants may be established. Peganone is compatible with other commonly used anticonvulsants.

Contra-indications, warnings, etc **Warning—usage in pregnancy:** The safety of Peganone during pregnancy, lactation and in women of childbearing age has not been established. Therefore the use of this drug in pregnant women or in women of childbearing age should be avoided if possible.

Evidence suggests that hydantoin compounds may interfere with folic acid metabolism, precipitating a megaloblastic anaemia. If this should occur during gestation, folic acid therapy should be considered.

Its use in combination with other drugs known to adversely affect the haemopoietic system should be avoided if possible.

Side-effects: The published incidence of side-effects is low, but, as Peganone is a hydantoin compound, blood counts and urine examinations should be carried out at monthly intervals, for several months from the start of therapy. As in patients receiving other hydantoin compounds blood dyscrasias have been reported, on rare occasions, in patients receiving Peganone. Its use in combination with other drugs known adversely to affect the haemopoietic system should be avoided if possible.

Although the causative role of Peganone has not been definitely established, physicians should be alert for general malaise, sore throat and other symptoms indicative of early blood dyscrasias. If clinical evidence suggests an hepatic disorder, liver function tests should be undertaken. Signs of liver damage or marked depression of the blood count are indications for withdrawal of the drug.

Occasionally, nausea or vomiting after ingestion of Peganone has been reported, but, if the drug is administered after meals, the incidence of gastric disturbances is very low. Other side-effects include fatigue, dizziness, headache, diplopia, nystagmus, skin rash, numbness, fever, diarrhoea and chest pain. Ataxia and gum hypertrophy have occurred rarely – usually in patients receiving an additional hydantoin derivative. Ataxia and gum hypertrophy produced by other hydantoins can subside when Peganone is substituted. Isolated cases of lymphadenopathy and systemic lupus erythematosus have been reported in patients taking hydantoin compounds, and lymphadenopathy has occurred with Peganone. The withdrawal of therapy can result in remission of the clinical and pathological findings. If a lymphoma-like syndrome develops, therefore, the drug should be withdrawn and the patient closely observed for regression before treatment is reinstituted.

Overdosage: Symptoms: Drowsiness, visual disturbance, nausea, ataxia. Coma is theoretically possible at very high dosage but has not been reported.

Treatment: Provoke vomiting or undertake gastric lavage. General supportive measures. The follow-up should include careful evaluation of blood-forming organs.

Compatibility: Peganone is compatible with all commonly employed anticonvulsant medications. In grand mal seizures use of the drug with phenobarbitone may be beneficial. Peganone may be used in combination with drugs such as troxidone or paramethadione, as an adjunct in those patients with petit mal associated with grand mal.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Peganone is supplied in containers of 100 tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.1 g per tablet.

Product licence number 0037/5054.

PENTHRANE*

Presentation Penthrane (Methoxyflurane BP) is an anaesthetic agent for inhalation. It is a clear, almost colourless liquid with a characteristic fruity odour. An antioxidant, butylated hydroxytoluene 0.01% w/w is added to ensure stability on standing.

Uses When used for obstetric patients, light planes of

Penthrane anaesthesia have little effect on uterine contractions. There are no known contra-indications to the concomitant use of Penthrane and oxytocic agents.

During general anaesthesia bronchial constriction and laryngeal spasm are not usually produced by Penthrane.

Characteristically during Penthrane anaesthesia satisfactory cardiovascular stability is maintained. The myocardium is only minimally sensitised by Penthrane to adrenaline. Some decrease in blood pressure often accompanies light planes of anaesthesia. This may be associated with bradycardia. This hypotension, usually of not more than 20 mm Hg, is accompanied by a reduced contractile force of the heart muscle and reduced cardiac output.

Following surgical anaesthesia with Penthrane, analgesia and drowsiness may persist after consciousness has returned. This may obviate or reduce the need for sedation in the immediate post-operative period.

Penthrane provides analgesia or anaesthesia.

Indications for analgesia: For the relief of pain during labour.

The Central Midwives Boards and the Joint Nursing and Midwives Council for the Northern Ireland Authority have approved the use of Penthrane in conjunction with the specifically designed Cardiff Inhaler for use by midwives for analgesia during labour.

Indications for anaesthesia: Penthrane is an inhalation agent indicated for general anaesthesia. It is recommended to be used with nitrous oxide, but it may be administered as the sole inhalation agent when nitrous oxide is not available. When Penthrane is used alone with oxygen or air as the carrier gas, increased concentrations must be used.

Dosage and administration *For analgesia:* Vapour concentrations in the range of 0.3–0.8% are recommended. Penthrane may be self-administered by draw-over inhalers (such as Cyprane) if the patients are kept under close observation. The patient in labour may receive a fixed optimal concentration of 0.35% Penthrane in air from a Cardiff Inhaler. Compensatory devices within the instrument prevent significant variations in respiratory rate and volume and ambient temperature which may occur in clinical practice. Penthrane does not interfere with uterine action and the progress of labour is not slowed.

Important note: For intermittent administration from this inhaler, the dosage for each patient must be limited to the vapour from not more than 15 ml of liquid Penthrane. In practice this is rarely exceeded during use of the inhaler for the indication listed. If anaesthesia is required then the recommendations given below should be followed.

For general anaesthesia: The lowest effective dosage of Penthrane should be used in order to minimise the possibility of renal dysfunction and to allow for optimal recovery time. Deeper planes of anaesthesia should be avoided. It is recommended that Penthrane should be administered with a carrier gas consisting of at least 50% nitrous oxide.

1. **Levels and signs:** See the table opposite.

2. **Apparatus:** Penthrane should be administered with calibrated temperature compensated out-of-circle vaporisers (e.g. Pentec Mk II Penlon) or by other methods which provide accurate vapour concentrations or precise measurements of dose. The uptake of the anaesthetic by rubber tubing, bags and soda lime which may prolong induction and recovery time can be reduced by the use

of non-adsorbent plastic circuit material (not polyvinyl chloride) and fresh moist soda lime. The fresh gas inlet should be located downstream of the CO₂ absorber in order to avoid excessive absorption of anaesthetic, and the rebreathing bag and expiratory valve should be located on the expiratory side.

3. *Pre-medication:* The usual pre-anaesthetic medications may be administered prior to Penthrane anaesthesia.

4. *Carrier gas:* For general surgery, Penthrane should be administered with a carrier gas flow consisting of oxygen and at least 50% nitrous oxide in a semi-closed circuit, in order to reduce to a minimum the total Penthrane dose, unless nitrous oxide is contra-indicated.

5. *Muscle relaxation:* Adequate relaxation should be obtained by using a muscle relaxant, e.g. succinylcholine chloride, tubocurarine or pancuronium. The usual dosage of non-depolarising muscle relaxants should be reduced by approximately half. Penthrane alone should not be administered at levels required to achieve muscle relaxation.

6. *Induction:* Rapid induction should be accomplished by an ultra-short-acting barbiturate, such as thiopentone sodium for injection. Initially Penthrane concentrations may be increased as tolerated, to the maximum possible vapour concentration, i.e. approximately 3%. This maxi-

mum concentration should only be continued for about two to five minutes according to the patient's weight, or until the desired level of Penthrane anaesthesia is reached.

7. *Maintenance:* The concentration of Penthrane should then be reduced at frequent intervals to the lowest concentration which will maintain adequate anaesthesia. In general, after an hour of anaesthesia, concentrations of 0.2–0.4% should be sufficient for this purpose, with a gas flow of 5 litres/minute.

8. *Recovery:* When administration has been prolonged, Penthrane should be discontinued before the expected end of surgery by a length of time equivalent to 10 minutes for each hour the Penthrane was in use. Elimination of Penthrane is greatly aided by flushing with pure oxygen. Most patients recover quietly and without delirium or hypotension and with a minimum incidence of nausea and vomiting.

9. *Anaesthetic level and signs:*

- (a) Analgesic level – for pain relief in labour.
- (b) Light anaesthetic level – in minor surgical procedures.
- (c) Moderate anaesthetic level – for general surgical use.
- (d) Deep anaesthetic level – this level must be avoided.

PENTHRANE-LEVELS AND SIGNS

	<i>Analgesia</i>	<i>Light anaesthesia</i>	<i>Moderate anaesthesia</i>	<i>Deep anaesthesia</i>
<i>State of consciousness</i>	Drowsy	Unconscious (possible slow movements)	Unconscious (no movement)	
<i>Response to painful stimulus</i>	Decreased	Further decreased	Absent	
<i>Eyeball activity</i>	Normal	Sluggish	Fixed and central	
<i>Pupillary reaction to light</i>	Present			Absent
<i>Lid reflex</i>	Present		Absent	
<i>Tearing (after lid manipulation)</i>	Absent	Present	Absent	
<i>Skin colour</i>	Normal			Pallor
<i>Capillary refill</i>	Good			Poor to absent
<i>Blood pressure</i>	Unchanged	May drop 20 to 40 mm Hg	Usually recovers	Progressive hypotension
<i>Pulse</i>	Stable			Possible tachy- or bradycardia
<i>Respiration</i>	Stable	Irregular, long expiratory pause	Stable, shorter expiratory pause	Decreasing minute and tidal volumes
<i>Swallowing and protective reflexes</i>	Present		Absent	
<i>Muscle relaxation</i>	None	Superficial (e.g. jaw)	Mild	Fair to good

† Not recommended with Penthrane.

- (e) Signs – the signs of Penthrane anaesthesia should be observed closely as a guide to a proper depth. Signs of each level are clearly identifiable (see the table opposite).

Contra-indications, warnings, etc

Contra-indications: Penthrane should not be used when previous exposure to this agent or to other halogenated anaesthetics has been followed by jaundice and/or unexplained fever, because of the possibility of hepatic toxicity. Cross-sensitivity between Penthrane and halothane has been reported.

Important note: *Penthrane should not be readministered within a month.*

Precautions: Occurrence of renal dysfunction has been associated with *excessive dosage of Penthrane*. This has ranged in severity from transient alterations in biochemical values to irreversible renal failure. It is believed that these effects are associated with elevated serum inorganic fluoride levels. After Penthrane anaesthesia, serum inorganic fluoride and urinary inorganic fluoride and oxalate concentrations increase, indicating that these substances are products of Penthrane metabolism. These are dose-related effects. Therefore, the recommended dosage should be followed, unless, in the judgement of the physician, the potential benefits outweigh the risks. The lowest effective dosage should be administered especially in aged or obese patients and in surgical procedures of long duration, bearing in mind that the total dose delivered to the patient is in the main a factor of duration of administration and vapour concentration.

Polyuric renal insufficiency associated with excessive total dosage of Penthrane is characterised by the development, early in the post-operative period, of the following manifestations:

- High urine volume in relation to fluid intake.
- Weight loss.
- Elevation of serum sodium, chloride, uric acid, creatinine, osmolality and blood urea nitrogen (BUN).

Oliguric renal dysfunction associated with excessive total dosage of Penthrane is characterised by the following manifestations:

- Low urine volume in relation to fluid intake.
- Increased values of BUN, and serum creatinine, uric acid, chloride, and decreased values of sodium.

The guiding principles for minimising the possibility of renal involvement are:

- Avoid using Penthrane alone to achieve muscular relaxation.
- Patients with pre-existing renal disease or impairment of renal function, toxæmia of pregnancy and patients undergoing vascular surgery involving the renal vessels should not receive Penthrane unless in the judgement of the clinician the benefits outweigh the increased risk of nephrotoxic effects.
- Light or moderate anaesthesia with Penthrane should not be repeated within one month.
- All patients who receive Penthrane should be monitored for urinary output and possible laboratory signs of renal dysfunction, as indicated. Losses of fluids and electrolytes in urine or by other routes should be promptly replaced.
- The concurrent use of tetracyclines and Penthrane has been reported to result in fatal renal toxicity. Penthrane may enhance the adverse renal effects of other known nephrotoxic drugs.

Caution should be exercised in using Penthrane in patients with prolonged histories of treatment or exposure to enzyme-inducing agents (e.g. barbiturates and insecticides) as such agents may enhance the metabolism of Penthrane. Cirrhosis, a history of viral hepatitis or other abnormalities involving liver dysfunction may be the basis for selecting an anaesthetic other than a halogenated agent. Penthrane anaesthesia can possibly aggravate or superimpose renal impairment in diabetic patients with renal dysfunction, polyuria or obesity, or who are not optimally controlled.

The risk of renal toxicity is greater in obese patients because of the lipophilic properties of Penthrane and the weight-related recommended dose.

Ventilation should be assessed carefully and, if depressed, should be augmented to ensure adequate oxygenation and carbon dioxide removal. Barbiturates and narcotics, used as adjuncts, should be administered in conservative doses to avoid ventilatory depression. Penthrane causes a slight metabolic acidosis.

Penthrane augments the effect of non-depolarising muscle relaxants, therefore, their usual dosage should be reduced by approximately half.

Adrenaline or noradrenaline should be employed cautiously during Penthrane anaesthesia.

Use in pregnancy: Safe use of Penthrane other than for obstetrics has not been established with respect to adverse effects upon foetal development. Therefore, Penthrane should not be used in women of childbearing potential and particularly during early pregnancy unless, in the judgement of the physician, the potential benefits outweigh the possible hazards.

Usage in obstetrics: Attention should be given to the directions shown under dosage and administration.

The effect of inorganic fluoride in the infant is not known.

Controlled studies together with world-wide clinical experience have demonstrated that the occurrence of renal dysfunction associated with high levels of serum inorganic fluoride in either the mother or child must be considered unlikely.

Adverse reactions: Renal dysfunction (see Contra-indications, warnings, etc. Dosage and administration).

Hepatic dysfunction, jaundice, and fatal hepatic necrosis have occurred rarely following Penthrane anaesthesia. Such reactions appear to represent a sensitivity reaction to halogenated anaesthetics. Also as with other anaesthetics, transient alterations in liver function tests may follow Penthrane administration.

Some patients exhibit pallor during recovery after excessive dosage of Penthrane.

As with other anaesthetic agents for inhalation, adverse reactions which have been reported include cardiac arrest, malignant hyperpyrexia, prolonged post-operative somnolence, respiratory depression, laryngospasm, bronchospasm, nausea, vomiting, post-operative headache, hypotension and emergence delirium.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Penthrane is available in 125 ml bottles.

Further information Nil.

Product licence number 0037/5066.

SURBEX T*

Presentation Each orange-yellow ovaloid tablet contains:

Riboflavin BP	10 mg
Nicotinamide BP	100 mg
Pyridoxine Hydrochloride BP	5 mg
Ascorbic acid BP	500 mg
Thiamine Mononitrate USP	15 mg

Uses Surbex-T is indicated in vitamin B complex and vitamin C deficiencies including those arising from: debility after illness or operation, chronic alcoholism, renal dialysis, prolonged antibiotic therapy, old age and associated poor diet.

Dosage and administration Recommended oral dosage: one tablet daily, or more depending on clinical need. Children 6-12 years 1 tablet daily.

Contra-indications, warnings, etc In high doses, pyridoxine is known to interfere with prolactin release and may be contra-indicated in nursing mothers. Keep all tablets out of the reach of children.

Warning: The administration of therapeutic doses of ascorbic acid may interfere with the Clinistix test for glycosuria giving a false negative result.

Overdosage: Symptoms: In achievable overdose, the only constituent which may cause concern is Vitamin C which may cause acidosis and haemolytic anaemia in predisposed individuals (glucose 6-phosphate dehydrogenase deficiency). Renal failure may occur following massive overdose.

Treatment: Gastric lavage or induced emesis.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities Surbex-T is supplied in containers of 100 tablets.

Further information Contains no metabolisable carbohydrate.

Product licence number 0037/5012.

THEOGRAD*

Presentation Each white Filmtab* (film-coated tablet Abbott) contains 350 mg Theophylline BP in a sustained release form (Gradumet*).

Uses For the prevention or relief of bronchospasm. The Gradumet consists of a plastic matrix, honeycombed by thousands of narrow passages which contain the active drug together with a water soluble channelling agent. As the tablet passes down the gastro-intestinal tract, the theophylline is leached out; this action is quite independent of intestinal variables such as pH and enzyme effect, viscosity, ion concentration, surface tension and motility. The spent matrix is finally excreted in the stools.

Quite apart from providing a more uniform and prolonged clinical effect, the controlled release of theophylline reduces gastric irritation, often a problem with conventional preparations, to a minimum.

Dosage and administration Usual dosage: 1 tablet every 12 hours. In patients with acute symptoms 2 tablets initially, followed by 1 tablet at 12-hourly intervals.

Some patients may require to have the dose titrated to produce the desired therapeutic effect, which is usually

obtained with a serum concentration of 10-20 mcg/ml. These patients will require higher and more frequent doses.

Contra-indications, warnings, etc

Contra-indications: Theophylline is relatively non-toxic and there are no clear cut contra-indications.

Precautions: As with all adrenergic stimulants, Theograd should be used with caution in patients with cardiac arrhythmias.

Recent studies reveal that the use of erythromycin in patients who are receiving high doses of theophylline may be associated with an increase of serum theophylline levels and potential theophylline toxicity.

In case of theophylline toxicity and/or elevated serum theophylline levels, the dose of theophylline should be reduced while the patient is receiving erythromycin therapy.

Side-effects: As with all theophylline preparations, some patients may experience gastro-intestinal side-effects. However, the incidence has been reduced to a minimum by the sustained release formulation.

Overdosage: Symptoms: The delayed release of the theophylline gives extra time in which gastric lavage and general treatment may be instituted. Treatment should not be delayed, therefore, even if immediate symptoms are absent. Symptoms may include nausea, vomiting, gastro-intestinal irritation, tachycardia, hypotension.

Treatment: The ingested Gradumet cannot be readily aspirated through a stomach tube and there is no known chemical which will dissolve the Gradumet without harming the gastric mucosa. Accordingly, when overdosage is discovered early, the following procedure is recommended:

1. Administer an emetic by stomach tube.
2. Withdraw the stomach tube and wait for the patient to vomit.
3. Keep the patient under constant surveillance to detect possible aspiration of vomitus; maintain suction apparatus and standby emergency oxygen in case of need.
4. Examine vomitus for returned Gradumet tablets.
5. Administer a saline cathartic.

By the time toxic signs have appeared, Gradumet tablets are in most cases past the pylorus so that emesis is of no value. Gastric lavage may be considered to remove amounts of the drug already released in the stomach. A saline cathartic then should be given to speed the Gradumet tablets along the alimentary canal so as to minimise or prevent further absorption of the medication.

General supportive measures should be employed.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Theograd is supplied in 5 carton packs, each carton containing 30 (2 by 15) tablets.

Further information *Metabolisable carbohydrate content:* Approx. 0.02 g per tablet.

Product licence number 0037/5059.

TRIDIONE*

Presentation Tridione is supplied in white capsules containing 300 mg of Troxidone BP.

Uses Tridione is indicated in the treatment of the petit mal triad (petit mal, akinetic and myoclonic epilepsy) diagnosed clinically, or by the typical spike and dome wave on the electroencephalograph or both. The drug does not provide control of grand mal seizures. Tridione is most effective in idiopathic epilepsy, but may be used in seizures due to organic brain injury if the symptoms associated with petit mal epilepsy are present. In patients exhibiting both grand mal and petit mal seizures Tridione may be used with a suitable grand mal anticonvulsant.

Tridione appears to be somewhat more potent than Paradione against clinical petit mal, but Paradione may be preferred because it produces a lower incidence of visual disturbances. Paradione has in general been associated with a lower incidence of serious side-effects than Tridione.

Dosage and administration The dosage of Tridione must be adjusted for each patient at the level which controls symptoms without producing undesirable effects.

Initial dosage for adults and older children: 0.9 g daily in divided doses.

Initial dosage for children 2-6 years: 0.6 g daily in divided doses.

The initial dosage should be increased at weekly or fortnightly intervals by 300 mg per day until relief is obtained, until toxic symptoms appear, or until double the initial dose is being administered. Maintenance dosage should be adjusted to the minimum required to maintain control.

Contra-indications, warnings, etc

Contra-indications: Severe hepatic or renal impairment and blood dyscrasias. Known hypersensitivity to troxidone.

Warning - usage in pregnancy: Recent reports suggests that certain anticonvulsant drugs including Tridione are associated with an increased incidence of congenital malformations among the offspring of women receiving these drugs at the time of conception and subsequent pregnancy. The use therefore of these drugs in pregnant women or in women of childbearing age should be avoided if possible. The safety of Tridione for use during lactation has not been established.

Precautions: Tridione should be withdrawn promptly at the appearance of a skin rash, because of the grave possibility of exfoliative dermatitis or erythema multiforme. Even a minor acne-like or morbilliform rash should be allowed to clear completely before treatment with the drug is resumed and in such cases therapy should be reinstituted cautiously. A moderate degree of neutropenia with or without a corresponding drop in the leucocyte count may occur, but this does not call for withdrawal of therapy unless the total number of neutrophils drops to 2,500 per mm³ or below; frequent blood examination should be made when the count is less than 3,000. More severe haematological complications, including fatal aplastic anaemia, have occurred. A nephrotic syndrome and hepatitis have been reported with fatalities. It is, therefore, essential that strict medical supervision be maintained during the initial period of treatment, and that examinations including laboratory tests of the blood and urine be conducted at monthly intervals. Albuminuria is an indication for withdrawing the medication. If jaundice or other signs of hepatitis appear, therapy should be discontinued. Tridione should

not be used in patients with severe hepatic or renal impairment or blood dyscrasias. Caution is necessary in patients with disease of the retina or optic nerve. If scotomata are encountered, therapy should be discontinued. Other drugs known to cause toxic effects should be avoided or used only with extreme caution during therapy with Tridione.

Side-effects: The most common side-effects are drowsiness (sedation) and blurring of vision in bright light (hemeralopia). The latter also has been described as the 'glare phenomenon'. Drowsiness tends to subside with continued therapy or can be overcome by concurrent administration of an amphetamine without loss of anti-epileptic effect. Hemeralopia occurs mainly in adult patients, the effect being much less frequently encountered in children. This disturbance of vision results from a retinal rather than a central action of the drug, is not due to toxic damage, and disappears when therapy is withdrawn or dosage is reduced. This sensitivity to bright light can usually be tolerated if dark glasses are worn. Gastro-intestinal effects reported are hiccups, nausea, vomiting, abdominal pain and gastric disturbances.

Anorexia and weight loss have also been reported. Skin rashes, bleeding gums, epistaxis, retinal and petechial haemorrhages, vaginal bleeding and certain blood dyscrasias including leucopenia, neutropenia, thrombocytopenia, pancytopenia, agranulocytosis and hypoplastic anaemia have been reported in patients given Tridione. As with certain other anticonvulsants, a lupus erythematosus syndrome has been reported to be associated with the administration of Tridione. Similarly, lymphadenopathy simulating malignant lymphoma has occurred in patients where Tridione was among the drugs administered. If a lupus-like manifestation or lymph node enlargement should appear, therapy should be discontinued and the patient observed for improvement before specific treatment for lupus erythematosus or lymphoma is instituted. A myasthenia gravis-like syndrome also has been associated with chronic administration of Tridione. Symptoms suggestive of this condition are an indication for discontinuance of therapy.

Other reactions include changes in blood pressure, and precipitation of grand-mal seizures. Hair loss has been reported to occur in some patients receiving Paradione, but only rarely in patients on Tridione; in such instances, consideration should be given to alternative medication.

Overdosage: Symptoms: These include nausea, drowsiness, dizziness, ataxia and visual disturbances. Coma may follow massive overdosage.

Treatment: Vomiting should be induced or gastric lavage instituted. General supportive measures will be necessary. A careful evaluation of liver and renal function and of the blood-forming organs should be made following recovery.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Tridione capsules 300 mg are supplied in containers of 100.

Further information *Metabolisable carbohydrate content:* Tridione capsules, 0.15 g per capsule.

Product licence number 0037/5053.

UREAPHIL®

Presentation Ureaphil is supplied as anhydrous, lyophilised sterile urea powder in 150 ml Abbott Non-Vac® containers, containing 40 g of the powder.

Uses

1. To reduce cerebral oedema and raised intracranial pressure resulting from trauma, surgery or disease.
2. To counteract oliguria following burns, surgery or other trauma.
3. To promote an abundant flow of urine following prostatectomy and so reduce the need for frequent irrigation of the bladder.
4. To induce therapeutic abortion in the mid-trimester of pregnancy.

Note: Although urea acts as an osmotic diuretic, it is not considered the drug of choice for the management of oedema in cardiac failure.

Dosage and administration

Administration: Ureaphil is administered by slow intravenous infusion. The rate of injection should not exceed 60 drops (3–4 ml depending on drop size) per minute. Extreme care is essential to prevent accidental extravasation of the solution at the site of injection, since this may cause local reactions ranging from mild irritation to tissue necrosis. Ureaphil may be reconstituted by the addition of 5 or 10% dextrose or 10% invert sugar in water. It is administered in hypertonic concentrations of 30% (w/v) or 4% (w/v) depending upon clinical indications. To prepare a 30% solution 105 ml of diluent are added to the contents of one 40 g bottle producing 135 ml of solution.

To prepare a 4% solution, the contents of one 40 g bottle are added to 1 l of dextrose in water, producing 1,030 ml of solution. Since the dissolution is an endothermic reaction, the diluent should be warmed slightly, or the solution allowed to reach room temperature, before use. Urea will decompose if the diluent is warmed above 40°C.

Dosage: The amount to be administered is generally estimated on the basis of 1 g of urea per kg of body weight. The dosage must also take into account the clinical condition of the patient, especially the state of hydration, electrolyte balance and integrity of renal function. The total daily dose should not exceed 120 g of urea.

1. **Increased intracranial or cerebrospinal fluid pressure:** For the reduction of cerebral oedema, and increased intracranial or cerebrospinal fluid pressure, a 30% solution is usually employed. The adult dose ranges from 1.0 to 1.5 g (3.3 to 5.0 ml) per kg of body weight (0.45–0.68 g [1.5–2.3 ml] per lb). In children the dosage is from 0.5 to 1.5 g/kg of body weight. In young children up to 2 years of age as little as 0.1 g/kg can be effective.
2. **Oliguria:** To combat antidiuresis following surgery, burns or other trauma a 4% solution has produced satisfactory results. In the adult, the dose ranges from 1.0 to 1.5 g/kg of body weight. This is approximately equivalent to a volume of 1,500–3,000 ml. In children up to 5 years of age, the usual dose of the 4% solution is 1 g/kg/day, administered by slow intravenous drip. Larger doses may be required in older children.
3. **Prostatectomy:** Following prostatectomy, urea is employed as a 4% solution. Depending upon clinical circumstances, 3 litres of solution may be administered daily for three days following surgery. This is equivalent to a daily dose of 120 g of urea.

4. **Therapeutic abortion: Methods:** A sterile, suprapubic, drainage catheter is passed into the amniotic cavity, the liquor drained-off and the volume measured.

- (a) Ureaphil alone: 80 g Ureaphil dissolved in 140 ml 5% dextrose (final volume 200 ml) is given through the cannula into the amniotic cavity.

The time required to induce therapeutic abortion can be reduced by the addition of either oxytocin or prostaglandin E₂ given by methods described below:

- (b) Combined intra-amniotic Ureaphil (80 g dissolved in 140 ml 5% dextrose) and a simultaneous intravenous infusion of oxytocin (100–200 units in 500 ml Compound Sodium Lactate Injection BP – Hartmann's solution.)
- (c) Intra-amniotic Ureaphil 140 ml (80 g Ureaphil dissolved in 80 ml Hartmann's solution). When the administration of the Ureaphil solution is complete either 2.5 mg, 5 mg or 10 mg of prostaglandin E₂ in alcohol is injected. This method is particularly successful in inducing mid-trimester abortion within 24 hours.

Note: When Ureaphil is used alone, some clinicians have increased the amount of 5% dextrose solution to 210 ml (final volume 270 ml).

Contra-indications, warnings, etc

Contra-indications: Urea should not be used in patients with severely impaired renal function, active intracranial bleeding or marked dehydration. Frank liver failure is also a contra-indication for use. Ureaphil should not be infused in the veins of the lower limbs of elderly patients, since phlebitis and thrombosis of superficial veins may occur.

Precautions: Urea may cause depletion of electrolytes, which can result in hyponatraemia and hypokalaemia. Early signs of such depletion may indicate the need for supplementation before serum levels are reduced. An indwelling urethral catheter should be used in comatose patients receiving Ureaphil, to ensure bladder emptying. The rapid intravenous administration of hypertonic solutions of urea may be associated with haemolysis as well as a direct effect on the cerebral vasomotor centres, and as a result there may be increased capillary bleeding. These effects usually can be avoided by not exceeding an infusion rate of 60 drops per minute. Solutions of urea should not be administered through the same set by which blood is being infused. Although arterial oozing has been reported as a nuisance when intracranial surgery is performed on patients after they have been treated with urea, it has not been a significant problem. However, Ureaphil should not be used in the presence of active intracranial bleeding unless such use is preliminary to prompt surgical intervention to control haemorrhage. It should be borne in mind that the reduction in brain oedema induced by urea may result in reactivation of intracranial bleeding.

In the presence of kidney disease, urea should be administered with caution. Mild elevation of non-protein nitrogen does not preclude its use or continued use, but frequent laboratory studies should be made to determine if kidney function is adequate to eliminate the infused urea, as well as that produced endogenously.

Patients exhibiting a temporary reduction in urine volume are generally able to maintain a satisfactory elimination of urea. However, if diuresis does not follow the injection of urea in such patients within 6–12 hours, the drug should be withdrawn pending further evaluation.

of renal function. As with other infused solutions. Ureaphil may temporarily maintain circulatory volume and blood pressure in spite of considerable blood loss. Consequently, when excessive blood loss occurs within a short period of time, blood replacement should be adequate and simultaneous with the infusion of urea.

Hypothermia when used with urea infusion may increase the risk of venous thrombosis and haemoglobinuria.

Side-effects: Headaches (reported to be similar to those which occur in some patients following lumbar puncture), nausea, vomiting, occasional syncope and disorientation have been known to follow intravenous administration of urea. Less often reported is a transient agitated confusional state. No serious reactions have been noted when solutions have been infused slowly provided renal function is not seriously impaired and there is no evidence of active intracranial bleeding. Chemical phlebitis and thrombosis near the site of injection have been reported infrequently.

Pharmaceutical precautions Ureaphil should be used immediately after reconstitution. It should not be stored for any length of time, even in a refrigerator.

Legal category POM.

Package quantities Ureaphil is supplied in 150 ml Abbott Non-Vac[®] single use containers containing 40 g.

Further information Small quantities of sodium hydroxide may have been added to some batches for adjustment of pH.

Product licence number 0037/5072.

VI-DAYLIN[®]

Presentation A citrus-flavoured vitamin syrup formulated for infants and children. Each 5 ml contains:

Vitamin A palmitate	3,000 iu
Vitamin D (Ergocalciferol BP)	400 iu
Thiamine Hydrochloride BP	1.5 mg
Riboflavin BP	1.2 mg
Nicotinamide BP	10 mg
Pyridoxine Hydrochloride BP	1 mg
Ascorbic Acid BP	50 mg

Uses Vi-Daylin is indicated for the prevention and treatment of vitamin deficiencies in infants and children.

Dosage and administration Vi-Daylin is administered orally, and as it will not curdle milk, it may be added to an infant's feed or mixed with cereal or fruit juice.

The prophylactic dose is 2.5–5 ml daily for infants, and 5–10 ml daily for children. The therapeutic dosage is two or three times larger or as directed by the physician.

Contra-indications, warnings, etc Keep all medicines out of the reach of children. Avoid overdosage of vitamins A and D.

In the unlikely event of overdosage gastric lavage or induction of emesis should be considered.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Vi-Daylin is supplied in 100 ml and 500 ml bottles.

Further information *Metabolisable carbohydrate content:* Approx. 5.5 g per 5 ml.

Product licence number 0037/5011.

FRISIUM* ▼

Presentation Frisium capsules each contain 10 mg clobazam. Frisium is presented as hard gelatin capsules coloured powder blue opaque with 'Frisium' printed on both cap and body.

Uses Frisium is a 1,5-benzodiazepine minor tranquilizer and is indicated for the relief of acute or chronic anxiety, tension and agitation. Physical symptoms associated with an underlying anxiety state, phobias and psychosomatic disorders may all respond to treatment with Frisium as may symptoms of anxiety associated with underlying organic disease. Frisium may be used together with antidepressants in the treatment of anxiety associated with depression. Frisium has also been shown to have a beneficial effect in the treatment of sleep disturbances associated with anxiety. Frisium may be used as adjunctive therapy in epilepsy.

Dosage and administration The usual dose for adults is 20–30 mg daily in divided doses or as a single dose given at night. The lower dosage recommendation applies particularly to the elderly who are usually more sensitive to the effects of psychoactive agents.

Doses of up to 60 mg daily have been used in the treatment of hospitalised adult patients with severe anxiety states.

In epilepsy a starting dose of 20–30 mg/day is recommended, increasing as necessary up to a maximum of 60 mg daily. A break in therapy may be beneficial if drug exhaustion develops, recommencing therapy at a low dose.

Children: When prescribed for children over three years of age, dosage should not exceed half the recommended adult dose. Frisium capsules are not recommended for children under three years of age.

Contra-indications, warnings, etc *Contra-indications:* Frisium should not be used in patients known to be hypersensitive to benzodiazepines.

Precautions, warnings: Frisium is a benzodiazepine derivative and, in common with other members of this group, may potentiate the effects of central nervous system depressant drugs, such as alcohol, analgesics, hypnotics and neuroleptics. Addition of Frisium to established anticonvulsant medication may cause a change in plasma levels but no clinical effects have been reported.

The ability to drive or operate machinery may be impaired in individuals who are particularly sensitive to the effects of Frisium or in patients taking high doses.

Frisium should be used in reduced doses in patients with impaired renal or hepatic function.

There is no information on the use of Frisium in early pregnancy but no untoward effects have been found in animal studies. However, there are reports of a possible

association between malformations in infants and the administration of other benzodiazepines in early pregnancy.

Nursing mothers: Clobazam may appear in the breast milk of nursing mothers.

Overdosage: Muscle weakness, ataxia, drowsiness and sedation may occur and, after very high doses, the patient may lose consciousness. The treatment of overdosage is symptomatic. The stomach should be emptied as soon as possible by gastric lavage and general supportive measures should be undertaken as necessary.

Side-effects: Frisium is generally well tolerated. Side-effects such as drowsiness, dizziness or dryness of the mouth have been reported. These are more likely to occur at the beginning of treatment and often disappear with continued treatment or a reduction in dose.

Pharmaceutical precautions Frisium capsules should be stored in a cool, dry place in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Frisium is available as 10 mg capsules packed in blister packs of 100 capsules.

Further information Experimental evidence shows that, in general, when given as a single dose of up to 20 mg or in divided doses of up to 30 mg Frisium does not affect psychomotor function. However, individuals who are sensitive to the effects of Frisium may be adversely affected, particularly at the beginning of treatment.

Product licence number 0086/0065.

MERITAL* 50 CAPSULES ▼

MERITAL* 25 CAPSULES ▼

MERITAL* AM TABLETS ▼

Presentation Merital 50 Capsules each contain 50 mg nomifensine hydrogen maleate. The capsules have a medium orange opaque body and a caramel cap with 'Merital 50' printed on both cap and body.

Merital 25 Capsules each contain 25 mg nomifensine hydrogen maleate. The capsules are coloured medium orange opaque with 'Merital 25' printed on both cap and body.

Merital AM Tablets each contain 100 mg nomifensine hydrogen maleate. They are coloured salmon.

Uses Merital is an antidepressant indicated for the treatment of a wide range of depressive illness, including depression in which anxiety is an accompanying feature.

Initial studies have indicated that Merital is particularly suitable for patients who exhibit symptoms and signs of retardation and, in these patients, may be expected to produce a rapid beneficial effect.

Dosage and administration Many depressed patients will benefit from an initial dose of 50 mg twice or three times a day, and this may be adjusted according to response after 7–10 days. Doses of up to 100 mg may be given as a single daily dose in the morning.

For some patients, particularly the elderly, who are known to be sensitive to the effects of psychotropic drugs, the recommended initial dose is 25 mg three times a day. The normal dose range is 75–200 mg Merital daily.

Children: At the present time there is insufficient experience of the use of Merital in children to enable any dosage recommendation to be made.

Contra-indications, warnings, etc

Contra-indications: At the present time there are no known specific contra-indications to the use of Merital.

Warnings: Merital may antagonise the antihypertensive effects of adrenergic neurone-blocking drugs (e.g. bethanidine, guanethidine and debrisoquine); patients taking these drugs may require restabilisation on a higher dose of their antihypertensive therapy.

Precautions: Merital has been shown to be of value as an antidepressant in patients with Parkinson's disease but may potentiate both the therapeutic and adverse effects of levodopa and other dopamine agonists used in the treatment of this condition. When depression is a component of schizophrenic illness, Merital should be used in conjunction with a neuroleptic (e.g. a phenothiazine). In some cases, Merital has been shown to ameliorate the extra-pyramidal side-effects of this group of drugs.

All available evidence has indicated that Merital is exceptionally well tolerated, and there have been few cardiovascular effects other than mild palpitations. However, until more specific information is obtained, Merital should be used with caution in patients with ischaemic heart disease.

Merital has not been used in conjunction with electroconvulsive therapy but there is no reason to believe that such a combination will lead to any adverse effects.

Since Merital inhibits the synaptic re-uptake of biogenic amines, it should not be given concurrently

with monoamine oxidase inhibitors (MAOIs) or within two weeks of the cessation of MAOI therapy.

There is no information on the use of Merital in pregnancy but no untoward effects have been found in animal studies.

Nursing mothers: Nomifensine has been detected in breast milk in very small quantities; the effect of this low dose of nomifensine on the neonate is not known.

Overdosage: The treatment of overdosage with Merital is symptomatic. The stomach should be emptied as soon as possible by gastric lavage and the patient admitted to hospital. General supportive measures should be undertaken where indicated. However, reports of overdoses with Merital, including one patient who took 3.5 g nomifensine, have shown no serious sequelae directly attributable to the drug.

Side-effects: Merital has been shown to be exceptionally well tolerated and side-effects, when they occur, tend to be mild and transient. Reported side-effects have included sleep disturbance, restlessness, nausea, headache, palpitations, dry mouth, dizziness and a rise in body temperature. In rare cases, increases in liver enzymes (serum transaminases and alkaline phosphatase) have been observed; haemolytic anaemia has also been reported in rare cases.

Pharmaceutical precautions Merital 50 and Merital 25 Capsules should be stored in a cool, dry place in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Merital 50 is available in blister strips packed in cartons of 100 capsules.

Merital 25 is available in blister strips packed in cartons of 100 capsules. Merital AM is available in blister strips packed in cartons of 30 and 100 tablets.

Further information Nil.

Alcon

ADSORBOTEAR*

Presentation A sterile, clear, colourless, buffered, isotonic, ophthalmic drop containing polyvinylpyrrolidone 1.5%, macrogol 0.2%, hydroxyethylcellulose 0.44%, and preserved with thiomersal 0.002% and disodium edetate 0.05%.

Clinical use For dry eyes or where tears are absent or inadequate due to congenital or acquired conditions.

For use in dry eyes, especially where there is a defect in mucus production after erythema multiforme, chemical injuries and cicatrizing disease.

Dosage and administration Apply 1 or 2 drops to the eye(s) 3 times a day or as needed.

Contra-indications, warnings, etc Known sensitivity to any ingredient. If discomfort or irritation persists, discontinue use.

Warning: Do not touch the dropper tip as this may contaminate the solution.

Pharmaceutical precautions Keep the container tightly closed. Keep in a cool place, and out of the reach of children.

Legal category P.

Package quantities 10 ml.

Further information Nil.

Product licence number 3447/0004.

ALCOMICIN*

Presentation Alcomicin is a sterile, clear, colourless to slightly straw coloured solution for use as eye drops, and packed in 5 ml Drop-Tainers. It contains Gentamicin Sulphate equivalent to 0.3% w/v or 3 mg/ml of Gentamicin base, as a sterile, aqueous, isotonic, buffered solution preserved with 0.01% benzalkonium chloride.

Clinical use Alcomicin (gentamicin) is a bactericidal antibiotic with a broad spectrum of activity against the Gram-negative and Gram-positive bacteria, and its use is indicated in the treatment of external ocular infections caused by eye wounds, bacterial infection, acute conjunctivitis, dacryocystitis, corneal ulcers, blepharitis, keratitis and infections following surgery.

Dosage and administration 1 or 2 drops instilled topically into the conjunctival sac every 4 hours or as necessary.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any of its ingredients.

Precautions: Prolonged use of antibiotics may occasionally result in overgrowth of non-susceptible organisms, including fungi. If new infections appear during treatment

the drops should be discontinued and appropriate measures taken.

Adverse reactions: Occasional transient irritation may occur.

Warning: Alcomicin Ophthalmic Solution is not for injection.

Pharmaceutical precautions Store away from heat. Do not freeze. Keep the container tightly closed, and out of the reach of children. Discard contents one month after opening.

Legal category POM.

Package quantities 5 ml in Drop-Tainer dispensers.

Further information Alcomocin (gentamicin) eye drops are contained in an unbreakable semi-rigid plastic dropper bottle with a screw-on cap, and containing 5 ml of the preparation.

Product licence number 0649/0040.

BALANCED SALT SOLUTION ALCON BSS*

Presentation A sterile physiological balanced salt solution which is isotonic to the tissues of the eye. It is a lint free solution containing essential ions for normal cell metabolism. Each ml contains Sodium Chloride 0.49%, Potassium Chloride 0.075%, Calcium Chloride 0.048%, Magnesium Chloride Hexahydrate 0.030%, Sodium Acetate 0.39%, Sodium Citrate 0.17% and Water for Injection.

Clinical use As a physiologic irrigating solution.

Dosage and administration Sufficient to produce the required irrigation. The adaptor plug is designed to accept an ophthalmic irrigating needle. Intra-ocular tissue may be irrigated by attaching the needle to the Steri-Unit Drop-Tainer Bottle as follows:

1. Aseptically remove the Drop-Tainer by peeling off the paper backing.
2. Snap on surgical irrigator needle. Push well to ensure it is firmly in place.
3. Test patency of the assembly before inserting into the eye. External irrigation may be performed without the irrigating needle.

Contra-indications, warnings, etc

Contra-indication: There are no specific contra-indications for this product.

Warning: If the blister or paper backing is damaged or broken sterility of the enclosed bottle cannot be assured. Open under aseptic conditions only.

Pharmaceutical precautions This solution contains no preservative and should not be re-used. Prior to intra-ocular use check the following: tip should be firmly in place, irrigating needle should be properly seated. Squeeze out several drops before inserting into the

anterior chamber. The needle should be removed from the anterior chamber prior to releasing pressure to prevent suction.

Storage: Store under normal conditions at 46° to 75°F. The enclosed Steri-Unit Drop-Tainers are sterile and may be safely handled by the surgeon.

Legal category P.

Package quantities 15 ml Steri-Unit Drop-Tainer dispenser.

Further information Nil.

Product licence number 0649/0007.

DENDRID*

Presentation Idoxuridine 0.1% in a sterile buffered isotonic, ophthalmic solution, preserved with benzalkonium chloride 0.01%.

Clinical use For Herpes simplex infections of the eye.

Dosage and administration To be instilled into the affected eye every hour during the day, with continued application every two hours during the night until the lesion does not stain; then every two hours during the day and once at night for an additional 5-7 days.

N.B. Since idoxuridine interferes with the metabolic processes of the virus, only its continued presence can ensure therapeutic effectiveness. Therefore, it is important that a rigid administration schedule be utilized in order to obtain the desired results. Recurrences may occur if therapy is not continued for at least 5-7 days beyond the apparent healing time. If improvement is not obtained within 4-5 days other forms of therapy should be considered for concurrent use.

Contra-indications, warnings, etc There are no specific contra-indications. Some individuals may be sensitive to one or more of the components of this preparation. If any reaction occurs which is uncontrollable with anti-allergic therapy, treatment should be discontinued. Some individuals have experienced irritation or burning from the application of this drug; however, clinical response was not significantly altered in these cases. Care needs to be exercised when steroids are administered concurrently. This product contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pregnancy Warning: It has been reported that idoxuridine has teratogenic effects on animals when instilled into the eye. Therefore it should be administered with caution in pregnancy or in women with child-bearing potential.

Adverse reactions: Acute ocular irritation including burning, corneal stippling and clouding has been reported. Following prolonged use of Idoxuridine, ocular irritation characterised by follicular conjunctivitis, blepharitis with punctal swelling, bulbar conjunctival hyperemia, and corneal epithelial staining has also been reported. In either case, the drug should be discontinued.

Precautions: For topical use only. Do not exceed the frequency or duration of recommended dosage. Idoxuridine is not effective in corneal inflammations following herpes simplex keratitis in which the virus is not present. Some strains of herpes simplex appear resistant to the action of Idoxuridine.

Pharmaceutical precautions Store between 3 to 25° C. Protect from light. The contents should be discarded one month after opening. Keep out of reach of children.

Further information The preservative system in Dendrid has been improved so that it is no longer necessary to store the product in a refrigerator. It has also been possible to use the convenient opaque plastic white Drop-Tainer dispenser with the dropper nozzle, instead of the amber glass bottle.

Legal category POM.

Package quantities 15 ml white opaque plastic Droptainer.

Further information Nil.

Product licence number 0649/5910.

ISOPTO* ALKALINE

Presentation Isopto Alkaline is a sterile clear, colourless solution containing hydroxypropyl methylcellulose (hypromellose) 1.0%, preserved with benzalkonium chloride 0.01%.

Clinical uses Isopto Alkaline is an emollient solution used as a physiologic ophthalmic vehicle or suspending agent, and as a tear replacement in tear deficiency, Keratoconjunctivitis sicca and for ocular lubrication.

Dosage and administration It is suitable for use both by adults and children. The dose depends upon the desired amount of lubrication, the usual dosage being one or two drops to be instilled into the eyes three times daily, or as needed.

Contra-indications, warnings, etc If an irritation persists or increases use of the drops should be discontinued. In order to help preserve sterility the dropper should not be allowed to touch the eyelashes or any other surface. This product contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pharmaceutical precautions The eyedrops should be stored in a cool place (8° to 25°C). Keep out of reach of children. Discard one month after opening.

Legal category P.

Package quantities 10 ml containers.

Further information Isopto Alkaline eye-drops are contained in an unbreakable semi-rigid plastic dropper bottle with a screw-on cap, containing 15 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer.

Product licence number 0649/5900.

ISOPTO* ATROPINE 1.0%

Presentation Atropine sulphate U.S.P. 1.0% in the Isopto vehicle of hydroxypropyl methylcellulose (hypromellose) 0.5%. A sterile, isotonic, ophthalmic solution, preserved with benzalkonium chloride 0.01%.

Clinical uses Atropine is a powerful mydriatic and cycloplegic. It is used in refraction, especially in children, and in uveitis.

Dosage and administration For uveitis - one drop to be instilled into the eye three times daily. For refraction - one drop to be instilled into the eye twice daily for one or two days before examination and one hour before examination. In young children maintain pressure over lacrimal sac occluding lacrimal duct for one minute after instillation.

Contra-indications, warnings, etc This preparation is for ophthalmic use only. It should not be used in individuals with hypersensitivity to belladonna alkaloids, or with glaucoma. Prolonged use may produce local irritation and excessive use in children or in certain individuals may produce systemic symptoms of atropine poisoning.

Treatment of overdose: Physostigmine salicylate 1 or 2 mg subcutaneously to control the central or peripheral effects of atropine. This injection may need repeating every 1 or 2 hours as necessary.

Excitement may be controlled by small doses of short acting barbiturate, e.g. thiopentone sodium 100 mg.

Additional warning: This product contains benzalkonium chloride and should not be used when soft contact lenses are worn.

Pharmaceutical precautions Isopto Atropine should be stored in a cool place away from direct sunlight. Keep the container tightly closed. The contents should be discarded one month after opening.

Legal category POM.

Package quantities 5 ml containers.

Further information Isopto Atropine eye drops are contained in an unbreakable semi-rigid, plastic dropper bottle with screw-on cap, containing 5 ml of the preparation. This container bears the label and is in a rigid capped plastic outer.

Product licence number 0649/5901.

ISOPTO* CARBACHOL 3%

Presentation Isopto Carbachol is a clear colourless sterile solution, containing 3% Carbachol and 1% hydroxypropyl methylcellulose (hypromellose), and preserved with benzalkonium chloride 0.005%.

Clinical uses To reduce intraocular pressure. May be used to control intraocular pressure where control by pilocarpine has been lost or in cases of pilocarpine sensitivity.

Dosage and administration *Route of Administration:* Topical ocular use.

Recommended Dosage: Isopto Carbachol is suitable for use only in adults at a dose of two drops three times daily.

Contra-indications, warnings, etc Overdosage may cause systemic symptoms of anticholinesterase poisoning. Use with care in corneal abrasion. Contra-indicated where constriction is undesirable. This product contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Treatment of overdose: Atropine sulphate 1 or 2 mg subcutaneously or i.m. to control muscarine like effects; repeating the dose every 2-4 hours if necessary. Convulsions may be controlled with a short acting

barbiturate; muscle twitching with tubocurarine (oxygen may be necessary).

Pharmaceutical precautions Isopto Carbachol eye drops should be stored in a cool place away from direct sunlight. Keep the container tightly closed. Contents should be discarded one month after opening.

Legal category POM.

Package quantities 10 ml containers.

Further information Isopto Carbachol eye drops are contained in an unbreakable semi-rigid plastic dropper bottle with screw-on cap, containing 15 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer.

Product licence number 0649/5902.

ISOPTO* CARPINE

0.5%, 1.0%, 2.0%, 3.0%, 4.0%

Presentation Contains Pilocarpine hydrochloride USP in the following concentrations: 0.5%, 1.0%, 2.0%, 3.0% and 4.0%. The vehicle is a sterile, isotonic, ophthalmic solution containing hydroxypropyl methylcellulose (hypromellose) 0.5%, and preserved with benzalkonium chloride 0.01%.

Clinical uses Isopto Carpine is a miotic and its main use is in the treatment of glaucoma.

Dosage and administration Two drops to be instilled into the eye three times daily or as prescribed.

Contra-indications, warnings, etc Isopto Carpine is contra-indicated where constriction is undesirable such as in acute iritis. There are no known side effects except slight ciliary spasms with resultant temporary reduction of visual acuity. Sensitivity is infrequently observed. If reaction occurs discontinue use.

Side effects from eye-drops are usually controlled by reducing dosage and compressing the lacrimal sac for 5 minutes after each instillation. This product contains benzalkonium chloride and should not be used when soft contact lenses are worn.

Isopto Carpine should be stored in a cool place away from direct sunlight. Keep the container tightly closed. The contents should be discarded one month after opening.

Legal category POM.

Package quantities 10 ml containers.

Further information Isopto Carpine eye drops are contained in an unbreakable semi-rigid, plastic dropper bottle with screw-on cap, containing 15 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer.

ISOPTO* CETAMIDE 15%

Presentation Isopto Cetamide is a clear, colourless sterile solution, of 0.5% tetrahydroxypropyl methylcellulose

(hypromellose) containing Sulphacetamide Sodium 15%, and preserved with methylparaben 0.05% and propylparaben 0.01%.

Clinical uses As an anti-infective.

Dosage and administration *Route of Administration:* Topical ocular use.

Recommended Dosage: Acute infection: two drops every 2 hours or as prescribed.

Chronic Infections: two drops every 4 hours or as prescribed. Isopto Cetamide is suitable for use by both adults and children.

Contra-indications, warnings, etc Should not be used on patients who have shown hypersensitivity to sulphonamides.

Pharmaceutical precautions Isopto Cetamide eye drops should be stored in a cool place away from direct sunlight. Keep the container tightly closed. Contents should be discarded one month after opening.

Legal category POM.

Package quantities 15 ml.

Further information Isopto Cetamide eye drops are contained in an unbreakable semi-rigid container. This container bears the label and is itself in a rigid capped plastic outer.

Product licence number 0649/5909.

ISOPTO* EPINAL 0.5% and 1.0%

Presentation Isopto Epinal is a clear, colourless to light yellow, sterile, aqueous solution containing 0.5% or 1% Adrenaline, (as the borate complex). Hydroxypropyl methylcellulose (hypromellose), and preserved with benzalkonium chloride 0.01%.

Clinical uses Isopto Epinal is indicated for the control of simple open angle glaucoma. It may be used with miotics. Carbonic Acid Anhydrase inhibitors may be used with this drug in selected cases.

Dosage and administration *Route of Administration:* Instillation into the eye(s).

Recommended Dosage: The dosage must be adjusted to tonometric readings before and during therapy. The usual dosage is one drop in the eye(s) once or twice daily. When used to complement miotic therapy this drug should be instilled 5 to 10 minutes after the miotic drug.

Contra-indications, warnings, etc Do not use in narrow angle glaucoma. Do not use until the diagnosis of glaucoma has been verified. For ophthalmic use only. Not for injection.

Treatment of severe reaction: A severe reaction to adrenaline is rapid in onset and of short duration. In such an event give individuals I.V. injection of quick acting α -adrenergic blocking agent such as 5 to 10 mg pentolamine mesylate, followed by a β -blocking agent such as 2.5 to 5 mg propranolol.

Adverse Reactions: Isopto Epinal drops should be used with caution in patients with hypertensive cardiovascular disease. Prolonged use may produce extra-cellular pigmentation. On rare occasions systemic side-effects have been observed such as headaches, palpitation, pallor, tachycardia, trembling and perspiration. Stinging

may occur after instillation with rebound redness. This product contains benzalkonium chloride and should not be used when soft contact lenses are worn.

Pharmaceutical precautions Contents should be discarded one month after opening. After dispensing, the patient is advised to observe the following precautions:

1. Store the bottle in an up-right position with the dropper tightly sealed.
2. Protect from excessive heat and light. Keep in a cool, dark place.
3. Prevent the dropper tip from touching the eye-lid or other surfaces since this may contaminate the solution. Do not rinse the dropper in tap water.
4. If the clear solution changes colour, obtain a fresh supply from the pharmacist.

Legal category P.

Package quantities 7.5 ml amber glass bottles with dropper.

Further information Nil.

Product licence numbers

1% 0649/0001
0.5% 0649/0002

ISOPTO* FRIN 0.12%

Presentation Isopto Frin is a clear, colourless sterile solution, containing Phenylephrine Hydrochloride 0.12% in a hydroxypropyl methylcellulose (hypromellose) 0.5% aqueous base, preserved with benzalkonium chloride 0.01%.

Clinical uses As an emollient lubricant with vasoconstrictive effect.

Dosage and administration *Route of Administration:* Topical ocular use.

Recommended Dosage: Isopto Frin is suitable for use by both adults and children. One or two drops three times a day or as necessary.

Contra-indications, warnings, etc If the irritation persists or increases its use should be discontinued. Slight dilation of the pupil may occur in some patients. For this reason it should be used with care where narrow angle glaucoma may be present, since its use may precipitate angle closure, or in those with a shallow anterior chamber. This packet contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pregnancy Warning: This product should only be used during pregnancy if considered essential by the physician.

Precautions: Care should be exercised in its use in small children, pressure should be put on the inner canthus of the eye for a few minutes after instillation to decrease systemic absorption via the naso lacrimal duct.

Use with caution on an inflamed eye, as hyperaemia greatly increases the rate of systemic absorption through the conjunctiva.

Pharmaceutical precautions Isopto Frin eye drops should be stored in a cool place away from direct sunlight. Keep the container tightly closed. Contents should be discarded one month after opening.

Legal category P.

Package quantities 10 ml containers.

Further information Isopto Frin eye drops are contained in an unbreakable semi-rigid plastic dropper bottle with a screw-on cap, containing 15 ml of the preparation.

Product licence number 0649/5911.

ISOPTO* PLAIN

Presentation Isopto Plain is a sterile, clear, colourless solution containing hydroxypropyl methylcellulose (hypromellose) 0.5%, and preserved with benzalkonium chloride 0.01%.

Clinical uses Isopto Plain is a soothing emollient solution used in cases of tear deficiency as a lubricant, and as an artificial tear and may be used with hard contact lenses.

Dosage and administration It is suitable for use both by adults and children. The dose is one or two drops topically instilled into the eyes three times daily as needed, or as prescribed by the doctor.

Contra-indications, warnings, etc If an irritation persists or increases, use of the drops should be discontinued. In order to help preserve sterility the dropper should not be allowed to touch the eyelids or any other surface. This product contains benzalkonium chloride, and should not be used when soft contact lenses are being worn.

Pharmaceutical precautions The eye-drops should be stored in a cool place (8° to 25°C). Keep the container tightly closed. Keep out of reach of children. Discard contents one month after opening.

Legal category P.

Package quantities 10 ml containers.

Further information Isopto Plain eye-drops are contained in an unbreakable semi-rigid plastic dropper bottle with a screw-on cap, containing 15 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer.

Product licence number 0649/5920.

MAXIDEX*

Presentation Dexamethasone 0.1% in a vehicle containing 0.5% hydroxypropyl methylcellulose (hypromellose). A sterile, isotonic, ophthalmic suspension, preserved with benzalkonium chloride 0.01%.

Clinical uses Maxidex is indicated in the treatment of certain inflammatory conditions of the anterior segment. Acute and chronic anterior uveitis, iritis, iridocyclitis, cyclitis, herpes zoster ophthalmicus. External diseases: non specific superficial keratitis, phytotenular keratoconjunctivitis, vernal conjunctivitis, allergic, catarrhal and non purulent conjunctivitis.

Recurrent marginal ulceration of toxic or allergic aetiology. Thermal or chemical burns. Post-operatively to reduce inflammatory reactions.

Dosage and administration For severe to acute inflammations 1 or 2 drops to be instilled into the eye every 30-60 mins. for at least 3-4 days or until a satisfactory response is made. Then every 2 to 3 hours

for one to two weeks. If a favourable response is not obtained in 3-4 days subconjunctival or systemic therapy should be instituted.

Contra-indications, warnings, etc

Contra-indications: Herpes simplex and other viral diseases of the cornea and conjunctiva. Fungal disease. Tuberculosis and acute purulent untreated infections.

Warnings: Extended use of topical steroids may increase intraocular pressure which should be checked frequently. In those diseases causing thinning of the cornea, perforation has been known to occur with the use of topical steroids. If the inflammation does not respond within a reasonable period other forms of therapy should be instituted. If any reaction indicating sensitivity is observed, discontinue use. In cases of bacterial infections concomitant use of antibiotics or chemotherapeutics is mandatory.

Intensive or prolonged topical corticosteroid therapy is a possible factor in the formation of posterior subcapsular cataracts. This product contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pregnancy Warning: Although topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use in pregnancy has not been absolutely established, therefore it is advisable not to use this product for long term treatment of pregnant patients.

Pharmaceutical precautions Maxidex should be stored in a cool place away from direct sunlight. Keep the container tightly closed. The contents should be discarded one month after opening. Shake well before using.

Legal category POM.

Package quantities 10 ml and 15 ml containers.

Further information Maxidex eye drops are contained in an unbreakable semi-rigid, plastic dropper bottle with a screw-on cap, containing 5 ml or 15 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer. Maxidex is a highly penetrating form of dexamethasone, a 0.1% microfine suspension especially formulated to provide maximum corneal absorption.

Product licence number 0649/5914.

MAXITROL* EYE DROPS MAXITROL* EYE-OINTMENT

Presentation Drops: Dexamethasone BP 0.1% Polymyxin B Sulphate USP 6,000 units/ml and Neomycin Sulphate equivalent to Neomycin 3.5 mg/ml in a vehicle containing 0.5% hydroxypropyl methylcellulose (hypromellose). A sterile, isotonic, ophthalmic suspension, preserved with benzalkonium chloride 0.004%.

Ointment: Dexamethasone BP 0.1% Polymyxin B Sulphate USP 6,000 units/g and Neomycin Sulphate equivalent to Neomycin 3.5 mg/g in an ointment base, preserved with methylparaben 0.05% and propylparaben 0.01%.

Clinical uses Management of infectious ocular inflammations produced by organisms which are sensitive to Neomycin Sulphate and Polymyxin B Sulphate.

Acute or chronic non-purulent conjunctivitis, blepharo-conjunctivitis, kerato-conjunctivitis, non-specific superficial keratitis, deep keratitis, and acne rosacea keratitis, herpes zoster ophthalmicus iridocyclitis, mild acute iritis, recurrent marginal ulceration, corneal ulcer, non-purulent blepharitis, scleritis, episcleritis and sclero-conjunctivitis. Post-operatively to prevent ocular infection.

Dosage and administration *Drops:* One or two drops to be instilled into the conjunctival sac, 4-6 times daily. Dosage may be reduced after 3-4 days when a satisfactory response has been obtained.

Ointment: Apply a small amount of ointment into the conjunctival sac, 3-6 times a day. When a favourable response is observed, the dosage may be reduced to 3-4 applications per day. This may be followed by once a day applications for several more days.

Contra-indications, warnings, etc

Contra-indications: This drug is contra-indicated in tuberculous, fungal and most viral lesions of the eye (herpes simplex/dendritic keratitis); vaccinia; varicella; acute purulent conjunctivitis and acute purulent blepharitis; and in those persons who have shown hypersensitivity to any of its components.

Warnings: Extended use of topical therapy may cause increased intraocular pressure in certain individuals. It is advisable that intraocular pressure be checked frequently. In those diseases causing thinning of the cornea, perforation has been known to occur with the use of topical steroids.

Prolonged use may result in overgrowth of non-susceptible organisms, including fungi. If the condition does not respond within a reasonable period other forms of therapy should be instituted.

Appropriate measures should be taken when this occurs. A few individuals may be sensitive to one or more components of this product. If any reactions indicating sensitivity are observed discontinue use. Extended use of topical steroids is a possible factor in the formation of subcapsular cataracts. Maxitrol drops contain benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pregnancy Warning: Although topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use in pregnancy has not been absolutely established, therefore it is advisable not to use this product for long term treatment of pregnant patients.

Pharmaceutical precautions Maxitrol eye-drops and eye-ointment should be stored in a cool place away from direct sunlight. Keep the container tightly closed. Contents should be discarded one month after opening. Drops should be well shaken before use.

Legal category POM.

Package quantities *Drops:* 5 ml container
Ointment: 3.5 g

Further information *Drops:* Maxitrol eye-drops are contained in an unbreakable semi-rigid, plastic dropper bottle with screw-on cap, containing 5 ml of the preparation. This container bears the label and is itself in a rigid capped plastic outer.

Ointment: Maxitrol eye-ointment is contained in a tube with a screw-on cap. This tube bears the label and is itself in a rigid capped plastic outer.

Maxitrol Eye-Drops 0649/5915
Maxitrol Eye-Ointment 0649/5916

MYDRIACYL 0.5% w/v and 1.0% w/v

Presentation Mydriacyl is a sterile clear, colourless solution containing Tropicamide 0.5% w/v or 1.0% w/v, packed in 5 ml Droptainers, and preserved with benzalkonium chloride 0.01%.

Clinical use As a mydriatic and cycloplegic.

Dosage and administration *Topically:* For refraction, 1 or 2 drops of 1.0% solution in the eye(s), repeated in 5 minutes. If patient is not seen within 20 to 30 minutes, an additional drop may be instilled to prolong mydriatic effect. For examination of fundus, 1 or 2 drops of 0.5% solution 15 or 20 minutes prior to examination.

Contra-indications, warnings, etc

Contra-indications: The use of Mydriacyl in narrow angle glaucoma is contraindicated as it may precipitate angle closure.

Warnings: This preparation may cause CNS disturbances, and care should be exercised in its use in infants and small children. Pressure should be put on the inner canthus of the eye for a few minutes after the instillation to decrease systemic absorption via the naso lacrimal duct.

The possibility of the occurrence of psychotic reaction and behavioural disturbance due to hypersensitivity to anticholinergic drugs should be borne in mind. This product contains benzalkonium chloride and should not be used where soft contact lenses are being worn.

Pregnancy Warning: There is no evidence as to the drug safety in human pregnancy, nor is there evidence from animal work that it is free from hazard. This product should only be used during pregnancy if considered essential by the physician.

Precautions: In the elderly and others where increased intra-ocular pressure may be encountered, mydriatics and cycloplegics should be used cautiously. To avoid inducing angle closure glaucoma, an estimation of the depth of the angle of the anterior chamber should be made.

The lacrimal sac should be compressed by digital pressure for 1 minute after instillation to avoid excessive systemic absorption.

Use with caution on an inflamed eye, as hyperaemia greatly increases the rate of systemic absorption through the conjunctiva.

Adverse Reactions: Increased intra-ocular pressure. Psychotic reactions, behavioural disturbances, and cardiorespiratory collapse in children with this class of drugs has been reported.

Transient stinging, dryness of the mouth, blurred vision, photophobia with or without corneal staining, tachycardia, headache, parasympathetic stimulation or allergic reaction may occur.

Treatment of Severe Reaction: A severe reaction to tropicamide is rapid in onset and of short duration. In such an event give immediate I.V. injection of quick acting α -adrenergic blocking agent such as 5 to 10 mg pentolamine mesylate, followed by a β -blocking agent such as 2.5 mg of propranolol.

Pharmaceutical precautions Mydriacyl eye drops should be stored in a cool place, away from direct

sunlight, but do not refrigerate. Keep the container tightly closed. Discard one month after opening.

Legal category POM.

Package quantities 5 ml containers.

Further information Mydriacyl eye drops are contained in a semi-rigid plastic dropper bottle with a screw-on cap.

Product licence numbers 0649/5917
0649/5918

ALCON OPULETS* ATROPINE 1%

Presentation Single dose clear, colourless, sterile eye drops containing 1% w/v of atropine sulphate BP.

Clinical uses Mydriatic and cycloplegic.

Atropine is used both pre-operatively and post-operatively and may also be used in the treatment of keratitis, iritis and cyclitis, and in refractive work in children.

Dosage and administration One drop as required. Dilatation of the pupil occurs within half an hour on local application.

Uveitis: two of three drops to be instilled four hourly initially and reducing to twice daily when pupil is dilated.

Refraction: two or three drops to be instilled two or three times daily prior to examination.

Contra-indications, warnings, etc Because of the irreversible mydriasis produced by atropine there is a risk that it may precipitate an acute glaucoma episode in cases of latent narrow angle glaucoma. If there is any doubt, the weaker homatropine should be used since its action is reversible by eserine or pilocarpine.

Pharmaceutical precautions Alcon Opulets should be stored in a cool place and protected from strong light.

Legal category POM.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information Nil.

Product licence number 0649/0061

ALCON OPULETS* BENOXINATE

Presentation Single dose, clear, colourless sterile eye drops containing 0.4% w/v oxybuprocaine hydrochloride (Benoxinate).

Clinical uses Local anaesthetic.

Dosage and administration One drop.

Benoxinate is less irritant than amethocaine in similar concentrations.

Tonometry: One drop is sufficient to anaesthetise the surface of the eye to allow tonometry after 60 seconds.

Fitting Contact Lenses: A further drop after 90 seconds provides adequate anaesthesia for the fitting of contact lenses.

Removal of Foreign Body and/or Incision of Meibomian Cyst: Three drops at 90 second intervals provides sufficient anaesthesia after five minutes for a foreign body to be removed from the corneal epithelium or incision of a Meibomian cyst through the conjunctival

surface. Corneal sensitivity is normal again after about one hour.

Children: Dosage is at the discretion of the physician.

Contra-indications, warnings, etc The anaesthetised eye should be protected from dust and bacterial contamination. Prolonged application of anaesthetic eye drops may damage the cornea.

Pharmaceutical precautions Alcon Opulets should be stored in a cool place and protected from strong light. Solutions of Benoxinate and fluorescein sodium should not be mixed as a precipitate may be formed.

Legal category POM.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information Benoxinate produces very little conjunctival irritation or hyperaemia and has no effect on the pupil.

The sensitivity of the cornea returns to normal about one hour after administration of Benoxinate drops.

Product licence number 0649/0056.

ALCON OPULETS* CHLORAMPHENICOL 0.5%

Presentation Single dose, clear, colourless, sterile eye drops containing 0.5% w/v Chloramphenicol BP.

Clinical uses Chloramphenicol is a broad spectrum bacteriostatic antibiotic effective against a wide range of Gram negative and Gram positive organisms.

Dosage and administration *Adult:* One or more drops as required.

Children: One drop as required.

Contra-indications, warnings, etc Treatment should be discontinued on the appearance of toxic symptoms or allergic skin rashes. Such a general allergy should be treated with antihistamines by mouth.

Pharmaceutical precautions Alcon Opulets containing Chloramphenicol should be stored at 5°C and away from strong light.

Legal category POM.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information Nil.

Product licence number 0649/0047.

ALCON OPULETS* CYCLOPENTOLATE 1%

Presentation Single dose, clear, colourless, sterile eye drops containing 1% w/v cyclopentolate hydrochloride BP.

Clinical uses Mydriatic and cycloplegic.

Dosage and administration One or two drops as required.

Maximum effect achieved 30–60 minutes after instillation.

Contra-indications, warnings, etc Recovery of accommodation occurs within 24 hours but may be achieved more rapidly if 1 or 2 drops of a 2% w/v solution of pilocarpine nitrate are instilled.

Use may precipitate a case of latent narrow angle glaucoma into an acute attack.

Pharmaceutical precautions Alcon Opulets should be stored in a cool place and should not be exposed to strong light.

Legal category POM.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information Nil.

Product licence number 0649/0058.

ALCON OPULETS* FLUORESCEIN SODIUM 1%

Presentation Single dose, clear orange/red sterile solution of 1% w/v fluorescein sodium BP.

Clinical uses As a diagnostic stain. Fluorescein does not stain the normal cornea.

Corneal and conjunctival abrasions or ulcers are stained a bright green and foreign bodies are surrounded by a green ring.

Dosage and administration Sufficient solution should be applied to stain the damaged areas. Excess solution may be washed away with sterile saline solution.

Contra-indications, warnings, etc Special care should be taken to avoid bacterial contamination.

Pharmaceutical precautions Alcon Opulets should be stored in a cool place and not exposed to strong light.

Legal category P.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information The use of single dose contained preparations of fluorescein sodium are to be preferred according to Martindale (Extra Pharmacopoeia).

Product licence number 0649/0048.

ALCON OPULETS* SODIUM CHLORIDE

Presentation Single dose, clear, colourless, sterile eye drops containing 0.9% w/v sodium chloride BP.

Clinical uses Irrigating agent for the eye.

Dosage and administration Use sufficient solution to adequately irrigate the eye.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Alcon Opulets should be stored in a cool place and should not be exposed to strong light.

Legal category P.

Package quantities Alcon Opulets are available in packs of 20 units each containing 0.25 ml.

Further information Nil.

Product licence number 0649/0055.

ORATROL* TABLETS

Presentation White, circular, bi-convex tablets with a breakline, each containing 50 mg Dichlorphenamide USP.

Uses For adjunctive treatment of chronic simple (open-angle) glaucoma, secondary glaucoma, and preoperatively in acute angle closure glaucoma where delay of surgery is desired in order to lower intraocular pressure.

Oratrol is an orally effective carbonic anhydrase inhibitor. Renal excretion of sodium, potassium and bicarbonate is increased, resulting in an alkaline urine. It also causes a definite increase in chloride excretion. This enhanced excretion of chloride explains at least in part the continued efficacy of Oratrol with repeated administration and the lesser possibility for the development of metabolic acidosis. As is the case with all carbonic anhydrase inhibitors, dichlorphenamide, in high doses, causes some decrease in renal blood flow and glomerular filtration rate.

Oratrol administered orally reduces intraocular pressure by inhibiting the formation of aqueous humour in normal as well as in glaucomatous eyes. The onset of action following a single dose is within an hour and maximal effect is observed within 2 to 4 hours. The reduced intraocular pressure may be maintained for approximately 6 to 12 hours.

Oratrol therapy is most successful, when employed in conjunction with miotics.

Dosage and administration Must be adjusted carefully to meet the requirements of the individual patient. A priming dose of 100 to 200 mg (2 to 4 tablets) is suggested to be administered to adults followed by 100 mg (2 tablets) every 12 hours until the desired response has been obtained. For maintenance therapy dichlorphenamide may be administered to adults in a dosage of 25 to 50 mg ($\frac{1}{2}$ to 1 tablet) one to three times daily.

Contra-indications, warnings, etc

Contra-indications: Hepatic insufficiency, renal failure, hyperchloremic acidosis, adrenocortical insufficiency.

Pregnancy Warning: Dichlorphenamide has caused birth anomalies in experimental animals; therefore, it should be used in pregnant patients or in women of child bearing age only when, in the judgement of the physician, its use is deemed essential to the welfare of the patient.

Warning: Cases with extensive peripheral anterior synechiae and marked impairment of outflow, i.e., haemorrhagic glaucoma, respond very poorly to secondary inhibitors.

Precautions: A close check on the electrolyte balance of the patient is essential during therapy with dichlorphenamide as with patients on any other carbonic anhydrase inhibitor type of compound. In the presence of pulmonary infection where there is severe loss of pulmonary ventilation, therapy with dichlorphenamide should be employed cautiously. Blood counts should be taken regularly to determine the possibility of agranulocytosis or thrombocytopenia.

Adverse Reactions: Side effects which will occur particularly in the high dosage range include gastrointestinal disturbances (anorexia, nausea and vomiting), nervousness, globus hystericus, lassitude, ataxia, tremor, tinnitus, paresthesia (numbness and tingling) of the hands, feet, tongue, mild skin eruption, pruritus, agranulocytosis, and thrombocytopenia. Renal calculi may occur.

Treatment of overdose: The stomach should be emptied by emesis or gastric lavage. Fluids and electrolytes should, if necessary, be replenished. The most likely electrolyte disturbance is a hyperchloraemic acidosis that may respond to bicarbonate administration.

Pharmaceutical precautions Keep out of reach of children.

Legal category POM.

Package quantities 100 tablets.

Further information The product is supplied in 'blister pack' strips each containing 25 tablets, and 4 strips to a carton, it is also packed in amber screw capped tablet bottles.

Product licence number 0649/5919.

TEARS Naturale*

Presentation Tears Naturale is a clear, colourless sterile solution, presented in a 15 ml Drop-Tainer Dispenser, and contains the Duasorb water soluble polymeric system Dextran 70 USP 0.1% and Hydroxypropyl Methylcellulose (Hypromellose 0.3%), and preserved with benzalkonium chloride 0.01% and disodium edetate 0.05%.

Clinical uses A soothing solution for use as an artificial tear and lubricant in the relief of dry eye syndromes associated with deficient tear secretion or deficient mucous.

Dosage and administration Instill 1 or 2 drops into the eye(s), as frequently as to relieve eye irritation symptoms.

Contra-indications, warnings, etc

Contra-indications: This product contains benzalkonium chloride, and should not be used when soft contact lenses are being worn.

Precautions: If irritation persists, discontinue use.

Pharmaceutical precautions To avoid contaminating the solution, do not let the dropper tip touch any surface. Keep the container tightly closed. Discard the contents 1 month after opening.

Legal category P.

Package quantities 15 ml in a special dropper container.

Further information Tears Naturale eye-drops are contained in an unbreakable semi-rigid plastic dropper bottle with a screw-on cap, containing 15 ml of the preparation. The cap is secured to the container by a seal which is broken when first opened.

Product licence number 0649/0031.

ZINCIFRIN*

Presentation Zincfrin is a clear, colourless sterile solution containing Zinc Sulphate 0.25% w/v and Phenylephrine Hydrochloride 0.12% w/v, preserved with benzalkonium chloride 0.01% w/v.

Clinical uses For the treatment of mild, non-specific conjunctivitis, ocular irritation and allergies.

Dosage and administration *Route of Administration:* Topical ocular use.

Recommended Dosage: Zincfrin is suitable for use in both adults and children. 1 or 2 drops in the eyes 3 times daily for adults, and children or as directed by physician.

Contra-indications, warnings, etc If irritation per-

sists or increases the use of Zincfrin should be discontinued. It causes slight dilatation of the pupil and should be used with care in cases of narrow angle glaucoma, since its use may precipitate angle closure, or in those with a shallow anterior chamber.

This product contains benzalkonium chloride and should not be used when soft contact lenses are being worn.

Pregnancy Warning: This product should only be used during pregnancy if considered essential by the physician.

Precautions: Care should be exercised in its use in small children, pressure should be put on the inner canthus of the eye for a few minutes after instillation to decrease systemic absorption via the naso-lacrimal duct.

Use with caution on an inflamed eye, as hyperaemia greatly increases the rate of systemic absorption through the conjunctiva.

Pharmaceutical precautions Zincfrin eye drops should be stored in a cool place away from direct sunlight. Keep the container tightly closed. Discard contents one month after opening.

Legal category P.

Package quantities 15 ml containers.

Further information Zincfrin eye drops are contained in an unbreakable semi-rigid plastic dropper bottle with screw-on cap.

Product licence number 0649/5921.

ALCODERM* CREAM/LOTION

Presentation *Cream:* A white, thick smooth cream.

Lotion: A creamy white, smooth, viscous lotion.

Alcoderm contains liquid paraffin, purified water, cetylalcohol, stearyl alcohol, sodium lauryl sulphate, carbomer, polysorbate 60, triethanolamine, methylparaben, propylparaben.

Clinical use Dry, chafed or irritated skin – Alcoderm is indicated in any condition where the moisture content of the horny layer has decreased below the normal level and the skin is no longer soft and pliable.

Also recommended:

- in acute inflammatory conditions where the skin is intact, such as sunburn and windburn.
- as a smoothing, hydrating agent in certain inflammatory skin conditions where there is dryness and scaling, such as ichthyosis, atopic eczema, winter itch etc.
- as a vehicle for other active constituents.

Additional information: Alcoderm is a specially formulated emulsion with a double acting moisturizing effect. The lotion is suitable for large areas of skin, the cream for smaller drier areas. Alcoderm has a double moisturizing action which can be provided only by oil-in-water emulsions. It hydrates rapidly the surface layers of the skin, and at the same time the oil droplets form a thin, protective layer on the skin. This film gives Alcoderm its special characteristics; it is highly hydrostatic and protects the skin against excessive evaporation of the water. Only 0.6% of the film-forming surface active agents in Alcoderm are water-soluble. No other oil-in-water emulsion contains such a small quantity of water soluble ingredients.

Administration Apply topically to the skin. As required to alleviate the abovementioned skin conditions or as directed by a doctor.

Contra-indications, warnings, etc Avoid contact with the eyes.

Legal category P.

Package quantities

Cream: 60 g
Lotion: 120 ml

Further information Nil.

0649/0005 Lotion

DEBROXIDE*

Presentation Debroxide is a topical aqueous gel containing benzoyl peroxide 5%/10%, dioctyl sodium sulfosuccinate, ederate disodium, poloxamer 182, carbomer 940, propylene glycol, silicon dioxide, purified water, citric acid and/or sodium hydroxide to adjust pH.

Clinical use Debroxide is recommended for adjunctive topical treatment of acne vulgaris. Benzoyl peroxide is an established and effective keratolytic agent with antibacterial properties. It has been shown to be effective in reducing the local population of *Propionibacterium* acnes leading to a reduction in the production of irritant fatty acids in the sebaceous glands.

Administration After washing with a mild cleanser and water, apply once or twice daily to the affected area. The degree of drying and peeling can be adjusted by modification of the dosage schedule.

Contra-indications, warnings, etc

Contra-indication: Persons having known sensitivity to benzoyl peroxide.

Precaution: Avoid contact with the eyes, eyelids and other mucous surfaces.

Warning: May bleach hair and coloured fabrics.

FOR EXTERNAL USE ONLY.

Overdosage: Symptoms: The skin may become excessively red and sore during the first few days of treatment.

Treatment: Apply less often until this phase has passed.

Pharmaceutical precautions Store at room temperature.

Legal category P.

Package quantities Debroxide 5 – 60 g plastic tubes.

Debroxide 10 – 60 g plastic tubes.

Further information Nil.

Product licence numbers

Debroxide 5 0649/0051
Debroxide 10 0649/0062

IONAX* SCRUB

Presentation A pale yellow semi-translucent abradant gel with a fresh odour of lemon for external application. The active ingredients are polyethylene granules, benzalkonium chloride, macrogol (4) lauryl ether, macrogol

(23) lauryl ether, alcohol and foaming agents in an aqueous gel base.

Clinical use An abradant cleanser for the control and hygiene of acne. Use Ionax Scrub to cleanse skin prior to acne or oily skin treatment.

Administration Apply to wet face. Massage on the skin for one or two minutes, then rinse thoroughly.

Use once or twice daily, or as directed by your physician.

Contra-indications, warnings, etc **Caution:** Avoid contact with the eyes.

Upon accidental contact, flush with water and avoid rubbing.

If the skin gets too dry or too reddened discontinue use temporarily.

For external use only. Keep out of reach of children.

Pharmaceutical precautions There are no special pharmaceutical precautions.

Legal category P.

Package quantities 60 g packs in plastic collapsible tubes with plastic screw caps.

Further information Nil.

Product licence number 0649/0006.

IONIL T* SHAMPOO

Presentation A clear brown liquid shampoo with a slight odour of coal tar, for external use. It contains salicylic acid, benazalkonium chloride, coal tar solution USP 5% with polyoxyethylene ethers in an hydro-alcoholic shampoo base.

Clinical use For seborrhoeic dermatitis of the scalp.

Administration Massage Ionil T Shampoo into wet hair.

Do not expect much initial lather as the shampoo is formulated for low foaming.

Rinse, and then apply Ionil T shampoo again and massage into a lather. Allow to remain in the hair for about five minutes before rinsing.

This shampoo may be used daily or as directed by the physician.

For best results do not use soap, detergent or other shampoo on the hair immediately before or after using Ionil T.

Contra-indications, warnings, etc **Caution:** Avoid contact with the eyes.

Upon accidental contact, flush with clear water.

For external use only. Keep out of reach of children.

Pharmaceutical precautions Store away from internal preparations and foods.

Legal category P.

Package quantities 120 ml and 240 ml in cylindrical plastic containers with plastic screw caps.

Further information Nil.

Product licence number 0649/0003.

NUTRAPLUS* Cream

Presentation A smooth white, unperfumed cream for

topical external application. It contains 10% Urea, purified water, blend of light mineral oil, glyceryl monostearate, propylene glycol, methylparaben, propylparaben.

Clinical use An emollient, moisturising and protective cream for the treatment of dry or damaged skin. The presence of 10% urea in the product assists in providing a 'moisturising' effect lasting 5-6 hours, as shown by experiments measuring 'trans-epidermal water loss', in addition to providing the recognised actions of urea for dermatological purposes.

Dosage and administration Apply evenly to dry skin areas 2 to 3 times daily, or as necessary.

Contra-indications, warnings, etc If irritation occurs to any ingredient, discontinue use temporarily. Avoid contact with eyes.

Pharmaceutical precautions For external use only. Keep out of reach of children. Store in a cool place. Replace cap after use.

Legal category P.

Package quantities Nutraplus Cream 60 g.

Further information Nil.

Product licence number 0649/0041.

PSORIGEL*

Presentation A clear thin brown gel with a slight characteristic odour of tar, for topical external application. It contains Solution of coal tar USP 7.5%, 33% alcohol, carbomer 946, propylene glycol, ethanol, laureth 4, diisopropanolamine, and purified water. The hydroalcoholic gel base which is emollient, provides a moist film with the minimum of tar odour and staining potential.

Clinical use For the relief and treatment of inflammatory manifestations of tar responsive dermatoses. Among these are eczema, psoriasis, inflammation, erythema, scaling, pruritus and induration that accompanies various forms of dermatitis.

It also helps to relieve the itching that accompanies psoriasis, and eczema, and helps control the flaking and scaling as well.

Dosage and administration Rub into the affected areas once or twice daily. The gel may be applied more frequently if necessary.

Rub in well, allow to dry and remove any excess by patting with a paper tissue.

Contra-indications, warnings, etc *Caution:* Avoid contact with eyes. Upon accidental contact, flush with water.

After using, avoid exposure to direct sunlight, unless its action is specifically required.

Do not use on highly inflamed or broken skin.

The product contains alcohol.

If undue irritation develops, reduce the frequency of use, or suspend use until irritation subsides.

The staining potential of the product is minimal, but if it does occur, standard laundry procedure will remove most stains.

Pharmaceutical precautions For external use only. Keep out of reach of children.

Legal category P.

Package quantities 90 g in plastic collapsible tubes.

Further information Nil.

Product licence number 0649/0039.

AMINOGRAN* FOOD SUPPLEMENT

Presentation Aminogran Food Supplement provides a mixture of L-amino acids, including all the essential amino acids except phenylalanine. It is intended for use with Aminogran Mineral Mixture (see separate Data Sheet for Aminogran Mineral Mixture).

Content per 100 g = 1,675 kJ (400 calories)

	g	mmol
L-Alanine	2.44	27.4
L-Arginine (as glutamate)	4.20	24.1
L-Aspartic acid	6.10	45.8
L-Cystine	1.45	6.0
L-Glutamic acid (total)	12.19	82.9
Glycine	6.10	81.3
L-Histidine (as monohydrochloride)	3.40	21.9
L-Isoleucine	8.53	65.0
L-Leucine	9.95	75.9
L-Lysine (as glutamate)	6.61	45.2
L-Methionine	2.96	19.8
L-Proline	4.26	37.0
L-Serine	8.39	79.8
L-Threonine	5.71	47.9
L-Tryptophan	1.45	7.1
L-Tyrosine	6.42	35.4
L-Valine	7.01	59.8

Aminogran Food Supplement is packed as 500 g in a white polythene bag in a cylindrical plastic container with cardboard carton. The mixture is a white powder. A white measuring scoop is provided which contains 5 g when levelled with a knife edge.

Uses Aminogran Food Supplement is indicated in conjunction with Aminogran Mineral Mixture for the dietary management of phenylketonuria in infants and children, and in phenylketonuric women during pregnancy. It may be used for bottle feeding phenylketonuric infants, but if available, a preparation based on a low-phenylalanine protein hydrolysate is more practicable. Prior to weaning bottle feeds can more easily be prepared from a preparation based on a low-phenylalanine protein hydrolysate, together with carbohydrates and fats to supply energy requirements. Once weaning is started a gradual change to Aminogran should be made, as it proves more acceptable than the protein hydrolysate and reduces feeding problems.

Dosage and administration The aim of treatment with Aminogran preparations is to provide an adequate diet in which there is a reduced intake of phenylalanine so that the blood levels of this amino acid are maintained at 0.2–0.5 mmol/litre (3–8 mg/100 ml).

In sucklings this is best obtained with a preparation based on a low-phenylalanine protein hydrolysate as there are practical difficulties associated with the administration of Aminogran in bottle form due to its low energy value and high osmolality. However, once spoon-feeding is started Aminogran has the advantages of

smaller bulk and superior palatability. Aminogran Food Supplement and Aminogran Mineral Mixture can be used, in appropriately reduced dosage, in conjunction with low-phenylalanine protein hydrolysate during weaning. As the quantity of Aminogran is increased so the low-phenylalanine protein hydrolysate is decreased and eventually omitted once adequate energy is being taken from solids. Thereafter Aminogran preparations are given mixed as a paste or drink as described for older children. Gradually the Aminogran paste can be spoon-fed and given at feed times with the other foods necessary for the phenylalanine and the energy content of the diet.

For older children Aminogran Food Supplement, in the required calculated quantity for the day, together with the daily dose of Aminogran Mineral Mixture, is mixed into a drink or paste with water and/or an appropriate volume of natural vegetable oil or a 50% vegetable oil emulsion (Prosparol; Duncan, Flockhart & Co. Ltd), sugar and/or natural or synthetic protein-free flavouring, such as milk-shake syrup or concentrate. Sugar or milk-shake flavouring must be added if the oil or emulsion is used, to counteract the ketogenic effect of the fat content. The mixture is divided into three equal portions with one portion being given within 20 minutes of each of the three main meals, which should contain a proportion of the daily phenylalanine allowance. A separate drink should be given if the Aminogran mixture is administered as a paste because of the high solute content of the mixture. Administration with a meal is important as some phenylalanine is necessary to ensure that the amino-acid mixture (dietary nitrogen) is utilised for growth.

From school age the Aminogran mixture may be more practically given as two doses daily with two meals.

The daily requirements of energy, Aminogran Food Supplement and phenylalanine are shown in the table.

1. Approximately 1–1.5 g or as appropriate according to natural protein intake to give 1.5–2.0 g protein plus amino acids per kg per day.

2. Approximately 1 g or as appropriate according to natural protein intake to give 1.5 g protein plus amino acids per kg per day.

The daily dose of Aminogran Food Supplement is calculated on the actual body weight in kilograms. The required quantity can be easily measured with the scoop provided, which, when levelled off with a knife edge, contains 5 g. Aminogran Food Supplement should be prescribed to the nearest half-scoop measurement. Aminogran Food Supplement is phenylalanine free so that it is essential it is not used as the sole source of protein nitrogen but that the diet should contain sources of phenylalanine from natural foods together with low-protein foods and energy foods such as sugar, protein-free starches, fat or oil. Special low-protein foods such as breads and biscuits are also available. As phenylalanine is an essential amino acid it is of particular

importance that the growing child is not exposed to phenylalanine deficiency which can easily arise from an increased requirement in association with accelerated growth rate, inadequate absorption of phenylalanine due to vomiting, refusal of diet or inadequate replacement of phenylalanine, or inaccurate measurement of concentrated phenylalanine sources.

Although the exact threshold levels of maternal blood phenylalanine that can prove injurious to the foetus are not known it is recommended that blood phenylalanine levels of 0.2–0.5 mmols/litre (3–8 mg/100 ml) be maintained throughout pregnancy of women with phenylketonuria. Ideally the blood phenylalanine level should be maintained within the recommended range prior to

Guide to daily requirements in dietary management of classical phenylketonuria

Age (years)	Energy per kg actual body weight kilo Joules (Calories)	Aminogran Food Supplement per kg actual body weight (g)	Initial dose of phenylalanine* per kg actual body weight from other foods (mg)
0–1	420–630 (100–150)	3	50 to 60 and if necessary up to 110
1–2	380–420 (90–100)	2–3	30–40
2–4	330–420 (80–100)	2	25–40
4–6	330–420 (80–100)	2	25
6–8	290–380 (70–90)	2	15–25
8–14	230–310 (55–75)	see footnote 1	As tolerance
Over 14	190 (45)	see footnote 2	As tolerance

* This suggested initial starting dose must subsequently be adjusted according to the results of initially very frequent and then regular tests of blood phenylalanine levels.

1. Approximately 1 to 1.5 g or as appropriate according to natural protein intake to give 1.5 to 2.0 g protein plus amino acids per kg per day.

2. Approximately 1 g or as appropriate according to natural protein intake to give 1.5 g protein plus amino acids per kg per day.

Infections or any other situation causing catabolism increases blood phenylalanine levels. It is recommended that the dietary phenylalanine be continued along with a source of easily digested calories such as sugary drinks if the infection continues for more than two or three days, though the Aminogran Food Supplement can be temporarily omitted.

Because of the preponderance of synthetic foods in the diet adequate vitamin supplementation is essential. Rashes, failure to thrive, and even death can result from a deficiency of phenylalanine or vitamins such as choline chloride, calcium pantothenate, inositol, biotin, α -tocopherol, vitamin B₁₂ and folic acid. A complete vitamin supplement is provided by 3 Ketovite Tablets (Paines & Byrne Ltd) plus 5 ml of Ketovite Liquid each day. For young children Ketovite Tablets should be crushed, suspended in the Ketovite Liquid and given once daily as a medicine.

The aim of dietary management in children with Aminogran is to maintain the blood phenylalanine concentration between 0.2 and 0.5 mmols/litre (3 and 8 mg/100 ml). For this the blood phenylalanine levels should be monitored at regular intervals and the phenylalanine (natural protein) allowance adjusted as necessary.

Women with phenylketonuria in pregnancy: The children of mothers with untreated phenylketonuria have a very high incidence of congenital abnormalities, including mental retardation, intrauterine and postnatal retardation of growth, microcephaly, skeletal, cardiac and ocular manifestations. Patients treated from early life are now reaching reproductive age and it is suggested that all their pregnancies should be planned and dietary restriction together with Aminogran Food Supplement and Mineral Mixture should commence before stopping the contraceptive method and prior to conception. Even then it is impossible to guarantee that the child will be normal at birth.

the onset of pregnancy but when this has not been planned the diet with Aminogran preparations should be instituted as soon as pregnancy is suspected. It should be then continued until the onset of labour. More frequent monitoring of the blood phenylalanine level during pregnancy is mandatory because of the increasing demand for phenylalanine by the growing foetus. This is of particular importance during the third trimester of pregnancy.

Initially a protein plus amino acid intake of 1 g/kg body weight using Aminogran Food Supplement is the suggested dose provided that the total intake of protein is not less than 50 g per day. Phenylalanine from natural foods should be given as indicated by previous tolerance. Initially 15 mg/kg is suggested, adjusted according to tolerance and increasing with foetal growth. The total diet should provide the energy requirement to maintain satisfactory weight gain and any weight loss should be avoided as it causes blood phenylalanine levels to rise.

Contra-indications, warnings, etc

Contra-indications: Aminogran Food Supplement is prepared solely for the dietary management of phenylketonuria and is unsuitable for the dietary management of any other disorder or to form part of the nutrition of normal persons.

Precautions: Aminogran Food Supplement when mixed with Aminogran Mineral Mixture presents a high osmolar load that requires an adequate fluid intake, especially in infants and young children.

Care should be taken to ensure all patients taking the Aminogran diet consume the full calculated diet which must contain adequate energy foods. If the diet is insufficient in energy the blood phenylalanine concentration will show an increase due to catabolism of body protein. The existence of an infection will also cause a rise in blood phenylalanine but under these circumstances appetite should be the guide to nutritional intake.

The priority will be for high-energy protein-free drinks and the phenylalanine allowance, in foods such as milk, is only a secondary consideration. Only if milk is acceptable should the mixture of Aminogran Food Supplement and Aminogran Mineral Mixture be administered. A temporary period without Aminogran, as in any child not eating during an infection, does no harm and blood level control of phenylalanine returns when the infection is over.

Side-effects: No side-effects arise from administration of Aminogran Food Supplement so long as there is correct dietary management to avoid too high or too low a blood level of phenylalanine. The high osmolality may give rise to vomiting and/or diarrhoea but can be overcome by additional fluid. Parental or patient anxiety over the dietary regime and/or diagnosis may cause similar effects so careful frequent supervision and monitoring of the diet is essential.

Overdosage: Not applicable.

Pharmaceutical precautions Store in a cool dry place and ensure that the container lid is always replaced securely.

Legal category P.

Package quantities Aminogran Food Supplement is supplied in containers of 500 g.

Further information A booklet describing the use of Aminogran preparations is available on request. It is advisable that this be consulted before Aminogran Food Supplement is prescribed.

Product licence number 0045/0114.

AMINOGRAN[®] MINERAL MIXTURE

Presentation Aminogran Mineral Mixture contains all the necessary minerals for balanced nutrition in the correct proportions for human needs and is intended for use with Aminogran Food Supplement (see separate Data Sheet for Aminogran Food Supplement). Aminogran Mineral Mixture is packed as 250 g in a yellow polythene bag in a cylindrical plastic container with cardboard carton. The mixture is a mottled white powder. A yellow measuring scoop is provided which contains 2.7 g when levelled with a knife edge. Three scoops provide the usual daily dose of 8 g.

Uses Aminogran Mineral Mixture is indicated in conjunction with Aminogran Food Supplement for the dietary management of phenylketonuria. Aminogran Mineral Mixture is also indicated as an adjuvant in the treatment of the following conditions:

1. Other disorders of amino-acid metabolism such as maple syrup urine disease and homocystinuria.
2. Urea cycle defects. These include carbamyl phosphate synthetase deficiency, ornithine carbamyl transferase deficiency, argininosuccinate synthetase deficiency (citrullinaemia), argininosuccinase deficiency (argininosuccinaciduria), arginase deficiency (hyperargininaemia), hyperlysinaemia and other urea cycle defects as they are recognised.
3. Organicacidurias. These include hypervalinaemia, isovalericaciduria, beta-methylcrotonylglycinuria, alpha-methylacetoaceticaciduria and propionicaciduria.
4. In conjunction with artificial diets used in the treatment of food intolerance with malabsorption.

5. In any diet in infants and children where there is severe restriction of natural food, such as in some ketogenic diets for the treatment of epilepsy.

Content per 100 g and per 8 g dose

	per 100 g		per 8 g dose	
Potassium	8.3 g	0.21 mol	0.66 g	17 mmol
Calcium	8.1 g	0.20 mol	0.65 g	16 mmol
Phosphorus	6.0 g	0.19 mol	0.48 g	15 mmol
Sodium	4.0 g	0.17 mol	0.32 g	14 mmol
Magnesium	0.97 g	40 mmol	77 mg	3.2 mmol
Iron	63 mg	1 mmol	5 mg	90 micromol
Zinc	48 mg	0.7 mmol	4 mg	59 micromol
Copper	13 mg	0.2 mmol	1 mg	16 micromol
Manganese	4 mg	81 micromol	0.4 mg	6 micromol
Iodine				
Aluminium				
Cobalt				
Molybdenum				
Trace quantities				

Dosage and administration Used for the dietary management of phenylketonuria, with Aminogran Food Supplement, it is recommended that the total daily intake of Aminogran Mineral Mixture is 8 g per day, provided that the patient's body weight is not less than 5.5 kg. For infants under 5.5 kg body weight the dosage is calculated on the basis of 1.5 g/kg/day. Solutions with a high osmolality may cause vomiting, abdominal pain and diarrhoea in young infants so that it is advised that each gram of Aminogran Mineral Mixture should be diluted for infants with at least 100 ml of fluid. The usual method of administration is to prepare a drink or paste of Aminogran Food Supplement, in the required daily quantity (see separate Data Sheet for this product), together with three level, unpacked scoops (8 g) of Aminogran Mineral Mixture. The drink or paste may be prepared with water and/or a vegetable oil or emulsion (Prosparol; Duncan, Flockhart & Co. Ltd) sugar and/or protein-free flavouring such as fruit, milk-shake, syrup or concentrate. If the oil is included then sugar should be added. The drink or paste is divided into three equal portions and one portion taken with each of the three main meals of the day like a dose of medicine and washed down with water or fruit juice. For older children the preparation may be divided into two portions with each portion taken with a convenient main meal. Some food containing natural protein must be consumed at the time of administration to supply the phenylalanine necessary for utilisation of the amino acids for growth. Aminogran Mineral Mixture may be similarly used in the other conditions for which it is indicated.

Contra-indications, warnings, etc

Contra-indications: Aminogran Mineral Mixture is unsuitable for use where trace element supplementation only is required. If used for infants of less than 5.5 kg body weight the total daily dose should not exceed 1.5 g per kg body weight.

Precautions: When used in infants under the age of six months each 1 g of Aminogran Mineral Mixture must be diluted with at least 100 ml of fluid. For older children a drink to follow is satisfactory.

Side-effects: Mineral solutions with high osmolality may cause vomiting, abdominal pain and diarrhoea. This may be avoided by dilution as advised under 'Precautions'.

Overdosage: If Aminogran Mineral Mixture is inadvertently given to infants in excess of the recommended

dose of 1.5 g/kg/day or inadequately diluted to at least 1 g per 100 ml, symptoms of hyperosmolarity may occur and the serum electrolytes should be checked. Treatment is administration of fluids by the oral or, if necessary, parenteral routes.

Pharmaceutical precautions Store below 25°C in a dry place and ensure that the container lid is always replaced securely.

Legal category P.

Package quantities Aminogran Mineral Mixture is supplied in containers of 250 g.

Further information It is essential that the Data Sheet for Aminogran Food Supplement is consulted for a full understanding of the use of Aminogran preparations in the dietary management of phenylketonuria. A booklet describing the use of Aminogran preparations in phenylketonuria is available on request and it is advisable that it should be read before the products are prescribed.

Product licence number 0045/0115.

BECONASE* NASAL SPRAY

Presentation Beconase Nasal Spray is a metered-dose aerosol which delivers 50 mcg Beclomethasone Dipropionate BP per actuation into a specially designed nasal applicator.

Uses Beconase is indicated for the prophylaxis and treatment of perennial and seasonal allergic rhinitis, including hay fever and vasomotor rhinitis. Beclomethasone Dipropionate BP has a potent anti-inflammatory effect within the respiratory tract at doses which are not systemically active.

Dosage and administration Beconase is for administration by the intranasal route only. The recommended dosage is two applications into each nostril twice daily (400 mcg/day).

For some patients, a dosage regimen of a single application into each nostril three or four times daily may be preferred. Total daily administration should not normally exceed 8 puffs.

For full therapeutic benefit regular usage is essential. The co-operation of the patient should be sought to comply with the regular dosage schedule and it should be explained that maximum relief may not be obtained with the first few applications. Not for use in children under six years of age.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications to the use of Beconase.

Precautions: Infections of the nasal passages and paranasal sinuses should be appropriately treated but do not constitute a specific contra-indication to treatment with Beconase.

Care must be taken while transferring patients from systemic steroid treatment to Beconase if there is any reason to suppose that their adrenal function is impaired.

Although Beconase Nasal Spray will control seasonal allergic rhinitis in most cases, an abnormally heavy challenge of summer allergens may in certain instances necessitate appropriate additional therapy.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: No major side-effects attributable to Beconase have been reported, but occasionally sneezing attacks have followed immediately after the use of the aerosol.

Overdosage: The only harmful effect that follows inhalation of large amounts of the drug over a short time period is suppression of hypothalamic-pituitary-adrenal (HPA) function. No special emergency action need be taken. Treatment with Beconase Nasal Spray should be continued at the recommended dose. HPA function recovers in a day or two.

Pharmaceutical precautions Beconase should be stored at a temperature below 30°C. Exposure to direct sunlight or heat should be avoided. The canister should not be punctured, broken or burnt even if it is apparently empty.

Legal category POM.

Package quantities Beconase Nasal Spray is a metered-dose aerosol with a specially designed nasal applicator. Each canister provides 200 sprays.

Further information When Beconase is administered as two applications into each nostril the first puff should be directed at the upper and the second at the lower part of the nasal cavity.

Product licence number 0045/0093.

BECOTIDE* INHALER

Presentation Becotide Inhaler is a metered-dose aerosol which delivers 50 mcg Beclomethasone Dipropionate BP per actuation into the mouthpiece of a specially designed actuator.

Uses Beclomethasone Dipropionate BP given by inhalation has a potent glucocorticoid anti-inflammatory action within the lungs but does not cause adverse systemic glucocorticoid effects at therapeutic doses. Becotide Inhaler therefore is indicated for a wide range of patients with bronchial asthma.

These patients include: those whose asthma is becoming worse and the relief provided by bronchodilators is less effective; those who are inadequately controlled by sodium cromoglycate in addition to bronchodilators; those with severe asthma who are dependent on systemic corticosteroids, or adrenocorticotrophic hormone (ACTH) or its synthetic equivalent.

Becotide Inhaler is particularly important for managing severe asthma in children because good control can be achieved without retardation of growth.

Dosage and administration *Adults:* 2 inhalations (100 mcg) three or four times a day is the usual maintenance dose. Alternatively, the total daily dose may be administered as two divided doses. In severe cases dosage may be started at 600–800 mcg per day and subsequently reduced when the patient begins to respond.

Children: 1 or 2 inhalations (50–100 mcg) should be given two, three or four times daily, according to the response.

Contra-indications, warnings, etc

Contra-indications: No specific contra-indications to Becotide Inhaler are known, but special care is necessary in patients with active or quiescent pulmonary tuberculosis.

Precautions: Patients should be instructed on the proper use of the inhaler to ensure that the drug reaches the target areas within the lungs. They should also be made aware that Becotide Inhaler has to be used regularly for optimum benefit.

The maximum daily intake of Becotide Inhaler should not exceed 20 inhalations (1 mg); significant reduction of plasma cortisol levels has been reported in patients who received twice this amount.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Patients inadequately controlled by bronchodilator therapy: The use of Becotide Inhaler in patients who have never taken steroids or taken only occasional courses of steroids is straightforward. An improvement in respiratory function is obvious within a week. The few patients who do not respond during this period usually have excessive mucus in their bronchi so that the drug is unable to penetrate to its site of action. In such cases a short course of systemic steroid in relatively high dosage should be given to control secretion of mucus and other inflammatory changes in the lungs. Continuation of treatment with Becotide Inhaler usually maintains the improvement achieved, the oral steroid being gradually withdrawn. Exacerbation of asthma caused by infection is usually controlled by appropriate antibiotic treatment, by increasing the dose of Becotide Inhaler and if necessary by giving systemic steroid.

Steroid-dependent patients: The transfer of steroid-dependent patients to Becotide Inhaler and their subsequent management needs special care mainly because recovery from impaired adrenocortical function, caused by prolonged systemic steroid therapy, is slow. The patient should be in a reasonably stable state before being given Becotide Inhaler in addition to his usual maintenance dose of systemic steroid. After about a week, gradual withdrawal of the systemic steroid is started by reducing the daily dose by 1 mg prednisolone, or its equivalent of other corticosteroid, at not less than weekly intervals. Patients treated with systemic steroids for long periods of time or who have received high doses may have adrenocortical suppression. With these patients adrenocortical function should be monitored regularly and their dose of systemic steroid reduced cautiously. Some patients feel unwell during the withdrawal phase despite maintenance or even improvement of respiratory function. They should be encouraged to persevere with the inhaler and withdrawal of systemic steroids continued, unless there are objective signs of adrenal insufficiency. Most patients can be successfully transferred to Becotide Inhaler with maintenance of good respiratory function, but special care is necessary for the first months after the transfer until the pituitary-adrenal system has sufficiently recovered to enable the patient to cope with emergencies such as trauma, surgery or infections. Transferred patients whose adrenocortical function is impaired should carry a warning card indicating that they need supplementary systemic steroid during periods of stress. They should also be given a supply of oral steroid to use in emergency, for example when the asthma worsens as a result of a chest infection. The dose of Becotide Inhaler should be increased at this time and then reduced to the maintenance level after the systemic steroid has been discontinued.

Replacement of systemic steroid treatment with Becotide Inhaler sometimes unmasks allergies such as allergic rhinitis or eczema previously controlled by the

systemic drug. These allergies should be symptomatically treated with antihistamine and/or topical preparations.

Side-effects: No major side-effects attributable to the use of recommended doses of Becotide Inhaler have been reported. Candidiasis of the mouth and throat (thrush) occurs in some patients; patients with high blood levels of Candida precipitins, indicating a previous infection, are more likely to develop this complication. The incidence of candidiasis is increased with doses greater than 400 mcg beclomethasone dipropionate per day. The condition usually responds to topical antifungal therapy without discontinuing treatment with Becotide Inhaler.

Overdosage: The acute toxicity of beclomethasone dipropionate is low. The only harmful effect that follows inhalation of large amounts of the drug over a short time period is suppression of hypothalamic-pituitary-adrenal (HPA) function. No special emergency action need be taken. Treatment with Becotide Inhaler should be continued at the recommended dose to control the asthma; HPA function recovers in a day or two.

Reduction of plasma cortisol levels has been reported in patients who received twice the recommended maximum dose of Becotide Inhaler. In the unlikely event of grossly excessive intake of beclomethasone dipropionate for weeks or months on end a degree of adrenocortical atrophy could occur in addition to suppression of HPA function. The patient should be treated as steroid-dependent and transferred to a suitable maintenance dose of a systemic steroid such as prednisolone. Once the patient's condition is stabilised he should be transferred to Becotide Inhaler by the method recommended in this Data Sheet.

Pharmaceutical precautions *Storage:* Becotide Inhaler should be stored at a temperature below 30°C. Direct sunlight and heat should be avoided.

The canister should not be punctured, broken or burnt even if it is apparently empty.

Legal category POM.

Package quantities Becotide Inhaler is a metered-dose aerosol with a specially designed actuator. Each canister provides 200 inhalations.

Further information Nil.

Product licence number 0045/0089.

BECOTIDE* ROTACAPS*

Presentation Becotide Rotacaps, an alternative inhalation form of beclomethasone dipropionate to Becotide Inhaler, are especially valuable for treating patients who are unable to use pressurised inhalers effectively or who might use them incorrectly.

Becotide Rotacaps contain a mixture of microfine beclomethasone dipropionate and larger particle lactose in buff or chocolate-brown/colourless hard gelatine cartridges. Each Rotacap contains 100 mcg (buff) or 200 mcg (chocolate-brown) of beclomethasone dipropionate and is marked Becotide 100 or Becotide 200. The contents of a Rotacap are inhaled using a specially developed device called a Rotahaler*, which separates the cartridge into halves that rotate and release the drug when the patient inhales. This breath actuation is very sensitive and so the drug is fully available even at the lowest inspiratory flow rates. The Rotahaler is therefore a more reliable drug delivery system for many patients

but a rather larger unit dose relative to Becotide Inhaler is necessary for the same therapeutic effect.

Uses Beclomethasone Dipropionate BP given by inhalation has a potent glucocorticoid anti-inflammatory action within the lungs but does not cause adverse systemic glucocorticoid effects at therapeutic doses. Becotide Rotacaps therefore are indicated for a wide range of patients with bronchial asthma. These patients include: those whose asthma is becoming worse and the relief provided by bronchodilators is less effective; those who are inadequately controlled by sodium cromoglycate in addition to bronchodilators; those with severe asthma who are dependent on systemic corticosteroids, or adrenocorticotrophic hormone (ACTH) or its synthetic equivalent.

Becotide Rotacaps are particularly important for managing severe asthma in children because good control can be achieved without retardation of growth.

Dosage and administration Becotide Rotacaps are for inhalation use only, using a Becotide Rotahaler. For optimum results Becotide Rotacaps should be used regularly.

Adults: One 200 mcg Rotacap three or four times a day is the usual maintenance dose. Alternatively, the total daily dose may be administered as two divided doses.

Children: One 100 mcg Rotacap two, three or four times a day, according to the response.

Contra-indications, warnings, etc

Contra-indications: No specific contra-indications to Becotide Rotacaps are known, but special care is necessary in patients with active or quiescent pulmonary tuberculosis.

Precautions: Patients should be instructed in the proper use of the Rotahaler to ensure that the drug reaches the target areas within the lungs. They should also be made aware that Becotide Rotacaps have to be used regularly for optimum benefit.

The maximum daily intake of beclomethasone dipropionate should not exceed 1 mg; significant reduction of plasma cortisol levels has been reported in patients who received twice this amount.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Patients inadequately controlled by bronchodilator therapy: The use of Becotide Rotacaps in patients who have never taken steroids or taken only occasional courses of steroids is straightforward. An improvement in respiratory function is obvious within a week. The few patients who do not respond during this period usually have excessive mucus in their bronchi so that the drug is unable to penetrate to its site of action. In such cases a short course of systemic steroid in relatively high dosage should be given to control secretion of mucus and other inflammatory changes in the lungs. Continuation of treatment with Becotide Rotacaps usually maintains the improvement achieved, the oral steroid being gradually withdrawn. Exacerbation of asthma caused by infection is usually controlled by appropriate antibiotic treatment, by increasing the dose of Becotide Rotacaps and if necessary by giving systemic steroid.

Steroid-dependent patients: The transfer of steroid-dependent patients to Becotide Rotacaps and their subsequent management needs special care mainly because recovery from impaired adrenocortical function, caused by prolonged systemic steroid therapy, is slow. The patient should be in a reasonably stable state before

being given Becotide Rotacaps in addition to his usual maintenance dose of systemic steroid. After about a week, gradual withdrawal of the systemic steroid is started by reducing the daily dose by 1 mg prednisolone, or its equivalent of other corticosteroid, at not less than weekly intervals. Patients treated with systemic steroids for long periods of time or who have received high doses may have adrenocortical suppression. With these patients adrenocortical function should be monitored regularly and their dose of systemic steroid reduced cautiously. Some patients feel unwell during the withdrawal phase despite maintenance or even improvement of respiratory function. They should be encouraged to persevere with the Rotacaps and withdrawal of systemic steroid continued unless there are objective signs of adrenal insufficiency. Most patients can be successfully transferred to Becotide Rotacaps with maintenance of good respiratory function, but special care is necessary for the first months after the transfer until the pituitary-adrenal system has sufficiently recovered to enable the patient to cope with emergencies such as trauma, surgery or infections. Transferred patients whose adrenocortical function is impaired should carry a warning card indicating that they need supplementary systemic steroid during periods of stress. They should also be given a supply of oral steroid to use in emergency, for example when the asthma worsens as a result of a chest infection. The dose of Becotide Rotacaps should be increased at this time and then reduced to the maintenance level after the systemic steroid has been discontinued.

Replacement of systemic steroid treatment with Becotide Rotacaps sometimes unmasks allergies such as allergic rhinitis or eczema previously controlled by the systemic drug. These allergies should be symptomatically treated with antihistamine and/or topical preparations.

Side-effects: No major side-effects attributable to the use of recommended doses of Becotide Rotacaps have been reported. Candidiasis of the mouth and throat (thrush) occurs in some patients; patients with high blood levels of Candida precipitins, indicating a previous infection, are more likely to develop this complication. The condition usually responds to topical anti-fungal therapy, without discontinuing treatment with Becotide Rotacaps.

Overdosage: The acute toxicity of beclomethasone dipropionate is low. The only harmful effect that follows inhalation of large amounts of the drug over a short time period is suppression of hypothalamic-pituitary-adrenal (HPA) function. No special emergency action need be taken. Treatment with Becotide Rotacaps should be continued at the recommended dose to control the asthma; HPA function recovers in a day or two.

Reduction of plasma cortisol levels has been reported in patients who received twice the recommended maximum dose of beclomethasone dipropionate. In the unlikely event of grossly excessive intake of beclomethasone dipropionate for weeks or months on end a degree of adrenocortical atrophy could occur in addition to suppression of HPA function. The patient should be treated as steroid-dependent and transferred to a suitable maintenance dose of a systemic steroid such as prednisolone. Once the patient's condition is stabilised he should be transferred to Becotide Rotacaps by the method recommended in this Data Sheet.

Pharmaceutical precautions To keep the Rotacaps in good condition it is important that they are stored in a dry place where they will not be exposed to extremes

of temperature. A convenient supply may be carried in the special container for the Rotahaler. The Rotacaps should only be inserted in the Rotahaler immediately prior to use. Failure to observe this instruction may affect the operation of the Rotahaler.

Legal category POM.

Package quantities Becotide Rotacaps 100 mcg and 200 mcg are supplied in containers of 100.

Further information Nil.

Becotide Rotacaps 200 micrograms 0045/0120

EUDEMINE* TABLETS 50 mg

EUDEMINE* INJECTION

Presentation Eudemine Tablets 50 mg are white, sugar-coated tablets each containing Diazoxide BP 50 mg. Identification code AH/8D.

Eudemine Injection. Ampoules of 20 ml containing Diazoxide BP 300 mg in an aqueous, colourless solution with sodium hydroxide at pH 11.6.

Uses Diazoxide is a benzothiadiazine analogue which has two main therapeutic actions. Clinically it is used in the treatment of intractable hypoglycaemia, and for the treatment of severe hypertension associated with renal disease and for patients resistant to conventional hypotensive agents. Diazoxide also causes salt and water retention.

Hypoglycaemia: Eudemine administered orally is indicated for the treatment of intractable hypoglycaemia with severe symptoms from a variety of cases including: idiopathic hypoglycaemia of infancy, leucine-sensitive or unclassified; functional islet-cell tumours both malignant and benign if inoperable, extra-pancreatic neoplasms producing hypoglycaemia; glycogen storage disease; hypoglycaemia of unknown origin.

Hypertensive emergencies: Eudemine Injection is used particularly for the emergency treatment of acute hypertensive crises, especially those occurring in association with acute hypertensive encephalopathy, congestive heart failure, acute glomerular nephritis, eclampsia or pre-eclampsia.

Severe hypertension: It is also indicated for the control of severe hypertension associated with renal disease.

In hypertensive patients requiring such diagnostic procedures as renal biopsy, arteriography or cardiac catheterisation, Eudemine Injection may be given to facilitate the procedure and reduce the danger of haemorrhage due to hypertension. Eudemine injection is also indicated in patients who have failed to respond to other hypotensive agents.

Eudemine Tablets may be used to treat patients with severe hypertension associated with renal disease or where the conventional hypotensive agents have failed. It is also possible that Eudemine Tablets may be used as maintenance therapy in patients who have had their hypertension controlled initially with Eudemine Injection.

Dosage and administration *Hypoglycaemia:* In hypoglycaemia the dosage schedule of Eudemine Tablets is determined according to the clinical needs and the response of the individual patient. For both adults and children a starting oral dose of 5 mg/kg body weight divided into 2 or 3 equal doses per 24 hours will establish the patient's response and thereafter the dose can be

increased until the symptoms and blood glucose level respond satisfactorily. Regular determinations of the blood glucose in the initial days of treatment are essential. In children with leucine-sensitive hypoglycaemia, a dosage range of 15–20 mg/kg/day is suggested.

In adults with benign or malignant islet-cell tumours producing large quantities of insulin, high dosages of up to 1,000 mg per day have been used.

Hypertensive emergencies and severe hypertension: In the treatment of hypertension, Eudemine Injection is administered by the intravenous route only and it should never be given intramuscularly or subcutaneously.

Adults: A full dose of 300 mg in 20 ml will be required by most patients. However, an adequate fall in blood pressure in some patients may be obtained with as little as 150 mg. Patients must be recumbent during the injection which must be rapid and not exceed 30 seconds.

Children: On the rare occasions that Eudemine Injection is indicated for hypertension in children the dosage should be based on a level of 5 mg per kg body weight by injection.

A response occurs within five minutes and usually persists for at least four hours. One injection is usually effective, but further injections may be required, particularly in hypertensive crises or in accelerating disease refractory to other hypotensive agents. Up to four ampoules of 300 mg may be given in 24 hours. An initial dose of 600 mg is recommended only in life-threatening situations. Once the blood pressure is controlled by Eudemine Injection, treatment with anti-hypertensive agents designed for maintenance therapy can be initiated. It appears that if hypertensive patients treated with Eudemine Injection are allowed an unrestricted sodium intake then the subsequent response to oral hypotensive agents will be improved.

When Eudemine Tablets are used in the treatment of hypertension the dosage ranges from 400 mg to 1,000 mg daily, given in 2 or 3 divided doses. Apart from obtaining control over hypertension, dosage adjustment may also be occasioned by the development of side-effects.

Contra-indications, warnings, etc

Contra-indications: In the treatment of hypoglycaemia, Eudemine is contra-indicated in all cases which are amenable to surgery or other specific therapy.

There are no absolute contra-indications to Eudemine for the relief of hypertension but it should be used with discretion. Agents which can be given by infusion, such as hydralazine or labetalol, should have been shown to be ineffective before a bolus injection of diazoxide is given.

Precautions: Each of the two main therapeutic actions of Eudemine tend to be unwanted effects when the product is used for the alternative main indication. Thus in the treatment of hypoglycaemia it is necessary that the blood pressure be monitored regularly, whilst in the treatment of hypertension long-term therapy with Eudemine necessitates regular monitoring of the blood glucose levels.

In either indication, retention of sodium and water is likely to necessitate therapy with an oral diuretic such as frusemide or ethacrynic acid. The dosage of either of the diuretics mentioned may be up to 1 g daily. It must be appreciated that if diuretics are employed then both the hypotensive and the hyperglycaemic activities of diazoxide will be potentiated and it is likely that the dosage

of diazoxide will require adjustment downwards. In patients with severe renal failure it is desirable to maintain, with diuretic therapy, urinary volumes in excess of 1 litre daily. Hypokalaemia should be avoided by adequate potassium replacement.

In the long-term treatment of hypertension with oral diazoxide it is advisable to employ four-hourly diabetic urine testing in the initial stages. Explosive forms of hyperglycaemia will occur early, if at all, so that with maintenance therapy diabetic urine testing will only be required twice daily. Control of hyperglycaemia is usually effected with tolbutamide, of which the dosage should be regulated by the results of regular monitoring of the blood sugar.

Whenever Eudemine is given over a prolonged period regular haematological examinations are indicated to exclude changes in white blood cell and platelet counts. Also in children, there should be regular assessment of growth, bone and psychological maturation.

Eudemine Tablets are only to be used in pregnant women when the indicated condition is deemed to put the mother's life at risk.

With Eudemine Injection the high alkalinity of the solution necessitates that great care is taken to ensure that the injection is given directly into a vein without leakage into surrounding tissues.

The very rapid, almost complete protein binding of diazoxide requires cautious dosage to be used in patients whose plasma proteins may be lower than normal.

Side-effects: In the treatment of hypertension the hyperglycaemia induced by diazoxide is generally inevitable. Each injection of diazoxide usually means a transient rise in blood sugar of about 10%. Fortunately the hyperglycaemia in hypertensive patients can be readily controlled with tolbutamide, or exceptionally with insulin. A hypotensive effect in normotensive patients is of minor importance and rarely requires any specific therapy. An oral diuretic may be indicated to control sodium and water retention.

With Eudemine Injection reflex tachycardia is not uncommon in the first few minutes after injection and is more frequent in digitalised patients. Orthostatic hypotension is unlikely but it may occur in those recently treated with adrenergic blocking agents. When it is used during labour for the treatment of toxæmia, the smooth muscle relaxant effect can cause delay in the second stage. This should be counteracted with oxytocic agents.

With oral therapy nausea is common in the first two or three weeks and may require relief with an anti-nauseant. Prolonged therapy has given rise to reports of hypertrichosis lanuginosa, anorexia and hyperuricaemia. In the treatment of hypertension with oral Eudemine a recent report has confirmed the extrapyramidal side-effects which have been reported with oral diazoxide in the treatment of hypoglycaemia. In oral hypotensive therapy, it was found that extra-pyramidal effects, such as Parkinsonian tremor, cogwheel rigidity and oculogyric crises, could be easily suppressed by intravenous injection of an anti-Parkinsonian drug such as procyclidine and that they could be prevented by maintenance therapy with such a drug given orally.

Prolonged oral therapy of Eudemine during pregnancy has been reported to cause alopecia in the newborn.

Other adverse effects of Eudemine which have been reported are hyperosmolar non-ketotic coma, cardiomegaly, leucopenia and thrombocytopenia.

Drugs potentiated by diazoxide therapy include: oral diuretics, antihypertensive agents and anticoagulants.

Overdosage: Excessive dosage of Eudemine can result in hyperglycaemia which will respond to insulin; or to hypotension which will necessitate maintenance of blood volume with intravenous fluids.

Pharmaceutical precautions No special storage conditions are needed for Eudemine Tablets.

It is particularly important that Eudemine Injection is protected from light.

Eudemine Injection should never be mixed with other drugs and it should not be diluted.

Legal category POM.

Package quantities Eudemine Tablets 50 mg are packed in containers of 100.

Eudemine Injection is in ampoules individually boxed in packs of five.

Further information Nil.

Eudemine Tablets 50 mg 0045/5081

Eudemine Injection 0045/0084

FENTAZIN* TABLETS FENTAZIN* INJECTION FENTAZIN* CONCENTRATE

Presentation Fentazin Tablets 2 mg each contain Perphenazine BP 2 mg. Identification code is AH/1C.

Fentazin Tablets 4 mg each contain Perphenazine BP 4 mg. Identification code is AH/2C.

Fentazin Tablets 8 mg each contain Perphenazine BP 8 mg. Identification code is AH/4C.

All are white, sugar-coated tablets.

Fentazin Injection contains 5 mg Perphenazine BP in each ampoule of 1 ml. It is colourless.

Fentazin Concentrate contains 8 mg Perphenazine BP in 4 ml. Available to hospitals only.

Uses Fentazin is a potent tranquilliser and anti-emetic of the phenothiazine group. It is indicated in the following: severe anxiety and tension states, particularly where agitation is present; anxiety associated with psychosomatic disorders; severe anxiety associated with obsessive and compulsive disorders; psychotic states characterised by CNS hyperactivity, including schizophrenia of various types and senile psychoses; control of behaviour disorders; nausea and vomiting; adjunctive therapy to analgesics in the management of severe pain, e.g. terminal carcinoma.

Fentazin Injection is indicated in cases where rapid control of symptoms is essential or when oral administration is impracticable.

Fentazin Injection can also be used as pre-medication and for the control of post-operative vomiting.

It may be of value in the control of intractable hiccough.

Dosage and administration Fentazin Tablets are administered orally in a usual dosage of 4 mg perphenazine three times daily. This may be adjusted upwards or downwards according to response, but the total daily dosage should not exceed 24 mg.

Fentazin Injection is administered intramuscularly. The usual initial dose is 5–10 mg, which may be followed by further 5 mg doses at six-hourly intervals.

Children: Fentazin should not be given to children under the age of 14 years.

Contra-indications, warnings, etc

Contra-indications: Fentazin should not be administered to patients with leucopenia or in association with drugs liable to cause bone-marrow depression.

Precautions: Fentazin should be used with caution in patients with congestive heart failure or coronary artery disease. Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: Extrapyramidal symptoms such as dystonia, torsion spasm and pseudo-Parkinsonism may occur. These reactions can be controlled by withdrawal of the drug or reduction of the dosage. Concurrent administration of an anti-Parkinson agent may be used to advantage. Persistent oral dyskinesia has been reported occasionally, particularly in elderly female patients, after long-term treatment with potent phenothiazine drugs including perphenazine.

Overdosage: With oral preparations of Fentazin gastric lavage is recommended. Emetics are likely to be of little value because of the potent anti-emetic activity of the drug. Hypotension is not usually a problem, especially if the patient is passing urine satisfactorily. Severe hypotension may require fluid infusion therapy. Central nervous system depression is best treated conservatively, anaesthetics should not be used. Rewarming measures should not be employed unless the body temperature falls below 30°C. Convulsions may be controlled with standard methods, but the use of barbiturates should be avoided.

Pharmaceutical precautions *Storage:* Fentazin liquid preparations, including Fentazin Injection, should be protected from light.

Dilution: Fentazin Injection should not be mixed with other agents as this may affect the stability of the solution.

Fentazin Concentrate is supplied to hospitals only and must be diluted to the required concentration with unpreserved Syrup BP.

Legal category POM.

Package quantities Fentazin Tablets 2 mg, 4 mg and 8 mg are issued in cartons each containing 100 tablets in 10 foil strips of 10 (5 × 2) tablets.

Fentazin Concentrate is available in bottles of 1 litre to hospitals only, for dilution.

Fentazin injection is available in boxes of 5 and 100 ampoules of 1 ml each containing 5 mg.

Further information Nil.**Product licence numbers**

GUANIMYCIN* SUSPENSION FORTE

Presentation Each bottle of Guanimycin Suspension Forte contains:

Dihydrostreptomycin Sulphate BP 1958	2.5 g
(equivalent to 1.975 g of base)	
Sulphaguanidine BPC	19.85 g
Light Kaolin BP	42.5 g

Guanimycin Suspension Forte is issued in the form of a pleasantly flavoured, orange-coloured suspension ready for immediate use. Each 15 ml dose contains:

Dihydrostreptomycin Sulphate BP 1958	0.25 g
(equivalent to 0.1975 g of base)	
Sulphaguanidine BPC	1.985 g
Light Kaolin BP	4.25 g

Uses The treatment of acute gastro-enteritis and acute diarrhoeal illnesses of bacterial origin including salmonella infections and Sonne dysentery.

Dosage and administration Administration is oral and should start as early as possible. Concomitant with Guanimycin Suspension Forte therapy, the patient, especially the dehydrated patient, must maintain an adequate fluid intake.

Adults: One 15 ml dose four times daily at approximately four-hour intervals, before rather than after food.

Children and infants: The dosage should be based on the patient's age, weight and the severity of the disease. For the average child dosage may be prescribed according to age – the following scale being adequate for all but the more severe infections:

1–4 years: 5 ml every four hours.

5–9 years: 5–10 ml four-hourly.

10–15 years: 10 ml every four hours.

Contra-indications, warnings, etc

Contra-indications: Patients known to be hypersensitive to sulphonamides or derivatives of streptomycin.

Precautions: In infants and children the necessity for maintaining the fluid volume is of paramount importance.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: A single case of hypersensitivity to Guanimycin Suspension Forte has been reported. Apart from this no other side effects are known to have occurred.

Overdosage: Dihydrostreptomycin is very poorly absorbed after oral administration and light kaolin is not absorbed. Sulphaguanidine may be absorbed to a slight extent so that systemic effects, including crystalluria, are possible.

Treatment would consist of the immediate withdrawal of the mixture; the administration of alkalis such as sodium bicarbonate and the maintenance of fluid intake, if necessary by the parenteral route.

Pharmaceutical precautions *Storage:* Store in a cool place.

Dilution: No attempt to dilute Guanimycin Suspension Forte should be made.

Legal category POM.

Package quantities Guanimycin Suspension Forte is supplied in bottles of 150 ml.

Further information The combination of sulphaguanidine and dihydrostreptomycin reduces the likelihood of the emergence of strains of bacteria resistant to dihydrostreptomycin.

Product licence number 0045/5059.

ISOGEL*

Presentation Isogel is a preparation of Ispaghula Husk BP, which consists of the epidermis and collapsed

adjacent layers removed from the dried ripe seeds of *Plantago ovata* Forssk.

Isogel is supplied as small, reddish-pink granules in containers of 200 g.

Uses Isogel is not absorbed from the gastrointestinal tract, but it adsorbs water to form a mucilaginous mass. This results in a purely mechanical stimulus to mass peristalsis without any purgative effect. It is for this reason that Isogel is not only an effective remedy for constipation but is also of value in the treatment of diarrhoea, the irritable bowel syndrome and the management of patients with a colostomy. Isogel is indicated in habitual constipation, including cases due to spastic colon, dietary insufficiencies and in patients with haemorrhoids or diabetes. It can be used to normalise the bowel movement in patients with mucous or ulcerative colitis.

Isogel is a help to patients with colostomy as the formation of a well-formed, easily passed stool assists in the maintenance of cleanliness and the establishment of control.

Dosage and administration The required quantity of Isogel should be stirred briskly into half a glass of water and swallowed at once. An aerated water is frequently preferred and may be easier to swallow.

Adults: 2 teaspoonfuls once or twice daily, preferably at mealtimes.

Children: 1 teaspoonful once or twice daily, preferably at mealtimes.

The above dosage is only a general guide and it should be adjusted to suit the needs of each individual patient.

In diarrhoea the dose, usually 1 teaspoonful, is taken three times daily until symptoms abate.

Contra-indications, warnings, etc

Contra-indications: Nil.

Precautions: A few cases of inhalation of the mucilaginous mass which forms on allowing an Isogel/water mixture to stand have been reported. In consequence, it is important that Isogel should be swallowed immediately after mixing, and elderly or debilitated patients should be supervised whilst taking it.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: Nil.

Overdosage: As Isogel is not absorbed and it has no purgative action the problem of overdosage does not arise.

Pharmaceutical precautions *Storage:* Store in a cool dry place.

Legal category GSL.

Package quantities Isogel is supplied in containers of 200 g.

Further information Nil.

Product licence number 0045/5028.

PIRITON* TABLETS PIRITON* SPANDETS* PIRITON* DUOLETS* PIRITON* SYRUP PIRITON* INJECTION

Presentation Piriton is a potent antihistamine (Chlor-

pheniramine Maleate BP) presented as tablets, sustained-action tablets, syrup and injection.

Piriton Tablets: Round, biconvex, yellow tablets each containing Chlorpheniramine Maleate BP 4 mg. Identification engraved Piriton AH.

Piriton Spandets*: Yellow and white, round, layered tablets each containing Chlorpheniramine Maleate BP 12 mg. After swallowing 4 mg Chlorpheniramine Maleate BP is released immediately from the yellow layer and then a further 8 mg chlorpheniramine maleate is gradually released from the special porous matrix comprising the white layer. Identification engraved Piriton AH Spandet.

Piriton Duolets*: Round, yellow, sugar-coated tablets each containing Chlorpheniramine Maleate BP 8 mg. The outer layer contains 4 mg for immediate release and the inner core contains 4 mg for delayed release. Printed in black on each tablet PIRITON AH DUOLET.

Piriton Syrup: Each 10 ml of Piriton Syrup contains Chlorpheniramine Maleate BP 4 mg. It is colourless.

Piriton Injection: Each 1 ml of Piriton Injection contains Chlorpheniramine Maleate BP 10 mg. It is colourless.

Uses The oral preparations of Piriton are indicated for symptomatic control of all allergic conditions responsive to antihistamines, including hay fever, vasomotor rhinitis, urticaria, angioneurotic oedema, food allergy, drug and serum reactions, pruritus ani et vulvae, insect bites.

Piriton Injection is indicated for acute urticaria, insect bites and stings, angioneurotic oedema, drug and serum reactions, desensitisation reactions, hay fever, vasomotor rhinitis, severe pruritus of non-specific origin.

Dosage and administration *Piriton Tablets:*

Adults: 1 tablet three or four times a day.

Children (aged 6–12 years): $\frac{1}{2}$ –1 tablet three or four times a day.

Piriton Spandets: **Adults:** 1 Spandet every 8–12 hours.

Children (over 12 years of age): 1 Spandet daily.

Piriton Spandets must be swallowed whole and not chewed.

Piriton Duolets: **Adults:** 1 Duolet should be taken every 8–10 hours.

Children (over 12 years of age): 1 Duolet daily.

Piriton Syrup: **Adults:** Two 5 ml spoonfuls three or four times a day.

Children (up to 1 year): $\frac{1}{2}$ spoonful (2.5 ml) twice daily.

Children (1–5 years): $\frac{1}{2}$ –1 spoonful (2.5–5 ml) three times daily.

When Piriton Syrup is dispensed to meet prescriptions involving doses of 2.5 ml it should be diluted with an equal quantity of unpreserved Syrup BP. The resultant mixture should be used within 14 days.

Piriton Injection: The injection may be subcutaneous, intramuscular or intravenous. The latter is recommended when a rapid effect is desired as in anaphylactic reactions. For the intravenous route Piriton should be diluted in the syringe with 5–10 ml of blood and then injected slowly over a period of one minute. Any drowsiness, giddiness or hypotension which may follow is usually transitory.

The usual dose of Piriton Injection for adults is 10–20 mg, but not more than 40 mg should be given per 24 hours.

In the event of a blood transfusion reaction a dose of 10–20 mg of Piriton should be given by the subcutaneous

route. This can be repeated to a total of 40 mg per 24 hours or oral forms of Piriton may be given until the symptoms subside. Though Piriton may be helpful in the prevention of delayed reactions to penicillin and other drugs it cannot be relied on to prevent anaphylactic reactions in patients known to be allergic to a particular drug. Piriton Injection 10 mg should be mixed, where practicable, with the drug to be injected, or injected separately by the intramuscular route immediately prior to injection of the other drug.

In the event of an anaphylactic reaction Piriton Injection 10–20 mg may be given by slow intravenous injection in addition to the emergency therapy of adrenaline, corticoids, oxygen and supportive therapy.

Contra-indications, warnings, etc

Contra-indications: There are no known definite contra-indications to therapy with Piriton.

Precautions: All antihistamines, given in effective dosage, may cause dizziness or drowsiness. In consequence, until the effect of the treatment is known, patients treated with Piriton should be warned not to take charge of vehicles or machinery. The sedative action of alcohol may be potentiated by antihistamines so that drowsiness can occur in patients not otherwise subject to it if alcohol is taken.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: Drowsiness and dizziness may occur. Some patients have reported a stinging or burning sensation at the site of injection. Rapid intravenous injection may cause transitory hypotension or CNS stimulation.

Overdosage: The estimated lethal dose of Piriton is 25–50 mg per kg body weight. Treatment should include gastric lavage if massive overdosage has been by the oral route. In the event of convulsions sedate with intramuscular paraldehyde. Severe respiratory depression may necessitate mechanical ventilation. Severe hypotension may require fluid replacement.

Pharmaceutical precautions *Storage:* There are no special storage conditions needed for Piriton Tablets. Piriton Spandets and Piriton Duolets require a cool dry place and Piriton Syrup a cool dark place. Piriton Injection should be protected from light.

Dilution: If it is necessary to dilute Piriton Syrup then the suitable diluent is unpreserved Syrup BP. The resulting mixture will keep for 14 days at room temperature.

Legal category Tablets P.
Spandets P.
Duolets P.
Syrup P.
Injection POM.

Package quantities Piriton Tablets are supplied in containers of 50 and 500.

Piriton Spandets are supplied in containers of 100.

Piriton Duolets are supplied in containers of 250.

Piriton Syrup is supplied in bottles of 150 ml.

Piriton Injection is supplied in boxes of 5 and 100 ampoules.

Further information No Piriton preparation contains tartrazine.

PROPADERM* CREAM PROPADERM* OINTMENT PROPADERM*-FORTE CREAM

Presentation Propaderm Cream, Ointment and Propaderm-Forte Cream are topical preparations of Beclomethasone Dipropionate BP. Beclomethasone Dipropionate BP is a potent anti-inflammatory steroid when applied topically to the skin.

Propaderm Cream: Beclomethasone Dipropionate BP 0.025% in a cream base.

Propaderm Ointment: Beclomethasone Dipropionate BP 0.025% in an ointment base.

Propaderm-Forte Cream: Beclomethasone Dipropionate BP 0.5% in a cream base.

Propaderm Cream and Propaderm-Forte Cream are all white in colour; Propaderm Ointment is yellowish.

Uses Propaderm Cream and Ointment are indicated for the local treatment of the various forms of eczema and dermatitis; the various forms of psoriasis; neurodermatoses including lichen simplex; intertrigo; discoid lupus erythematosus.

Propaderm Cream is preferred for weeping conditions or where the skin is usually moist or hairy.

Propaderm Ointment is suitable for dry, lichenified or scaly conditions or for use under occlusive dressings.

Propaderm-Forte Cream is used for resistant dermatoses, including pustular psoriasis of palms and soles, discoid lupus erythematosus, pemphigus erythematosus, mycosis fungoides, and some unusual conditions such as pretibial myxoedema, necrobiosis lipoidica, granuloma annulare.

Dosage and administration Propaderm preparations should be applied thinly over the whole of the affected area and gently rubbed in. Initial application is made twice daily, but when improvement is seen the intervals between applications may be extended and treatment eventually stopped. If the condition recurs, treatment should be re-instituted. Subsequent re-appearance of the condition is likely to be avoided by application of Propaderm every third or fourth day. Propaderm-Forte Cream may have to be applied three times daily in the initial stages until improvement is observed. The beneficial effect may be enhanced by preliminary use of hot soaks, or by intermittent applications of occlusive dressings.

Contra-indications, warnings, etc

Contra-indications: Propaderm should not be applied to the eyes. Infections of the skin should receive specific therapy, and the steroid withdrawn if the response is delayed. Propaderm is contra-indicated in the presence of tuberculosis of the skin, chickenpox, vaccinia, herpes virus infections and, also, for the treatment of varicose ulcers or any other stasis ulcers.

Precautions: When Propaderm, and in particular Propaderm-Forte Cream, is used under occlusive dressings over extensive areas there is the possibility of systemic absorption which could lead to side-effects and adrenal suppression. For this reason it is inadvisable to use more than 2 g of Propaderm-Forte Cream under occlusive dressings per application.

In infants there is the possibility of adrenal suppression with long-term application of Propaderm even without occlusion.

Topical administration of steroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: A single case of skin atrophy has been reported in a patient who had continuous therapy with Propaderm Ointment for 700 days. In the event of adverse effects occurring the preparation should be withdrawn.

Overdosage: Should systemic corticosteroid effects arise from excessive application of Propaderm preparations topical treatment should be discontinued. If adrenal function is impaired the patient will need to be protected from any harmful effects of stress with oral corticosteroid preparations until normal adrenal function is established.

Pharmaceutical precautions *Storage:* All Propaderm preparations should be stored at a temperature below 25°C and protected from light.

Dilution: Propaderm Cream may be diluted, if necessary, with Cetomacrogol Cream Formula A BPC. For Propaderm Ointment dilution can be effected with white soft paraffin.

Legal category POM.

Package quantities Propaderm Cream is available in tubes of 15 g and 50 g; Propaderm Ointment in tubes of 15 g and 50 g; and Propaderm-Forte Cream in tubes of 5 g.

Further information No Propaderm preparation contains lanolin or parabens.

PROPADERM*-A OINTMENT

Presentation Propaderm-A Ointment contains Beclomethasone Dipropionate BP 0.025% and Chlortetracycline Hydrochloride BP 3.0%. It is pale yellow in colour.

Beclomethasone Dipropionate BP is a potent anti-inflammatory steroid when applied topically to the skin. Chlortetracycline BP is a broad-spectrum antibiotic unlikely to cause skin sensitisation reactions.

Uses Propaderm-A Ointment is indicated for skin conditions which respond to therapy with an anti-inflammatory steroid where infection is present or is likely to occur, e.g. infective eczema of various types, seborrhoeic dermatitis and infective intertrigo. The combination of an anti-inflammatory steroid with an antibacterial is frequently preferred when occlusive dressings are used in conjunction with topical steroid therapy.

Occlusive dressings of an impermeable material such as polythene film can enhance the effect of Propaderm-A Ointment in certain resistant conditions such as fissured and lichenified eczema and neurodermatoses, hypertrophic lichen planus, chronic discoid lupus erythematosus, and psoriasis on the elbows and knees.

Dosage and administration Propaderm-A Ointment should be applied thinly over the whole of the affected area and gently rubbed in. Initially application should be twice daily, but when improvement is seen the intervals between applications may be extended and treatment eventually stopped. If the condition recurs, treatment should be re-instituted. Subsequent re-appearance of the condition can usually be avoided by application of Propaderm-A Ointment every third or fourth day.

Contra-indications, warnings, etc

Contra-indications: Propaderm-A Ointment should not be applied to the eyes. Infections of the skin failing to respond necessitate withdrawal of Propaderm-A and use of specific therapy. Propaderm is contra-indicated in the presence of tuberculosis of the skin, chickenpox, vaccinia, herpes virus infections, fungal infections and, also, for the treatment of varicose ulcers or any other stasis ulcers.

Precautions: When Propaderm-A Ointment is used under occlusive dressings over extensive areas there is the possibility that this could lead to side-effects and adrenal suppression. In infants long-term continuous topical steroid therapy could cause adrenal suppression even without occlusion. Topical administration of steroids to pregnant animals can cause foetal abnormalities. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Chlortetracycline very occasionally causes sensitisation. A single case of skin atrophy has been reported in a patient who had continuous therapy with Propaderm Ointment for 700 days. If adverse effects occur the preparation should be withdrawn.

Overdosage: Should systemic corticosteroid effects arise from excessive application of Propaderm preparations topical treatment should be discontinued. If adrenal function is impaired the patient will need to be protected from any harmful effects of stress with oral corticosteroid preparations until normal adrenal function is established.

Pharmaceutical precautions *Storage:* Store at a temperature not exceeding 25°C and protect from light.

Dilution: Propaderm-A Ointment may be diluted, if necessary, with white soft paraffin.

Legal category POM.

Package quantities Propaderm-A Ointment is available in tubes of 15 g and 50 g.

Further information No lanolin or parabens included in the formula of Propaderm-A Ointment.

Product licence number 0045/5006.

PROPADERM*-C CREAM PROPADERM*-C OINTMENT

Presentation Propaderm-C Cream and Ointment are topical preparations of Beclomethasone Dipropionate BP and Clotrimazole BP.

Propaderm-C Cream contains Beclomethasone Dipropionate BP 0.025% and Clotrimazole BP 3.0%. Propaderm-C Ointment contains Beclomethasone Dipropionate BP 0.025% and Clotrimazole BP 3.0%. Both Propaderm-C Cream and Ointment are pale yellow in colour.

Beclomethasone Dipropionate BP is a potent anti-inflammatory steroid when applied topically to the skin. Clioquinol BP has a wide range of antibacterial and antifungal activity.

Uses Propaderm -C Cream and Ointment are indicated for skin conditions which respond to topical steroid therapy where infection is present or is likely to occur, particularly where the infection is fungal.

Propaderm-C Cream is preferred for weeping conditions or where the skin is usually moist or hairy. Propaderm-C Ointment is suitable for dry, lichenified or scaly conditions or for use under occlusive dressings.

Dosage and administration Propaderm-C should be applied thinly over the whole of the affected area and gently rubbed in. Initial application is made twice daily, but when improvement is seen the intervals between the applications may be extended and treatment eventually stopped.

If the condition recurs, treatment should be reinstated. Subsequent re-appearance of the condition can usually be avoided by application of Propaderm-C every third or fourth day.

Contra-indications, warnings, etc

Contra-indications: Propaderm-C should not be applied to the eyes. Infections of the skin failing to respond necessitate withdrawal of Propaderm-C and use of specific therapy. Propaderm is contra-indicated in the presence of tuberculosis of the skin, chickenpox, vaccinia, herpes virus infections and, also, for the treatment of varicose ulcers or any other stasis ulcers.

Precautions: When Propaderm-C is used under occlusive dressings over extensive areas there is the possibility of systemic absorption which could lead to side-effects and adrenal suppression.

In infants there is the possibility of adrenal suppression with long-term application of Propaderm-C even without occlusion.

Topical administration of steroids to pregnant animals can cause foetal abnormalities. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Sensitisation reactions to clioquinol have been reported. Where there is unexplained relapse with continued treatment this possibility may be responsible.

A single case of skin atrophy has been reported in a patient who had continuous therapy with Propaderm Ointment for 700 days. If adverse effects occur the preparation should be withdrawn.

Overdosage: Should systemic corticosteroid effects arise from excessive application of Propaderm preparations topical treatment should be discontinued. If adrenal function is impaired the patient will need to be protected from any harmful effects of stress with oral corticosteroid preparations until normal adrenal function is established.

Pharmaceutical precautions *Storage:* Store at a temperature below 25°C and protect from light.

Dilution: Propaderm-C Cream may be diluted, if necessary, with Cetomacrogol Cream Formula A BPC and Propaderm-C Ointment with white soft paraffin.

Legal category POM.

Package quantities Propaderm-C Cream and Ointment are available in tubes of 15 g.

Further information Propaderm-C Cream and Ointment do not contain lanolin or parabens.

Propaderm-C Ointment 0045/5007

STERISPON*

Presentation Sterispon is Absorbable Gelatin Sponge BP and an effective haemostatic. It is not friable and may be cut into any desired shape or size or moulded with the fingers. Sterispon is prepared sterile and specially packed ready for use in the operating theatre. It is white in colour.

Uses For control of capillary oozing and venous bleeding in most forms of surgery (for exceptions, see **Contra-indications**). Sterispon may be used as a material for the obliteration of surgical 'dead spaces'.

Dosage and administration The sponge should be removed from the packings with sterile forceps and, if necessary, cut into pieces of the desired size and shape. It may be used in the dry state or moistened with normal saline. If the latter state is required, place the sponge in normal saline and remove the air by gentle squeezing before use. Sterispon is applied to the site of bleeding with sufficient pressure to enable adherence of the sponge and control of bleeding. Since Sterispon is completely absorbed by normal phagocytosis it is usually left *in situ* and the wound closed.

Contra-indications, warnings, etc

Contra-indications: Sterispon is contra-indicated for use in stapedectomy or other aural surgery where it could come into contact with fluid from the internal ear. In ophthalmic surgery it is inadvisable to use Sterispon in operations where the aqueous or vitreous humours are exposed.

Precautions: It is not advisable to apply Sterispon in the usual manner in the presence of infection, but it may be used to control haemorrhage if treated as a removable pack.

Side-effects: None.

Overdosage: Not applicable.

Pharmaceutical precautions Sterispon cannot be re-sterilised once the container has been opened without alteration to the properties of the sponge.

Storage: Store at a temperature not exceeding 25°C.

Legal category P.

Package quantities Sterispon is supplied sterile in the following sizes:

- | | |
|------------|--|
| Size No. 1 | Strips, 6 × 2 × 0.7 cm, in glass tubes each containing one piece. |
| Size No. 2 | Strips, 20 × 10 × 0.1 cm, in glass tubes each containing one piece. |
| Size No. 3 | Thin wafers, 2 × 2 × 0.1 cm, in glass tubes each containing six pieces. |
| Size No. 4 | Strips, 10 × 10 × 0.5 cm, in envelopes containing one piece. |
| Size No. 5 | For dental use. Pieces, 2 × 2 × 1 cm, in glass tubes each containing six pieces. |

Further information Nil.

Product licence number 0045/5063.

TRANDATE* TABLETS 100 mg
TRANDATE* TABLETS 200 mg
TRANDATE* TABLETS 400 mg

Presentation 1. *Trandate Tablets 100 mg*: Circular, orange coloured, film-coated biconvex tablets, each containing labetalol hydrochloride 100 mg, marked TRANDATE 100AH on one face.

2. *Trandate Tablets 200 mg*: Circular, orange coloured, film-coated biconvex tablets, each containing labetalol hydrochloride 200 mg, marked TRANDATE 200AH on one face.

3. *Trandate Tablets 400 mg*: Circular, orange coloured, film-coated biconvex tablets, each containing labetalol hydrochloride 400 mg, marked TRANDATE 400AH on one face.

Labetalol hydrochloride is 2-hydroxy-5-[1-hydroxy-2-(1-methyl-3-phenylpropylamino) ethyl] benzamide hydrochloride.

Uses *Indications*: Trandate Tablets are indicated for the treatment of all forms of hypertension, including the hypertensions of pregnancy, and all grades of hypertension (mild, moderate and severe) when oral antihypertensive therapy is desirable.

Mode of action: Trandate lowers the blood pressure primarily by blocking alpha-adrenoceptors in peripheral arterioles and thereby reducing the peripheral resistance. Concurrent beta-blockade protects the heart from the reflex sympathetic drive normally induced by peripheral vasodilatation. Cardiac output is not significantly reduced at rest or after moderate exercise. Increases in systolic pressure during exercise are, however, reduced after Trandate; corresponding changes in the diastolic pressure are essentially normal. All these effects would be expected to benefit hypertensive patients.

Dosage and administration *Adults*: Treatment may start with one 200 mg tablet twice daily but in some patients, including those already being treated with antihypertensive drugs, the elderly and those of low bodyweight, one 100 mg tablet twice daily is more appropriate. If the blood pressure is not controlled by the initial dosage, increases should be made at intervals of about 14 days. By prescribing tablets of increasing strength, the dose can be maintained at one tablet twice daily until a total daily dose of 800 mg is reached. Daily doses of up to 2,400 mg have been given in the treatment of severe and refractory hypertension. In such patients it is preferable to administer Trandate three or four times daily.

Satisfactory control of blood pressure will be obtained in many patients at a total daily dosage of 400 mg (one 200 mg tablet twice daily).

In severe hypertension, particularly that of pregnancy, the dosage may be increased on a daily basis until adequate control of blood pressure is obtained.

Tablets should be taken with food.

For hospital in-patients daily increases in dosage may be made if the need to reduce blood pressure is urgent. If it is necessary to reduce the blood pressure rapidly in very severe hypertension, Trandate Injection is indicated (see Data Sheet for Trandate Injection).

Children: Not applicable.

Use with other agents: Hypertension is usually controlled by Trandate alone. Diuretic therapy is not usually necessary in patients receiving Trandate Tablets, but may be introduced or continued if required. Diuretics

usually increase the antihypertensive action of Trandate.

If Trandate Tablets are prescribed together with another antihypertensive drug, such as methyldopa or clonidine, an additive effect may be expected in patients who are responsive to both drugs. When transferring patients from other drugs, Trandate Tablets should be introduced as recommended above and the dosage of the existing therapy progressively decreased.

Abrupt withdrawal of clonidine or beta-adrenoceptor blockers is undesirable.

Contra-indications, warnings, etc

Contra-indications: There are no known absolute contra-indications to the use of Trandate Tablets.

Warning: There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable.

Precautions: Heart failure should be controlled with digitalis and diuretic therapy before treatment is initiated. Trandate should not normally be given to patients with digitalis-resistant heart failure or atrio-ventricular block.

Patients with severe liver damage may have higher than normal plasma concentrations of labetalol due to reduced metabolism. Consequently, patients with liver disease may require lower than the usual doses of Trandate to control their blood pressure.

Caution must be observed if Trandate is used to treat asthmatic patients or individuals prone to bronchospasm. Any resultant bronchospasm may be controlled by an inhaled selectively-acting bronchodilator such as salbutamol; the required dose may be greater than the normal anti-asthmatic dose. If further treatment is required, intravenous atropine 1 mg should be given.

It is not necessary to discontinue Trandate Tablets in patients requiring anaesthesia but they should be given intravenous atropine prior to induction; the effect of halothane on blood pressure may be enhanced by Trandate.

Although no teratogenic effects have been demonstrated in animals the unnecessary use of Trandate during the first trimester of pregnancy is undesirable.

Trandate crosses the placental barrier and the possibility of the consequences of alpha- and beta-adrenoceptor blockade in the foetus and neonate (e.g., bradycardia and hypoglycaemia) should be borne in mind. Experience has shown this to have been an exceptionally rare occurrence.

Trandate is excreted in breast milk. No adverse effects in breast feeding infants have been reported.

Side-effects: Where side effects to Trandate have occurred they have usually done so during the first weeks of treatment and have been transient. Symptoms tend to have been similar in nature to those often observed in untreated hypertensive patients and have included headache, tiredness, dizziness, depressed mood and lethargy.

If the initial dosage is too high, or the dose increased too rapidly, symptoms of postural hypotension may occur. These are uncommon, except at very high doses, if the drug is used as recommended.

In a few patients certain other side-effects have occurred which appear to be more directly related to Trandate treatment. These include difficulty in micturition, epigastric pain, nausea and vomiting.

Again, in a few patients a tingling sensation in the scalp associated with Trandate treatment has been reported. It usually occurs early in the treatment and tends to be transient in nature.

In a very small number of patients a lichenoid rash has appeared during Trandate treatment but has disappeared on withdrawing treatment. Other skin rashes not necessarily induced by Trandate treatment have been reported. Blurring of vision, eye irritation and cramps have also been reported but have been difficult to relate directly to Trandate treatment.

Overdosage: Overdosage with Trandate causes excessive hypotension, which is posture sensitive and sometimes, excessive bradycardia. Patients should be laid supine and their legs raised if necessary to improve the blood supply to the brain. Atropine 3 mg should be given intravenously to relieve bradycardia.

Massive overdosage with Trandate in man has not been reported but profound cardiovascular effects are to be expected. Atropine at least 3 mg intravenously should always be given. Gastric lavage or induced emesis is warranted for a few hours after oral ingestion of the drug. If further measures are required to obtain adequate circulatory function, intravenous noradrenaline may be preferable to isoprenaline, the established pharmacological treatment for excessive cardiac beta-blockade. The recommended starting dose of noradrenaline in patients is 5–10 mcg by intravenous injection repeated as required according to the response. Alternatively, noradrenaline may be infused at a rate of 5 mcg per minute until a satisfactory response is achieved.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities

Trandate Tablets 100 mg: Containers of 50 and 250.

Trandate Tablets 200 mg: Containers of 50 and 250.

Trandate Tablets 400 mg: Containers of 50 and 250.

Further information Trandate does not adversely affect renal function and is a particularly suitable drug for use in hypertensive patients with renal disease. The metabolites of Trandate are excreted in the faeces as well as the urine and so the drug is unlikely to accumulate in the body even in renal failure.

In non-pregnant patients the half-life of Trandate in plasma is about four hours and somewhat less in pregnancy. Only about 50% of Trandate in the blood is protein bound.

Trandate fluoresces in alkaline solution at an excitation wavelength of 334 nm and a fluorescence wavelength of 412 nm and may therefore interfere with the assays of certain fluorescent substances.

TRANDATE* INJECTION

Presentation *Trandate Injection:* 20 ml ampoules each containing 100 mg (5 mg/ml) labetalol hydrochloride in an aqueous colourless solution.

Labetalol hydrochloride is 2-hydroxy-5-[1-hydroxy-2-(1-methyl-3-phenylpropylamino) ethyl] benzamide hydrochloride.

Uses *Indications:* Trandate Injection is indicated when rapid control of blood pressure is essential in severely hypertensive patients including severe hypertension of pregnancy and for use in anaesthesia where a hypotensive technique is indicated.

Mode of action: Trandate lowers the blood pressure primarily by blocking alpha-adrenoceptors in peripheral arterioles and thereby reducing the peripheral resistance.

Concurrent beta-blockade protects the heart from reflex sympathetic drive normally induced by peripheral vasodilatation. Cardiac output is not significantly reduced at rest or after moderate exercise. Increases in systolic pressure during exercise are, however, reduced after Trandate; corresponding changes in diastolic pressure are essentially normal. All these effects would be expected to benefit hypertensive patients.

Dosage and administration *Adults:* Trandate Injection is intended for intravenous use in hospitalised patients. The plasma concentrations achieved after intravenous doses of Trandate in severe hypertension are substantially greater than those following oral administration of the drug and provide the greater degree of blockade of alpha-adrenoceptors necessary to control the more severe disease. Patients should, therefore, always receive the drug whilst in the supine or left lateral position.

Raising the patient into the upright position, within three hours of intravenous Trandate administration, should be avoided since excessive postural hypotension may occur.

If it is essential to reduce the blood pressure quickly, as, for example, in hypertensive encephalopathy, a dose of 50 mg of Trandate should be given by intravenous injection over a period of at least one minute. If necessary, doses of 50 mg may be repeated at five minute intervals until a satisfactory response occurs. The total dose should not exceed 200 mg. After bolus injection, the maximum effect usually occurs within five minutes and the effective duration of action is usually about six hours but may be as long as eighteen hours.

An alternative method for administering Trandate is intravenous infusion of a solution made by diluting the contents of two ampoules (200 mg) to 200 ml with Sodium Chloride and Dextrose Injection BP or 5% Dextrose Intravenous Infusion BP. The resultant infusion solution contains 1 mg/ml of Trandate. It should be administered using a paediatric giving set fitted with a 50 ml graduated burette to facilitate dosage.

In the hypertensions of pregnancy, the infusion can be started at the rate of 20 mg per hour and this dose may be doubled every thirty minutes until a satisfactory reduction in blood pressure has been obtained or a dosage of 160 mg per hour is reached. Occasionally, higher doses may be necessary.

In hypertension due to other causes the rate of infusion of Trandate should be about 2 mg (2 ml of infusion solution) per minute, until a satisfactory response is obtained; the infusion should then be stopped. The effective dose is usually in the range of 50–200 mg, depending on the severity of the hypertension. For most patients it is unnecessary to administer more than 200 mg but larger doses may be required especially in patients with phaeochromocytoma. The rate of infusion may be adjusted according to the response, at the discretion of the physician. The blood pressure and pulse rate should be monitored throughout the infusion.

It is desirable to monitor the heart rate after injection and during infusion. In most patients, there is a small

decrease in the heart rate; severe bradycardia is unusual but may be controlled by injecting atropine 1–2 mg intravenously. Respiratory function should be observed particularly in patients with any known impairment.

Once the blood pressure has been adequately reduced, maintenance therapy with Trandate Tablets should be instituted with a starting dose of one 200 mg tablet twice daily. (See Trandate Tablets Data Sheet for further details.) Trandate Injection has been administered to patients with uncontrolled hypertension already receiving other hypotensive agents, including beta-blocking drugs, without adverse effects.

In hypotensive anaesthesia induction should be with standard agents (e.g., sodium thiopentone) and anaesthesia maintained with nitrous oxide and oxygen with or without halothane. The recommended starting dose of Trandate Injection is 10–20 mg intravenously depending on the age and condition of the patient. Patients for whom halothane is contra-indicated usually require a higher initial dose of Trandate (25–30 mg). If satisfactory hypotension is not achieved after five minutes, increments of 5–10 mg should be given until the desired level of blood pressure is attained.

Halothane and Trandate act synergistically therefore the halothane concentration should not exceed 1–1.5% as profound falls in blood pressure may be precipitated.

Following Trandate Injection the blood pressure can be quickly and easily adjusted by altering the halothane concentration and/or adjusting table tilt. The mean duration of hypotension following 20–25 mg of Trandate is fifty minutes.

Hypotension induced by Trandate Injection is readily reversed by atropine 0.6 mg and discontinuation of halothane.

Tubocurarine and pancuronium may be used when assisted or controlled ventilation is required. IPPV may further increase the hypotension resulting from Trandate Injection and/or halothane.

Children: Not applicable.

Contra-indications, warnings, etc

Contra-indications: There are no known absolute contra-indications to the use of Trandate Injection.

Precautions: Trandate Injection should not normally be given to patients with digitalis-resistant heart failure or atrio-ventricular block.

Caution must be observed if Trandate is used to treat asthmatic patients or individuals prone to bronchospasm. Any resultant bronchospasm may be controlled by an inhaled selectively-acting bronchodilator such as salbutamol; the required dose may be greater than the normal anti-asthmatic dose. If further treatment is required, intravenous atropine 1 mg should be given.

It is not necessary to discontinue Trandate therapy in patients requiring anaesthesia but they should be given intravenous atropine prior to induction; the effect of halothane on blood pressure may be enhanced by Trandate.

During anaesthesia Trandate may mask the compensatory physiological responses to sudden haemorrhage (tachycardia and vasoconstriction). Close attention must therefore be paid to blood loss and the blood volume maintained.

Although no teratogenic effects have been demonstrated in animals the unnecessary use of Trandate during the first trimester of pregnancy is undesirable. Trandate crosses the placental barrier and the possibility of the consequences of alpha- and beta-adrenoceptor

blockade in the foetus and neonate (e.g., bradycardia and hypoglycaemia) should be borne in mind. Experience has shown this to have been an exceptionally rare occurrence. Trandate is excreted in breast milk. No adverse effects in breast feeding infants have been reported.

Side-effects: Trandate Injection is usually well tolerated. Excessive postural hypotension may occur if patients are allowed to assume the upright position within three hours of receiving Trandate Injection.

Overdosage: Overdosage with Trandate causes excessive hypotension, which is posture sensitive, and sometimes excessive bradycardia. Patients should be laid supine and their legs raised if necessary to improve the blood supply to the brain. Atropine 3 mg should be given intravenously to relieve bradycardia.

Massive overdosage with Trandate in man has not been reported, but profound cardiovascular effects are to be expected. Atropine at least 3 mg intravenously should always be given. If further measures are required to obtain adequate circulatory function, intravenous noradrenaline may be preferable to isoprenaline, the established pharmacological treatment for excessive cardiac beta-blockade. The recommended starting dose of noradrenaline in patients is 5–10 mcg by intravenous injection repeated as required according to the response. Alternatively noradrenaline may be infused at a rate of 5 mcg per minute until a satisfactory response is achieved.

Pharmaceutical precautions Protect from light.

TRIPTAFEN*-MINOR TRIPTAFEN*-DA

Presentation These are combined preparations of Amitriptyline Hydrochloride BP and Perphenazine BP.

Triptafen-Minor Tablets each contain Amitriptyline Hydrochloride BP 10 mg and Perphenazine BP 2 mg. Sugar-coated red tablets coded AH/2D.

Triptafen-DA Tablets each contain Amitriptyline Hydrochloride BP 25 mg and Perphenazine BP 2 mg. Sugar-coated, pink tablets coded AH/1D.

Uses Amitriptyline Hydrochloride BP is a tricyclic compound with antidepressive activity. Perphenazine is a piperazine derivative of phenothiazine which has potent tranquillising activity. Both Triptafen preparations are primarily indicated for combined depression with anxiety.

Triptafen-Minor: Anxiety states where depression may be a factor; psychosomatic disorders; the initiation of Triptafen treatment of depression, and continuation treatment of depressed patients requiring lower doses of amitriptyline.

Triptafen-DA: Depression, psychoneurosis, anxiety, psychosomatic illness, climacteric disorders associated with anxiety and depression, withdrawal syndrome in chronic alcoholism.

Dosage and administration Both Triptafen preparations are administered orally.

Adults: Triptafen-Minor: 1 tablet three times daily with a further tablet at night if necessary.

Triptafen-DA: 1 tablet three times daily with a fourth dose at night, if necessary.

With both Triptafen preparations the dosage may be adjusted to suit the needs of the individual patient with interchange of the preparation according to the requirements of tranquilliser or antidepressive medication.

Children: Triptafen preparations are not suitable for administration to children under 14 years of age.

Contra-indications, warnings, etc

Contra-indications: Glaucoma; urinary retention; congestive heart failure; coronary artery disease; epilepsy; severely impaired liver function; concurrent administration of other antidepressive drugs, particularly monoamine oxidase inhibitors (MAOIs). No Triptafen preparation should be given to patients with leucopenia or in association with drugs liable to cause bone-marrow depression.

Precautions: The Triptafen range of preparations should not be given in conjunction with MAOIs and, because of the persistent action of the latter, an interval of at least 14 days should be allowed to elapse between withdrawal of an MAOI and introduction of a Triptafen. Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: The side-effects of the Triptafen range are those of the drugs which they contain. Amitriptyline has atropine-like and sedative actions and may therefore give rise to drowsiness, dry mouth, blurred vision, tachycardia and, more rarely, insomnia. Perphenazine may cause mild drowsiness and a slight fall in blood pressure; in higher dosage, tremor and extrapyramidal effects may occur. Idiosyncratic side-effects, such as pruritus, nausea, diarrhoea and indigestion, may occur.

Persistent oral dyskinesia has been reported occasionally, particularly in elderly female patients, after long-term treatment with potent phenothiazine drugs including perphenazine.

Overdosage: Gastric lavage should be performed as soon as possible. If convulsions occur or threaten they should be controlled with standard methods, but barbiturates should be avoided. In severe cases haemodialysis may be performed if practicable. It is recommended that patients who have taken an overdose of Triptafen should

be observed for at least 48 hours even if symptoms are not severe.

Pharmaceutical precautions *Storage:* No special storage conditions are necessary for either of the Triptafen preparations.

Legal category POM.

Package quantities Triptafen-Minor Tablets and Triptafen-DA Tablets are issued in cartons each containing 100 tablets in 10 foil strips of 10 (5 × 2) tablets.

Further information Nil.

Triptafen-DA Tablets	0045/5087

VENTOLIN* INHALER

Presentation Metered-dose aerosol delivering 100 mcg Salbutamol BP per actuation, with a specially designed actuator.

Uses Salbutamol BP is a beta-adrenergic stimulant which has a highly selective action on the receptors in bronchial muscle and, in therapeutic dosage, little or no action on the cardiac receptors.

Salbutamol is also highly active in preventing antigen-induced release of histamine and slow-reacting substance of anaphylaxis, SRS(A), from mast cells in human lung sensitised with IgE antibody. Such Type I hypersensitivity reactions are generally considered to be the primary triggers of the allergic asthma syndrome.

Ventolin Inhaler is, therefore, indicated both for the treatment and prophylaxis of bronchial asthma, and also for the treatment of other conditions, such as bronchitis and emphysema, with associated reversible airways obstruction. Because Ventolin Inhaler is long-acting it is ideally suited for routine maintenance therapy in chronic asthma and chronic bronchitis. The inhaler drug-delivery system, using salbutamol in microgram dosage, avoids the skeletal muscle tremor sometimes associated with oral therapy.

Ventolin Inhaler acts rapidly and may be used when necessary to relieve attacks of acute dyspnoea. Doses may be taken prophylactically before exertion or to prevent exercise-induced asthma.

Because of its selective action on the bronchi and its lack of effects on the cardiovascular system, Ventolin Inhaler is suitable for treating bronchospasm in patients with co-existing heart disease or hypertension, including those taking beta-blocking drugs which often impair respiratory function.

Dosage and administration **Adults:** For the relief of acute bronchospasm and for managing intermittent episodes of asthma, one or two inhalations may be administered as a single dose. The recommended dose for chronic maintenance or prophylactic therapy is two inhalations three or four times a day.

To prevent exercise-induced bronchospasm, two inhalations should be taken before exertion.

Children: One inhalation is the recommended dose for the relief of acute bronchospasm, in the management of episodic asthma or before exercise.

One inhalation should be administered three or four times a day for routine maintenance or prophylactic therapy. These doses may be increased to two inhalations, if necessary.

For optimum results, in most patients, Ventolin Inhaler should be used regularly.

The bronchodilator effect of each administration of inhaled Ventolin lasts at least four hours except in patients whose asthma is worsening. Such patients should be warned not to increase their usage of inhaler but should seek medical advice in case treatment with a glucocorticoid is indicated.

Contra-indications, warnings, etc

Contra-indications: Although intravenous salbutamol and occasionally salbutamol tablets are used to prevent premature labour Ventolin preparations should not be used for threatened abortion during the first or second trimesters.

Precautions: In the event of a previously effective dose of Ventolin Inhaler failing to give relief for at least three hours, the patient should be advised to seek medical advice in order that any necessary additional steps may be taken. Ventolin should be administered cautiously to patients suffering from thyrotoxicosis.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: No important side-effects have been reported following Ventolin Inhaler therapy.

Overdosage: The preferred antidote for overdosage with Ventolin Inhaler is a cardioselective beta-blocking agent, but beta-blocking drugs should be used with caution in patients with a history of bronchospasm.

Pharmaceutical precautions *Storage:* Ventolin Inhaler should be stored in a cool place, protected from frost and direct sunlight. The canister should not be broken, punctured or burnt, even when apparently empty.

Legal category POM.

Package quantities Ventolin Inhaler is a metered-dose aerosol with a specially designed actuator. Each canister provides 200 inhalations.

Further information Ventolin does not cause difficulty in micturition because, unlike sympathomimetic drugs such as ephedrine, it does not stimulate alpha-adrenoceptors. Ventolin is not contra-indicated in patients under treatment with monoamine oxidase inhibitors (MAOIs).

Product licence number 0045/5022.

VENTOLIN® PARENTERAL PREPARATIONS

VENTOLIN® INJECTION 0.5 mg in 1 ml

(500 mcg/ml)

VENTOLIN® INJECTION 0.25 mg in 5 ml

(50 mcg/ml)

VENTOLIN® SOLUTION FOR INTRAVENOUS INFUSION 5 mg in 5 ml (1,000 mcg/ml)

Presentation Ventolin Injection 0.5 mg in 1 ml (500 mcg/ml) is presented in ampoules of 1 ml each containing 0.5 mg Salbutamol BP as Salbutamol Sul-

phate BP, in a sterile isotonic solution adjusted to pH 3.5 with sulphuric acid.

Ventolin Injection 0.25 mg in 5 ml (50 mcg/ml) is presented as ampoules of 5 ml each containing 0.25 mg Salbutamol BP as Salbutamol Sulphate BP, in a sterile isotonic solution adjusted to pH 3.5 with sulphuric acid.

Ventolin Solution For Intravenous Infusion 5 mg in 5 ml (1,000 mcg/ml) is presented as ampoules of 5 ml each containing 5 mg Salbutamol BP as Salbutamol Sulphate BP, in a sterile isotonic solution adjusted to pH 3.5 with sulphuric acid.

The ampoules are of clear, neutral glass and the solution is colourless or faintly straw coloured.

Uses Salbutamol BP is a beta-adrenergic stimulant that has a selective action on the beta₂-adrenoceptors in the bronchi and uterus and much less action on the beta₁-adrenoceptors in the heart.

Ventolin parenteral preparations are indicated for two distinct clinical situations:

1. For the relief of severe bronchospasm associated with asthma or bronchitis and for the treatment of status asthmaticus.
2. For the management of uncomplicated premature labour in the last trimester of pregnancy.

Dosage and administration 1. *In severe bronchospasm and status asthmaticus*

Subcutaneous route: Adults: 500 mcg (8 mcg/kg body weight) and repeated every four hours as required.

Intramuscular route: Adults: 500 mcg (8 mcg/kg body weight) and repeated every four hours as required.

Intravenous route: Adults: 250 mcg (4 mcg/kg body weight) injected slowly. If necessary the dose may be repeated. Ventolin Injection 0.25 mg in 5 ml (50 mcg/ml) is a suitably dilute preparation for slow intravenous injection, but if Ventolin Injection 0.5 mg in 1 ml (500 mcg/ml) is used the injection may be facilitated by dilution with Water for Injections BP.

Infusion: In status asthmaticus, infusion rates of 3–20 mcg per minute are generally adequate, but in patients with respiratory failure higher dosage has been used with success. A starting dose of 5 mcg per minute is recommended with appropriate adjustments in dosage according to patient response.

A suitable solution for infusion may be prepared by diluting 5 ml of Ventolin Solution. For Intravenous Infusion in 500 ml of an infusion solution such as Sodium Chloride and Dextrose Injection BP to provide a salbutamol dose of 10 mcg/ml of solution.

Children: At present there is insufficient evidence to recommend a dosage regimen for routine use in children.

2. In the management of premature labour

For this indication Ventolin Solution for Intravenous Infusion is recommended using a solution prepared as in 1. above.

Infusion rates of 10–45 mcg per minute are generally adequate to control uterine contractions, but greater or lesser infusion rates may be required according to the strength and frequency of contractions. A starting rate of 10 mcg per minute is recommended, increasing the rate at 10-minute intervals until there is evidence of patient response shown by diminution in strength, frequency or duration of contractions. Thereafter the infusion rate may be increased slowly until contractions cease. The maternal pulse rate should be monitored and

the infusion rate adjusted to avoid excessive maternal heart rates (above 140 beats per minute). Once uterine contractions have ceased the infusion rate should be maintained at the same level for one hour and then reduced by 50% decrements at six-hourly intervals. Treatment may be continued orally with Ventolin Tablets 4 mg given three or four times daily.

As an alternative procedure or to counteract inadvertent overdosage with oxytocic drugs Ventolin Injection may be administered as a single injection by the intravenous or intramuscular routes. The usual recommended dose is 100–250 mcg of salbutamol. The dose may be repeated according to the response of the patient.

Note. The contents of the ampoules of Ventolin Solution For Intravenous Infusion must not be injected undiluted.

Ventolin parenteral preparations should not be administered in the same syringe or infusion as any other medication.

Contra-indications, warnings, etc

Contra-indications: Though Ventolin parenteral preparations are recommended for the prevention of uncomplicated premature labour their use in premature labour associated with toxæmia of pregnancy or ante-partum haemorrhage from whatever cause is contra-indicated. Ventolin preparations should not be used for threatened abortion during the first or second trimesters of pregnancy.

Precautions: The use of Ventolin parenteral preparations in the treatment of severe bronchospasm or status asthmaticus does not obviate the requirement for glucocorticoid steroid therapy as appropriate. When practicable, administration of oxygen concurrently with parenteral Ventolin is recommended, particularly when it is given by intravenous infusion to hypoxic patients. In common with other beta-adrenoceptor agonists, Ventolin can induce reversible metabolic changes. These are most pronounced during infusions of the drug when an increase in blood glucose is likely. The diabetic patient may be unable to compensate for this and the development of ketoacidosis has been reported. Concurrent administration of corticosteroids can exaggerate this effect. Therefore diabetic patients and those concurrently receiving corticosteroids should be monitored frequently during intravenous infusion of Ventolin so that remedial steps (e.g. an increase in insulin dosage) can be taken to counter any metabolic change occurring. For these patients it may be preferable to dilute Ventolin Solution For Intravenous Infusion in Sodium Chloride Injection BP rather than Sodium Chloride and Dextrose Injection BP.

Ventolin should be administered cautiously to patients suffering from thyrotoxicosis. In patients being treated to inhibit uterine contractions in premature labour by intravenous infusion of salbutamol, increases in maternal heart rate of the order of 20–50 beats per minute usually accompany the infusion. The maternal pulse rate should be monitored and not normally allowed to exceed a steady rate of 140 beats per minute. Maternal blood pressure may fall slightly during the infusion, the effect being greater on diastolic than on systolic pressure. Falls in diastolic pressure are usually within the range of 10–20 mmHg. The effect of infusion on foetal heart rate is less marked, but increases of up to 20 beats per minute may occur. In the treatment of premature labour before Ventolin parenteral preparations are given to any patient with known heart disease, an adequate assessment of the patient's cardiovascular status should be made by a

physician experienced in cardiology. Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: Intramuscular use of the undiluted injection may produce slight pain or stinging. Enhancement of physiological tremor may occur with Ventolin. This effect is caused by a direct action on skeletal muscle and is common to all beta-adrenergic stimulants.

Ventolin parenteral preparations may dilate some peripheral arterioles leading to a small reduction in arterial pressure and a compensatory increase in cardiac rate. Increases in heart rate are more likely to occur in patients with normal heart rates and these increases are dose-dependent. In patients with pre-existing sinus tachycardia, especially those in status asthmaticus, the heart rate tends to fall as the condition of the patient improves.

In the management of premature labour, intravenous infusion of Ventolin has occasionally been associated with nausea, vomiting and headaches.

Overdosage: The preferred antidote for overdosage with Ventolin is a cardioselective beta-blocking agent. Beta-blocking drugs should be used with caution in patients with a history of bronchospasm.

Pharmaceutical precautions Ventolin parenteral preparations may be diluted with Water for Injections BP, Sodium Chloride Injection BP, Sodium Chloride and Dextrose Injection BP or Dextrose Injection BP. These are the only recommended diluents.

Ventolin parenteral preparations should not be administered in the same syringe or infusion as any other medication.

The contents of the ampoule of Ventolin Solution For Intravenous Infusion must not be injected in the undiluted form; the concentration should be reduced by at least 50% before administration.

Storage: Ventolin parenteral preparations should be protected from light and stored at a temperature below 30°C.

Legal category POM.

Package quantities Ventolin Injection 0.5 mg in 1 ml (500 mcg/ml) is available in boxes of 5 ampoules.

Ventolin Injection 0.25 mg in 5 ml (50 mcg/ml) is available in boxes of 10 ampoules.

Ventolin Solution For Intravenous Infusion 5 mg in 5 ml (1,000 mcg/ml) is available in boxes of 10 ampoules.

Further information Ventolin does not cause difficulty in micturition because, unlike sympathomimetic drugs such as ephedrine, it does not stimulate alpha-adrenoceptors. Ventolin is not contra-indicated in patients under treatment with monoamine oxidase inhibitors (MAOIs).

Ventolin Injection 0.25 mg in 5 ml (50 mcg/ml)	0045/0108
Ventolin Solution for Intravenous Infusion 5 mg in 5 ml (1,000 mcg/ml)	0045/0103

VENTOLIN® RESPIRATOR SOLUTION

Presentation Ventolin Respirator Solution is an aqueous colourless solution of Salbutamol Sulphate BP

adjusted with acid to pH 3.5. The concentration, which is expressed in terms of Salbutamol BP, is 0.5% or 5 mg per ml of solution.

Uses Ventolin Respirator Solution is indicated for the treatment of severe acute asthma (status asthmaticus) and other forms of bronchospasm.

Dosage and administration 1. *By intermittent administration. Adults:* Ventolin Respirator Solution 0.5–1.0 ml (2.5–5.0 mg of salbutamol) should be diluted to a final volume of 2.0 or 2.5 ml with sterile distilled water or normal saline for injection. The resulting solution is inhaled from a suitably driven nebuliser until aerosol generation ceases. Using a correctly matched nebuliser and driving source this should take about ten minutes.

Ventolin Respirator Solution may be used undiluted for intermittent administration. For this, 2.0 ml of Ventolin Respirator Solution (10.0 mg salbutamol) is placed in the nebuliser and the patient allowed to inhale the nebulised solution until bronchodilatation is achieved. This usually takes 3–5 minutes.

Some adult patients may require higher doses of salbutamol, up to 10 mg, in which case nebulisation of the undiluted solution may continue until aerosol generation ceases.

Children: The same mode of administration for intermittent administration is also applicable to children. The usual dosage for children under the age of twelve years is 0.5 ml (2.5 mg salbutamol) diluted to 2.0 or 2.5 ml with sterile distilled water or normal saline. Some children may however require higher doses of salbutamol up to 5.0 mg.

Intermittent treatment may be repeated four times daily.

2. *By continuous administration:* Ventolin Respirator Solution is diluted with sterile distilled water or normal saline for injection to contain 50–100 mcg of salbutamol per ml, (1–2 ml solution made up to 100 ml with diluent). The diluted solution is administered as an aerosol by a suitably driven nebuliser. The usual rate of administration is 1–2 mg per hour.

Delivery of the aerosol may be by facemask, 'T' piece or via an endotracheal tube. Intermittent positive pressure ventilation may be used but is rarely necessary. When there is a risk of anoxia through hypoventilation, oxygen should be added to the inspired air.

Contra-indications, warnings, etc

Contra-indications: Nil.

Precautions: Ventolin Respirator Solution should be used with care in patients known to have received large doses of other sympathomimetic drugs.

It should be administered cautiously to patients suffering from thyrotoxicosis.

Ventolin Respirator Solution is to be used with a respirator or nebuliser only, under the direction of a physician. It is not to be injected or administered orally.

Patients receiving treatment at home with Ventolin Respirator Solution must be warned that if either the usual relief is diminished or the usual duration of action reduced, they should not increase the dose or its frequency of administration, but should seek medical advice.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: A small increase in heart rate may occur in patients who inhale large doses of Ventolin. This is not usually accompanied by any changes in the electrocar-

diogram. Other side-effects which may occur with very high doses of Ventolin by inhalation are peripheral vasodilatation and fine tremor of skeletal muscle.

Overdosage: During continuous administration of Ventolin Respirator Solution any signs of overdosage can usually be counteracted by withdrawal of the drug.

The preferred antidote for overdosage with Ventolin Respirator Solution is a cardioselective beta-blocking agent, but β -blocking drugs should be used with caution in patients with a history of bronchospasm.

Pharmaceutical precautions *Storage:* Ventolin Respirator Solution should be stored at a temperature below 25°C and protected from light. Once a bottle has been opened the contents should be discarded after one month.

Dilution: Ventolin Respirator Solution may be diluted with Water for Injections BP or Sodium Chloride Injection BP (normal saline).

Solutions in nebulisers should be replaced daily.

Legal category POM.

Package quantities Ventolin Respirator Solution is supplied in screw-capped bottles of 20 ml.

Further information Ventolin does not cause difficulties in micturition because, unlike sympathomimetic drugs such as ephedrine, it does not stimulate alpha-adrenoceptors. Ventolin is not contra-indicated in patients under treatment with monoamine oxidase inhibitors (MAOIs).

Ventolin Respirator Solution is suitable for treating bronchospasm in patients with co-existing heart disease or hypertension.

Product licence number 0045/5023.

VENTOLIN® ROTACAPS*

Presentation Ventolin Rotacaps, an alternative inhalation form of salbutamol to Ventolin Inhaler, are especially valuable for treating patients who are unable to use pressurised inhalers effectively or who might use them unwisely.

Ventolin Rotacaps contain a mixture of microfine salbutamol sulphate and larger particle lactose in blue/colourless hard gelatine cartridges. Each Rotacap contains 200 mcg (light blue) or 400 mcg (dark blue) of salbutamol (as sulphate) and is marked Ventolin 200 or Ventolin 400. The contents of a Rotacap are inhaled using a specially developed device called a Rotahaler* which separates the cartridge into halves that rotate and release the drug when the patient inhales. This breath actuation is very sensitive and so the drug is fully available even at the lowest inspiratory flow rates. The Rotahaler is, therefore, a more reliable drug delivery system for many patients, but a rather larger unit dose relative to Ventolin Inhaler is necessary for the same therapeutic effect.

Uses Salbutamol BP is a beta-adrenergic stimulant which has a highly selective action on bronchial beta-adrenoceptors and little or no effect on cardiac beta-receptors at therapeutic doses.

Salbutamol is also highly active in preventing antigen-induced release of histamine and slow-reacting substance of anaphylaxis, SRS(A), from mast cells in human lung sensitised with IgE antibody. Such Type I hyper-

sensitivity reactions are generally considered to be the primary triggers of the allergic asthma syndrome.

Ventolin Rotacaps are therefore indicated both for the treatment and prevention of bronchial asthma, and also for the treatment of other conditions, such as bronchitis and emphysema, with associated reversible airway obstruction. Inhaled salbutamol has a long duration of action and Ventolin Rotacaps are ideally suited for routine maintenance therapy and prophylaxis in chronic asthma, both to relieve persistent bronchospasm and to suppress the allergic response within the lungs. Their regular use is also indicated for controlling persistent bronchospasm in chronic bronchitis.

Ventolin Rotacaps act rapidly and may be used when necessary to relieve attacks of acute dyspnoea. Rotacaps may also be used before exertion to prevent exercise-induced asthma or before exposure to a known unavoidable allergen challenge.

The effective dose of salbutamol from Rotacaps is only one tenth of the usual oral dose and so the skeletal muscle tremor sometimes associated with oral therapy does not occur.

The selective action of salbutamol on the bronchi and its lack of effects on the cardiovascular system make Ventolin Rotacaps particularly suitable for treating patients with co-existing heart disease or hypertension, including those taking beta-blocking drugs which often impair respiratory function.

Dosage and administration Ventolin Rotacaps for inhalation use only, using a Ventolin Rotahaler.

Adults: For the relief of acute bronchospasm and for managing intermittent episodes of asthma, 200 mcg or 400 mcg may be administered as a single dose.

The recommended dose for chronic maintenance or prophylactic therapy is 400 mcg three or four times a day.

To prevent exercise-induced bronchospasm, 400 mcg should be taken before exertion.

Children: 200mcg is the recommended dose for the relief of acute bronchospasm, in the management of episodic asthma or before exercise.

200 mcg should be administered three or four times a day for routine maintenance or prophylactic therapy.

For optimum results, in most patients Ventolin Rotacaps should be used regularly.

The bronchodilator effect of these doses of inhaled salbutamol should last for at least four hours, except in patients with relatively severe asthma who require additional treatment with an inhaled and/or systemic glucocorticosteroid.

Contra-indications, warnings, etc

Contra-indications: Although intravenous salbutamol and salbutamol tablets are used in the management of premature labour, Ventolin preparations should not be used for threatened abortion during the first or second trimesters.

Precautions: In the event of a previously effective dose of inhaled Ventolin failing to give relief lasting at least three hours, the patient should be advised to seek medical advice in order that any necessary additional steps may be taken. Ventolin should be administered cautiously to patients suffering from thyrotoxicosis. Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: No important side effects have been reported following treatment with Ventolin Rotacaps.

Overdosage: The preferred antidote for overdosage with salbutamol is a cardioselective beta-blocking agent, but beta-blocking drugs should be used with caution in patients with a history of bronchospasm.

Pharmaceutical precautions To keep the Rotacaps in good condition it is important that they are stored in a dry place where they will not be exposed to extremes of temperature. A convenient supply may be carried in the special container for the Rotahaler. The Rotacaps should only be inserted in the Rotahaler immediately prior to use. Failure to observe this instruction may affect the operation of the Rotahaler.

Legal category POM.

Package quantities Ventolin Rotacaps 200 mcg and 400 mcg are supplied in containers of 100.

Further information Ventolin does not cause difficulty in micturition because, unlike sympathomimetic drugs such as ephedrine, it does not stimulate alpha-adrenoceptors. Ventolin is not contra-indicated in patients under treatment with monoamine oxidase inhibitors (MAOIs).

Ventolin Rotacaps 400 mcg 0045/0117

VENTOLIN* TABLETS VENTOLIN* SYRUP VENTOLIN* SPANDETS*

Presentation *Ventolin Tablets 2 mg:* Pink tablets each containing Salbutamol BP 2 mg as sulphate. Engraved VENTOLIN AH around the perimeter of one side and the number 2 in the centre.

Ventolin Tablets 4 mg: Pink tablets each containing Salbutamol BP 4 mg as sulphate. Engraved VENTOLIN AH around the perimeter of one side and the number 4 in the centre.

Ventolin Syrup: Salbutamol BP 2 mg as sulphate in each 5 ml of a fruit-flavoured, red syrup.

Ventolin Spandets: Salbutamol BP 8 mg as sulphate in a specially designed, two-layered pink and white tablet. Salbutamol is released immediately from the pink layer and gradually from the porous matrix in the white layer. Engraved VENTOLIN SPANDET around the perimeter of one side and AH in the centre.

Uses Salbutamol BP is a beta-adrenergic stimulant which has a highly selective action on the receptors in bronchial muscle and, in therapeutic dosage, little or no action on the cardiac receptors.

Ventolin Tablets 2 mg and 4 mg, Syrup and Spandets are indicated for the relief of bronchospasm in bronchial asthma of all types, chronic bronchitis and emphysema.

Ventolin Syrup is suitable oral therapy for children or for those adults who prefer liquid medicines.

Ventolin Spandets are sustained-action tablets, particularly suitable when nocturnal bronchospasm is a problem.

Because of their selective action on the bronchi and their lack of effects on the cardiovascular system, Ventolin oral preparations are suitable for treating bronchospasm in patients with co-existing heart disease or hypertension.

The selective action of salbutamol on the β_2 -adrenoceptors has led to the use of parenteral Ventolin, usually

as a continuous intravenous infusion, for the management of premature labour during the third trimester of pregnancy. Once the uterine contractions have ceased and the infusion of Ventolin has been gradually withdrawn, maintenance therapy can be effected with Ventolin Tablets.

Dosage and administration *Ventolin Tablets 2 mg and 4 mg and Syrup*: *Adults*: The usual effective dose is 4 mg (one tablet 4 mg or 10 ml of syrup) three or four times per day. If adequate bronchodilatation is not obtained each single dose may be gradually increased to as much as 8 mg.

However, it has been established that some patients obtain adequate relief with 2 mg three or four times daily. In elderly patients or in those known to be unusually sensitive to beta-adrenergic stimulant drugs, it is advisable to initiate treatment with 2 mg three or four times per day.

Children: The following doses should be administered three or four times daily:

2-6 years: 1-2 mg as 2.5-5 ml of syrup or $\frac{1}{2}$ -1 tablet 2 mg.

6-12 years: 2 mg as 5 ml of syrup or 1 tablet 2 mg.

Over 12 years: 2-4 mg as 1 tablet 2 mg or 1 tablet 4 mg.

The drug is well tolerated by children so that, if necessary, these doses can be cautiously increased.

In the management of premature labour, after uterine contractions have been controlled by intravenous infusion of Ventolin and the infusion has been withdrawn, maintenance therapy can be continued with oral Ventolin. The usual dosage is 4 mg three or four times daily.

Ventolin Spandets: *Adults*: 1 Spandet night and morning. In severe cases the dose may be increased to 4 Spandets per 24 hours.

Children over 12 years: 1 Spandet every 12 hours.

Ventolin Spandets must be swallowed whole and not chewed.

Contra-indications, warnings, etc

Contra-indications: Although intravenous salbutamol and salbutamol tablets are used in the management of premature labour Ventolin preparations should not be used for threatened abortion during the first or second trimesters.

Ventolin oral preparations and beta-blocking drugs such as propranolol, should not usually be prescribed together.

Precautions: Ventolin should be administered cautiously to patients suffering from thyrotoxicosis.

Long-term treatment with Ventolin Syrup increases the risk of dental caries and it is essential that adequate dental hygiene is maintained.

Unnecessary administration of drugs during the first trimester of pregnancy is undesirable.

Side-effects: The only side-effect of significance with oral Ventolin is a fine tremor of skeletal muscle which occurs in some patients, usually the hands are most obviously affected. This effect is dose related and is common to all beta-adrenergic stimulants. A few patients feel tense; this is also due to the effects on skeletal muscle and not to direct CNS stimulation. With doses of Ventolin higher than those recommended or in patients who are unusually sensitive to beta-adrenergic stimulants peripheral vasodilatation and a compensatory small increase in heart rate may occur. Occasionally headaches have been reported.

Overdosage: The preferred antidote for overdosage with Ventolin is a cardioselective beta-blocking agent, but beta-blocking drugs should be used with caution in patients with a history of bronchospasm.

Pharmaceutical precautions *Storage*: Ventolin Tablets 2 mg and 4 mg and Ventolin Spandets should be stored at a temperature not exceeding 30°C. Ventolin Syrup should be stored at a temperature below 25°C and protected from light.

Dilution: Ventolin Syrup may be diluted with unpreserved Syrup BP. The resulting mixture should be protected from light and it will keep for 14 days.

Legal category POM.

Package quantities Ventolin Tablets 2 mg are supplied in containers of 100 and 500.

Ventolin Tablets 4 mg are supplied in containers of 100 and 500.

Ventolin Syrup is supplied in bottles of 150 ml and 2 litres.

Ventolin Spandets are supplied in containers of 50.

Further information Ventolin does not cause difficulty in micturition because, unlike sympathomimetic drugs such as ephedrine, it does not stimulate alpha-adrenoceptors. Ventolin is not contra-indicated in patients under treatment with monoamine oxidase inhibitors (MAOIs).

BLEPH* - 10 OPHTHALMIC SOLUTION

Presentation Clear, colourless to slightly straw colour, sterile, ophthalmic solution containing 10.0% sodium sulphacetamide, and 0.005% thimerosal as preservative.

Uses For the treatment of conjunctivitis, corneal ulcer, and other superficial ocular infections from susceptible micro-organisms, and as an adjunct to systemic sulphonamide therapy of trachoma.

Dosage and administration 1 to 2 drops into lower conjunctival sac every two to three hours during the day, less often at night.

Contra-indications, warnings, etc The product should not be used when there is known to be hypersensitivity to sulphonamide preparations. The solution is incompatible with silver preparations. Non-susceptible organisms, including fungi, may proliferate with the use of this preparation. Sulphonamides are inactivated by the aminobenzoic acid present in purulent exudates.

Pharmaceutical precautions Protect from excessive light and heat. Do not use if the solution is discoloured (dark brown).

Legal category POM.

Package quantities Bleph-10 is available in 5 ml and 10 ml plastic dropper bottles.

Further information Nil (sulphonamides exert a bacteriostatic effect against a wide range of gram-positive and gram-negative micro-organisms by restricting, through competition with para-aminobenzoic acid, the synthesis of folic acid which bacteria require for growth).

Product licence number 0426/0003.

EPIFRIN* 1% OPHTHALMIC SOLUTION

Presentation Clear, colourless to very slightly straw coloured, sterile, aqueous ophthalmic solution containing 1.0% Adrenaline, present as the hydrochloride, and 0.004% benzalkonium chloride as preservative.

Uses Chronic simple glaucoma. In many cases control of intraocular pressure can be obtained when miotics have failed, and is most useful in combination with miotics to obtain better control.

Dosage and administration The usual dosage is one drop in affected eye(s) once daily. However the dosage should be adjusted to meet the needs of the individual patient.

Contra-indications, warnings, etc Should not be used in closed-angle glaucoma, since the dilation of the pupil may precipitate an acute attack. Undesirable side reactions may include eye pain or ache, brow ache, headache, conjunctival hyperemia and allergic lid reactions. Adrenochrome deposits in the conjunctiva and cornea after prolonged epinephrine therapy have been reported. Adrenaline has been reported to produce macular oedema in some aphakic patients and should be used with caution in these patients.

Pharmaceutical precautions Protect from excessive light. If the solution discolours or a precipitate forms it should be discarded.

Legal category P.

Package quantities Epifrin 1% is available in a 10 ml plastic dropper bottle.

Further information Nil.

Product licence number 0426/0018.

EPIFRIN* 2% OPHTHALMIC SOLUTION

Presentation Clear, colourless to very slightly yellow, sterile, aqueous ophthalmic solution containing 2.0% Adrenaline, present as the hydrochloride, and 0.004% benzalkonium chloride as preservative.

Uses Chronic simple glaucoma. In many cases control of intraocular pressure can be obtained when miotics have failed, and is most useful in combination with miotics to obtain better control.

Dosage and administration The usual dosage is one drop in affected eye(s) once daily. However the dosage should be adjusted to meet the needs of the individual patient.

Contra-indications, warnings, etc Should not be used in closed-angle glaucoma, since the dilation of the pupil may precipitate an acute attack. Undesirable side reactions may include eye pain or ache, brow ache, headache, conjunctival hyperemia and allergic lid reactions. Adrenochrome deposits in the conjunctiva and cornea after prolonged epinephrine therapy have been reported. Adrenaline has been reported to produce macular oedema in some aphakic patients and should be used with caution in these patients.

Pharmaceutical precautions Protect from excessive light. If the solution discolours or a precipitate forms, it should be discarded.

Legal category P.

Package quantities Epifrin 2% is available in a 10 ml plastic dropper bottle.

Further information Nil.

Product licence number 0426/0008.

FML* STERILE OPHTHALMIC SUSPENSION ▼

Presentation White microfine sterile ophthalmic suspension containing 0.1% fluoromethalone and 0.004% benzalkonium chloride as preservative.

Uses Topical ophthalmic suspension for steroid responsive inflammation of the palpebral and bulbar conjunctiva, cornea and anterior segment of the globe.

Dosage and administration 1 to 2 drops instilled into the conjunctival sac two to four times daily. During the initial 24 to 48 hours the dosage may be safely increased to 2 drops every hour. Care should be taken not to discontinue therapy prematurely.

Contra-indications, warnings, etc

Contra-indications: Acute superficial herpes simplex keratitis. Fungal diseases of ocular structures. Vaccinia, varicella and most other viral diseases of the cornea and conjunctiva. Tuberculosis of the eye. Hypersensitivity to the constituents of this medication.

Warnings: Steroid medication in the treatment of herpes simplex keratitis (involving the stroma) requires great caution: frequent slit-lamp microscopy is mandatory. Prolonged use may result in glaucoma, damage to the optic nerve, defects in visual acuity and fields of vision, posterior subcapsular cataract formation, or may aid in the establishment of secondary ocular infections from fungi or viruses liberated from ocular tissue.

In those diseases causing thinning of the cornea or sclera, perforation has been known to occur with use of topical steroids.

Safety and effectiveness have not been demonstrated in children of the age group two years or below.

This preparation contains benzalkonium chloride and should be used with caution in association with hydrophilic contact lenses.

Use in pregnancy: Safety of the use of topical steroids during pregnancy has not been established.

Precautions: As fungal infections of the cornea are particularly prone to develop coincidentally with long-term local steroid applications, fungus invasion must be suspected in any persistent corneal ulceration where a steroid has been used or is in use.

Intraocular pressure should be checked frequently.

Adverse reactions: Glaucoma with optic nerve damage, visual acuity or field defects, posterior subcapsular cataract formation, secondary ocular infection from pathogens liberated from ocular tissues, perforation of the globe.

Local side-effects of steroid therapy, i.e. skin atrophy, striae and telangiectasia, are especially likely to affect facial skin.

Pharmaceutical precautions Protect from freezing.

Legal category POM.

Package quantities Supplied in plastic dropper bottles of 5 ml and 10 ml.

Further information Nil.

Product licence number 0426/0028.

LACRI-LUBE*

Presentation Sterile, bland, non-medicated ophthalmic ointment, for topical administration to humans, containing white petrolatum mineral oil, non-ionic lanolin derivatives with chlorobutanol 0.5% as a preservative.

Uses Useful as adjunctive therapy to lubricate and protect the eye in conditions characterized by exposure keratitis, decreased corneal sensitivity, recurrent corneal erosions, keratitis sicca, ophthalmic surgeries and non-ophthalmic surgeries.

Dosage and administration For topical administration. Pull lower lid down to form pocket. Apply small amount as needed.

Contra-indications, warnings, etc No known contra-indications.

Pharmaceutical precautions Store away from heat. To avoid contamination during use, do not touch tip to any surface.

Legal category P.

Package quantities Available in 3.5 g ophthalmic ointment tubes.

Further information Nil.

Product licence number 0426/0041.

LIQUIFILM* TEARS

Presentation Clear, colourless to slightly straw coloured, sterile, aqueous ophthalmic solution, containing 1.4% polyvinyl alcohol and 0.5% chlorobutanol as preservative.

Uses For dry eyes, especially where natural mucus is absent, or deficient, also as an ocular lubricant.

Dosage and administration 1 drop in the eye as needed, or as directed.

Contra-indications, warnings, etc Not for use with soft contact lenses. If irritation increases or persists, discontinue use.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Liquifilm Tears is available in plastic dropper bottles containing 15 ml.

Further information Nil.

Product licence number 0426/0009.

PREFRIN* EYE DROPS

Presentation Clear, colourless, sterile, aqueous ophthalmic solution containing 0.12% phenylephrine hydrochloride, and 0.004% benzalkonium chloride as preservative.

Uses For treatment of non-infectious, mild ocular irritations and redness of non specific aetiology.

Dosage and administration 1 or 2 drops in each eye every three or four hours.

Contra-indications, warnings, etc The product should not be used in the presence of narrow-angle glaucoma. If irritation persists or increases the treatment should be discontinued.

Pharmaceutical precautions The product should not be used later than two weeks after opening the container.

Legal category P.

Package quantities Prefrin is available in plastic dropper bottles of 15 ml.

Further information Nil.

Product licence number 0426/0014.

Station Road Didcot Oxfordshire OX11 7NP

INTROPIN®

Presentation Intropin 800 mg/5 ml ampoules; each ml contains 160 mg dopamine hydrochloride and 1% sodium bisulphite. Intropin 200 mg/5 ml ampoules and prefilled syringes; each ml contains 40 mg dopamine hydrochloride and 1% sodium bisulphite. The solutions are clear and practically colourless.

Uses Actions: Intropin exerts its beneficial haemodynamic effects by its action on different receptors; at 1–5 mcg/kg/min Intropin dilates the renal and mesenteric vascular beds by its unique action on 'dopaminergic' receptors, causing increases in glomerular filtration rate, renal blood flow, sodium excretion, and urine output.

At 5–20 mcg/kg/min Intropin exerts a direct inotropic effect on the myocardium causing dose related increases in cardiac output with minimal effect on heart rate. Blood pressure usually rises and further increases in the urine output are seen.

At 20 mcg/kg/min and above there are further increases in cardiac output and Intropin raises blood pressure by its alpha adrenergic action on peripheral blood vessels, however, even at these doses, renal blood flow is higher than prior to therapy.

Preparation: Transfer 800 mg Intropin by aseptic technique to 500 ml of one of the following sterile intravenous solutions:

1. Sodium Chloride Injection
2. 5% Dextrose Injection
3. 5% Dextrose and 0.9% Sodium Chloride Injection
4. 5% Dextrose in 0.45% Sodium Chloride Solution
5. 5% Dextrose in Lactated Ringer Solution
6. Sodium Lactate (1/6 Molar) Injection
7. Lactated Ringer's Injection.

This gives a concentration of 1,600 micrograms/ml of Intropin.

Intropin is stable for a minimum of 24 hours after dilution in the above solutions, however dilution should be made just before administration.

Do NOT add Intropin to 5% sodium bicarbonate or other alkaline solution since the drug is inactivated.

Administration: Intropin, after dilution, is administered intravenously through an intravenous catheter or needle in as large a vein as possible. An I.V. drip chamber or infusion pump is essential for controlling the infusion rate in drops/minute. The infusion rate should be titrated to the optimum patient response and constantly evaluated in terms of patient's changing condition.

Indications: Intropin is indicated for the correction of poor perfusion, low cardiac output, impending renal failure and shock associated with: Myocardial infarction, Trauma, Endotoxic septicaemia, Open heart surgery, Heart failure.

Dosage and administration Warning: This is a potent drug. It must be diluted before administration.

Dosage: Where appropriate, restoration of blood volume with a suitable plasma expander should be started or completed before Intropin therapy. Begin infusion of Intropin therapy at 2 mcg/kg/min in patients who are likely to respond to modest increments in heart force and renal perfusion. In more seriously ill patients begin infusion of Intropin at 5 mcg/kg/min, and in both cases the infusion rate should be titrated upwards in 5–10 mcg/kg/min increments until the optimum dose for the patient is achieved as judged by increases in blood pressure, urine flow, and perfusion generally. Doses of 50 mcg/kg/min and above have been successfully used, although urine output should be checked frequently, and should it fall, dosage reduction of Intropin should be considered.

Contra-indications, warnings, etc

Contra-indications: Intropin should not be used in patients with phaeochromocytoma.

Warnings: Intropin should not be used in the presence of uncorrected tachyarrhythmias or ventricular fibrillation.

Patients who have been treated with monoamine oxidase (MAO) inhibitors prior to Intropin should be given reduced doses; the starting dose should be one tenth ($\frac{1}{10}$) of the usual dose.

Usage in Pregnancy: Animal studies have shown no evidence of teratogenic effects with Intropin. The drug may be used in pregnant women when the expected benefits outweigh the potential risk to the foetus.

Usage in children: The safety and efficacy of Intropin use in children has not been established.

Precautions: Hypovolaemia should be corrected where necessary prior to Intropin infusion. Vasoconstriction can occur due to the alpha adrenergic actions of Intropin, especially in patients with a history of occlusive vascular disease. If desired, this condition can be rapidly reversed by dose reduction or discontinuing the infusion, since Intropin has a half-life of less than 2 minutes in the body. Intropin at the infusion site can cause local vasoconstriction, hence the desirability of infusing into a large vein. The resulting ischaemia can be reversed by infiltration of the affected area with 10–15 ml of saline containing 5 to 10 mg phentolamine mesylate. A syringe with a fine hypodermic needle should be used to liberally infiltrate the ischaemic area as soon as extravasation is noted.

Adverse reactions: Adverse reactions to Intropin are entirely related to its pharmacological action; immune mediated reactions are not seen since dopamine is a normal body product. The most frequently reported reactions to Intropin have been ectopic beats, tachycardia, anginal pain, palpitations, dyspnoea, nausea, vomiting, hypotension and vasoconstriction. Very rarely reported reactions include aberrant conduction, bradycardia, piloerection, widened QRS complex, azotaemia and hypertension. Vomiting is rare with Intropin, but should it occur, electrolyte replacement should be given.

Overdosage: Accidental overdosage as evidenced by excessive blood pressure elevation can be controlled by dose reduction or discontinuing the Intropin infusion for a short period, since the duration of action of Intropin is short.

Should these measures fail, an infusion of phentolamine mesylate should be considered.

Pharmaceutical precautions Do not add Intropin to 5% sodium bicarbonate or other alkaline solution since the drug is inactivated. Protect from light, do not use if discoloured. Avoid contact with solutions of alkalis.

Legal category POM.

Package quantities Ampoules containing 200 mg dopamine hydrochloride, 20 ampoules per outer carton. Ampoules containing 800 mg dopamine hydrochloride 20 ampoules per outer carton. Pre-filled syringes containing 200 mg dopamine hydrochloride, 5 syringes per outer carton.

Further information Nil.

Intropin 200 mg 3295/0001
Intropin 800 mg 3295/0004

TRIDIL*

Presentation Tridil 50 mg is supplied as a sterile, non-pyrogenic, practically colourless solution containing 5 mg/ml nitroglycerin in 30% alcohol and 30% propylene glycol and water for injection. Each 10 ml ampoule contains 50 mg nitroglycerin for intravenous infusion.

Tridil 5 mg is supplied as a sterile, non-pyrogenic solution containing 0.5 mg/ml nitroglycerin stabilized by alcohol BP 10% v/v, lactose and monobasic potassium phosphate. Each 10 ml glass ampoule contains 5 mg nitroglycerin for intravenous use.

Actions: Nitroglycerin causes relaxation of vascular smooth muscle. In a dose related manner nitroglycerin produces dilatation of both the arterial and venous vascular beds, however, the venous effects predominate. Dilatation of the post capillary vessels including large veins results in peripheral pooling and a reduction in venous return. Therapeutic doses of Tridil given intravenously produce a reduction in left ventricular end diastolic volume, left ventricular end diastolic pressure and myocardial wall tension. Myocardial oxygen consumption, as measured by the rate pressure product and tension time index is decreased.

Pulmonary vascular resistance, systemic vascular resistance and arterial pressure are all reduced by Tridil administration. Although the predominant clinical benefits result from the peripheral venodilating effects and the resultant reduction in myocardial oxygen demand, some effect on oxygen supply may occur by direct coronary vasodilatation. A re-distribution of blood from normal to ischaemic areas of the myocardium has been demonstrated.

Uses *Surgery:* Tridil may be used for the prompt control of hypertension encountered during cardiac surgery.

Tridil may be used to reduce blood pressure and maintain controlled hypotension during surgical procedures.

Tridil may be used to control myocardial ischaemia during and after cardiovascular surgery.

Unresponsive Congestive Cardiac Failure Secondary to

Acute Myocardial Infarction: Tridil may be used to reduce elevated left ventricular filling pressure in patients with unresponsive congestive cardiac failure secondary to acute myocardial infarction.

Unstable Angina: Tridil infusion can reduce myocardial oxygen demand in proportion to the reduction in pre-load and after-load. Tridil may be indicated for the control of anginal episodes in patients with unstable angina who are refractory to treatment with standard therapy.

Patients with recurrent myocardial ischaemia not responsive to beta-blockers or sublingual nitrates may benefit from the intravenous Tridil infusion prior to surgery or angiography.

Frequent monitoring of blood pressure and pulse rate are recommended during the infusion.

Dosage and administration Tridil is a concentrated pharmacological drug which should be diluted in 5% Dextrose in Water or 0.9% Sodium Chloride prior to its infusion.

It is recommended that the drug is diluted to give a final concentration of 400 mcg/ml or less according to the dosage requirements of the patient. Most patients respond to doses between 10–200 mcg/min, although doses up to 400 mcg/min may be required during some surgical procedures.

Compatibility: (See also Pharmaceutical Precautions) Tridil is compatible with glass infusion bottles. Tridil has also been shown to be compatible with certain rigid infusion packs made of polyethylene; these include the Boots polyfusor and the bottlepack distributed by Dylade, Cheshire U.K. (bottlepack; flatpak) or Antigen Ltd., Roscrea, S. Ireland (Braun). Tridil can be administered as an infusion using one of these recommended infusion bottles/packs.

Tridil is not compatible with infusion bags made from PVC and loss of activity in excess of 40% may occur if contact between nitroglycerin and polyvinylchloride is prolonged. It is therefore recommended that contact with PVC bags is avoided. Some loss of activity can also occur through the infusion sets but the clinical response should be used to determine the rate of infusion and thus the dosage of the drug required by the patient.

An alternative method of administration is via a syringe pump. Tridil can be infused slowly via a syringe pump using a glass syringe or rigid plastic syringe (Gillette Sabre syringe, Brunswick Disposable, B.D. plastipak syringes). A high pressure polyethylene tubing known to be compatible with nitroglycerin is the Lectrocath tubing, Vygon Gloucester.

The chosen method of administration should ensure that the drug is given at a constant infusion rate.

Dosage: The recommended dosage range is 10–200 mcg/min. Doses in excess of these have been used and up to 400 mcg/min may be required during some surgical procedures.

Clinical assessment and frequent monitoring of blood pressure are essential to maintain the appropriate infusion rate. Where available, measurement of pulmonary capillary wedge pressure and cardiac output can be used to titrate dosage to response.

Surgery: For the control of hypertensive episodes the recommended starting dose is 25 mcg/min increasing in steps of 25 mcg/min at 5 minute intervals until the desired drop in B.P. is achieved. Although most patients respond to doses between 10–200 mcg/min, doses up to 400 mcg/min have been required during some surgical

procedures. In the treatment of perioperative myocardial ischaemia, the recommended starting dose is 15–20 mcg/min increasing in steps of 10–15 mcg/min until the desired effect is achieved.

Unresponsive Congestive Cardiac Failure Secondary to Acute Myocardial Infarction: The recommended starting dose is 20–25 mcg/min which can be decreased to 10 mcg/min or increased in steps of 20–25 mcg/min at 15–30 minute intervals until the desired effect is achieved.

Unstable angina: The recommended starting dose is 10 mcg/min increasing in steps of 5–10 mcg/min at approximately 30 minute intervals.

Children: The safety and efficacy of Tridil has not been established in children.

Contra-indications, warnings, etc Tridil should not be given to patients with known hypersensitivity to nitrates.

Tridil should not be used in patients with marked anaemia, severe cerebral haemorrhage, uncorrected hypovolaemia or severe hypotension.

Tridil should be used with caution in patients suffering from hypothyroidism, malnutrition, severe liver or renal disease or hypothermia.

As with all vasodilators, Tridil should be used with caution in patients predisposed to closed angle glaucoma.

As the safety of Tridil during pregnancy and lactation has not been established, it should not be used unless considered essential by the physician.

Adverse reactions to nitrates may include hypotension, tachycardia, nausea, retching, diaphoresis, apprehension, headache, restlessness, muscle twitching, retrosternal discomfort, palpitations, dizziness, and abdominal pain. Paradoxical bradycardia has occasionally been observed.

Mild overdosage usually resulting in hypotension and tachycardia can be reversed by elevating the legs or decreasing or terminating the infusion. If severe, intravenous administration of methoxamine or phenylephrine is recommended.

Pharmaceutical precautions Opened ampoules should be used immediately and any unused diluted drug should be discarded.

Tridil solution is stable for at least 24 hours at room temperature in glass or recommended plastic containers (see compatibility). Considerable losses of nitroglycerin will occur if Tridil is in contact with polyvinylchloride (PVC) plastic infusion bags and therefore contact with PVC should be avoided. Tridil should therefore be administered in the recommended infusion bottles/packs or via a syringe pump.

Protect from strong light. Do not use if discoloured.

Legal category POM.

Package quantities Tridil 50 mg is available as either a Tridilkit (incorporating one 10 ml ampoule and a compatible infusion set—Tridilset) or in a box containing four 10 ml ampoules.

Tridil 5 mg is available in a box containing five 10 ml ampoules.

Further information Experience so far has shown that when given by slow infusion, the onset of action occurs within approximately 3–5 minutes.

Nitroglycerin is also known as glyceryl trinitrate, trinitroglycerin and trinitrin.

APSIFEN® **APSIFEN®-F**

Presentation Apsifen is available in two presentations:
Apsifen: Plain round biconvex pink sugar-coated tablets.
Apsifen-F: Round biconvex pink film-coated tablets marked 'APS' on one side and plain on the other side.

Both presentations contain the same active ingredient, Ibuprofen BP, and both are available in two strengths, 200 mg and 400 mg. They comply with the monograph for Ibuprofen Tablets BP.

Uses Ibuprofen is a non-steroidal anti-inflammatory agent with analgesic and anti-pyretic activity. Its principal effects are to relieve pain and stiffness and to reduce swelling.

Apsifen and Apsifen-F may therefore be used in the management of:

- (a) Rheumatoid Arthritis including Still's disease;
- (b) Osteoarthritis and seronegative (non rheumatoid) arthropathies;
- (c) Ankylosing Spondylitis.

Like other similar agents, Ibuprofen has also been used in non-articular rheumatic conditions and in soft-tissue injuries.

Dosage and administration (Oral)

Adults: Initially 1200 mg per day in divided doses. In severe conditions up to 1600 mg per day may be given until the acute phase of the condition has been brought under control. Some patients may be maintained on doses in the range 600–1200 mg per day.

Children: 20 mg/kg of body weight given daily in divided doses. The tablets are not suitable for children weighing less than 20 kg and no more than two 200 mg tablets should be given in 24 hours to those weighing less than 30 kg.

Contra-indications, warnings, etc

Contra-indications: Ibuprofen should not be used in patients with:

- (a) active peptic ulceration;
- (b) a history of severe peptic ulceration.

Precautions: Special care must be taken when using Ibuprofen in the following situations:

- (a) In patients with asthma;
- (b) In allergic patients or in patients who have developed bronchospasm with other non-steroidal anti-inflammatory agents;
- (c) Pregnancy: As with other agents the use of Ibuprofen during pregnancy should be avoided if possible.

Adverse reactions: As with other non-steroidal anti-inflammatory agents, the most common unwanted effects with Ibuprofen include dyspepsia, gastro-intestinal intolerance and bleeding. Other unwanted effects include a variety of skin rashes and, less commonly, thrombocytopenia. A few cases of toxic amblyopia which recovered on withdrawal of treatment have been reported.

Overdosage: There is no specific antidote to Ibuprofen. Management usually includes gastric lavage associated with special care of plasma electrolytes and any other appropriate symptomatic relief.

Pharmaceutical precautions Apsifen and Apsifen-F Tablets should be stored at room temperature in a dry place and protected from light.

Legal category POM.

Package quantities Polypropylene tubes of 100 and 500 tablets.

Further information Nil.

Product licence numbers

Apsifen and Apsifen-F Tablets 200 mg 0289/0029

Apsifen and Apsifen-F Tablets 400 mg 0289/0037

APSIN® VK

Presentation Apsin VK is available in two presentations, tablets and granules for syrup.

Apsin VK Tablets are round, white, biconvex tablets, scored on one surface, available in two strengths containing the equivalent of 125 mg and 250 mg Penicillin V (as the potassium salt). The products comply with the specification for Phenoxymethylpenicillin Tablets BP.

Apsin VK Syrups are prepared by adding water to the granules to produce an orange coloured and flavoured clear syrup. Each 5 ml syrup contains the equivalent of 125 mg or 250 mg Penicillin V (as the potassium salt). The products comply with the specification for Penicillin V Elixir BPC.

Uses Phenoxymethylpenicillin is a bactericidal agent active against penicillin-sensitive Gram-positive bacteria.

Apsin VK may therefore be used in the management of infections due to penicillin-sensitive organisms, in particular streptococci and staphylococci.

As with other similar agents Phenoxymethylpenicillin has occasionally been used prophylactically, when appropriate before and after surgery or dental treatment in patients at risk from bacterial endocarditis owing to congenital or acquired cardiac valvular disease – eg. rheumatic heart disease.

Dosage and administration (Oral).

Adults: 250 mg every 4 hours, or for prophylaxis 125 mg every 12 hours.

Children: aged 6 to 12 years, 250 mg every six hours; aged 1 to 5 years, 125 mg every six hours.

Infants: under 12 months old should receive 62.5 mg every six hours.

It is recommended that doses are taken 30 minutes before food.

In patients with beta-haemolytic streptococcal infection, it is usual to continue treatment at the full dosage for 10 days in order to minimise the occurrence of secondary complications such as acute nephritis and rheumatic fever.

Contra-indications, warnings, etc

Contra-indications: Phenoxymethylpenicillin should not be used in patients with:

- (a) chronic or deep-seated infections such as subacute bacterial endocarditis, meningitis or syphilis.
- (b) hypersensitivity to penicillins.

Precautions: Special care must be taken when using Phenoxymethylpenicillin in patients with a history of allergy, as they are more likely to develop hypersensitivity reactions. For this reason, penicillin should not be used for trivial infections.

Adverse reactions: Occasionally patients suffer from transient diarrhoea. Hypersensitivity reactions such as urticaria are less common and usually milder than those associated with penicillins given by injection. However, as with all penicillins, anaphylaxis can occur in susceptible hypersensitive individuals and is an acute emergency. Normally, sensitivity reactions may be controlled with antihistamines or, if these fail, with systemic corticosteroids or pressor amines such as adrenaline.

Overdosage: There are no serious sequelae reported, and management should be symptomatic.

Pharmaceutical precautions

Storage: Apstin VK Tablets and granules for Syrup should be stored below 20°C in a dry place, not in a refrigerator. The tablets should be dispensed in airtight containers.

Apstin VK Syrups, when reconstituted, should be used within seven days. They will retain potency for this period if stored below 15°C.

Dilution: Apstin VK Syrups can be diluted with Syrup BP if required. Such dilutions must be freshly prepared.

Legal category POM.

Package quantities

Apstin VK Tablets: Polypropylene tubes of 500 and 1000.

Apstin VK Syrups: Granules to produce 100 ml of Syrup when reconstituted with 60 ml water for 250 mg/5 ml Syrup or 65 ml water for 125 mg/5 ml Syrup.

Further information Nil.

APSOLOL*

Presentation Apsolol is presented as pink, round, biconvex, film-coated tablets scored on one side and marked 'APS' on the other side. The tablets are also marked with the strength and code number on the scored side. They contain Propranolol Hydrochloride BP and comply with the monograph for Propranolol Tablets BP. Four strengths are available:

Apsolol 10 mg (of Propranolol Hydrochloride BP) marked '10/0212'
Apsolol 40 mg (of Propranolol Hydrochloride BP) marked '40/0213'

Apsolol 80 mg (of Propranolol Hydrochloride BP) marked '80/0214'

Apsolol 160 mg (of Propranolol Hydrochloride BP) marked '160/0215'

Uses Propranolol is a beta adrenergic receptor blocking agent. Its principal effects are on the cardiovascular system.

Apsolol may therefore be used in the management of:

- (a) Angina Pectoris;
- (b) Hypertension;
- (c) Some forms of Cardiac Dysrhythmias;
- (d) Anxiety and Anxiety-induced Tachycardia;
- (e) Hypertrophic Obstructive Cardiomyopathy;
- (f) Essential Tremor.

Beta adrenergic blocking agents, including propranolol, are also used in the prophylaxis of migraine and as an adjunct to the management of Thyrotoxicosis and Cardiac Dysrhythmias associated with anaesthesia.

Dosage and administration (Oral)

Adults: Angina Pectoris, Anxiety, Migraine and Essential Tremor: Initially 40 mg two to three times per day increased at weekly intervals to suit the patient's requirements. The usual dose for angina is in the range 120–240 mg per day and for anxiety, migraine and essential tremor in the range 80–160 mg per day.

Adults: Hypertension: The usual initial dose is 80 mg twice daily and may be increased at weekly intervals as necessary. Most patients will be managed with a dose in the range 160–320 mg per day. It is usual to add a suitable diuretic to the management of most hypertensives who require the higher doses of a beta-blocker.

Adults: Dysrhythmias, Anxiety-induced Tachycardia, Hypertrophic Obstructive Cardiomyopathy and Thyrotoxicosis: Initially 10–40 mg three to four times per day. This dose may be increased to achieve the desired effect.

Children: Occasionally beta-blockers have been given to children for the management of dysrhythmias. There is no accepted dosage scheme, but a useful guide is 0.25–0.50 mg/kg body weight three to four times per day.

Contra-indications, warnings, etc

Contra-indications: Propranolol should not be used:

- (a) In patients with 2nd or 3rd degree heart-block.
- (b) In patients with a history of bronchospasm (Asthma).
- (c) In patients with marked bradycardia (less than 55 b/minute).
- (d) In patients with cardiogenic shock or uncontrolled heart failure.
- (e) In patients receiving VERAPAMIL or other calcium antagonists. Several days should be allowed for complete elimination of one agent before administering the other.

Precautions: Special care must be taken when using beta-blockers such as propranolol in the following situations:

- (a) **Cardiac failure:** If there is evidence of cardiac failure this must be controlled before initiating and during treatment with propranolol.
- (b) **Pulse Rate:** If the pulse rate falls below 50 b/min, treatment should be withdrawn temporarily and resumed at a lower dose.
- (c) **Metabolic Disorders:** In patients with metabolic disorders including alcoholism and diabetic acidosis, great care should be taken in the administration.

tion of propranolol. Treatment with beta-blockers is liable to mask symptoms and deepen the underlying abnormality in hypoglycaemia and other disorders of carbohydrate metabolism. In patients with labile or insulin-dependent diabetes in whom it is proposed to initiate beta-blocker treatment, it may prove necessary to adjust the dosage of the antidiabetic therapy.

- (d) **High Doses:** When high doses of a beta-blocker such as propranolol are used, excessive reduction in blood pressure or pulse rate may occur, particularly when used in conjunction with other hypotensive agents such as neurone blocking agents, vasodilators, reserpine or diuretics.
- (e) **Pregnancy:** Many beta-blockers such as propranolol have been known to cause bradycardia in the foetus, and this may persist after birth. As with all treatment during pregnancy, labour and lactation, extra care should be taken, and as far as possible treatment should be avoided during these periods, to protect the foetus or the suckling new-born child.
- (f) **Other Anti-arrhythmic agents:** Care should be exercised during co-administration or sequential administration, because serious interactions have been reported between some beta-blocking agents and other anti-arrhythmics/cardiac depressants besides verapamil.
- (g) **Anaesthesia:** Should treatment with propranolol be continued over the period of anaesthesia, then atropine (1–2 mg intravenously) should be included in the pre-medication and special care taken to avoid anaesthetics with negative inotropic activity or that encourage vagal dominance, such as ether, cyclopropane, halothane and trichloroethylene. Otherwise withdrawal should be gradual and completed 24 hours before anaesthesia.
- (h) **Renal Failure:** An increased interval between doses may be required to avoid accumulation of propranolol.

Adverse Reactions: Like other beta-blockers, propranolol is well tolerated in normal use. In general untoward effects are minor and include dizziness, headache, insomnia, drowsiness, excitability, gastrointestinal disturbances and rarely bradycardia. Like other beta-blockers, propranolol may precipitate bronchospasm, heart failure, or be associated with cold extremities, and occasionally paraesthesia of the hands, skin rashes and/or dry eyes. The occurrence of these latter symptoms is a reason for discontinuing treatment. (See next paragraph about stopping treatment).

Cessation of treatment: Withdrawal should be gradual, as several beta-blockers, including propranolol, have been associated with a significant increase in symptoms of angina or increase in blood pressure following abrupt withdrawal. If clonidine is co-prescribed, then clonidine should not be withdrawn until several days after Apsolol withdrawal has been completed. (Please refer to prescribing information on clonidine for further information).

Overdosage: Excessive bradycardia and hypotension may be treated with atropine 1–2 mg intravenously and, if necessary, this may be followed by a beta-receptor stimulant such as isoprenaline hydrochloride 25 micrograms intravenously. Where cardiogenic shock has supervened, glucagon 5–10 mg intravenously has been reported to be useful. Bronchospasm may be countered by appropriate beta₂ receptor stimulants such as salbutamol, either by inhalation or 4 micrograms/kg body weight by slow intravenous injection.

Pharmaceutical precautions Apsolol Tablets should be stored at room temperature in a dry place and protected from light.

Legal category POM.

Package quantities

Dispensary packs:

Apsolol 10, 40 and 80 mg: polypropylene tubes of 500 tablets
Apsolol 160 mg: polypropylene tubes of 100 tablets

Patient packs:

Apsolol 10 and 40 mg: white high density polythene bottles of 100 tablets with child resistant screw cap closures.
Apsolol 80 and 160 mg: white high density polythene bottles of 60 tablets with child resistant screw cap closures.

Further information Hypertension is a condition which can benefit from the use of both a beta-blocking agent as contained in Apsolol and a thiazide diuretic such as bendrofluazide. This is because their separate pharmacological actions are complementary in hypertension and may allow adequate treatment with smaller doses of each than would be required if either were to be used alone.

The time-to-peak plasma level in fasted healthy young human volunteers following a single dose of Apsolol is approximately 2 hours, and the excretion half-life of propranolol in plasma is about 2½ hours. However, as with most other beta-blocking agents the onset of biological activity is delayed and the duration is prolonged relative to the plasma concentration. The decay half-life of the biological effect following a single-dose in normal volunteers has been reported to be 11 hours for propranolol, the measure of 'effect' being the reduction in exercise-induced double product (maximum heart rate × systolic blood pressure).†

APSOLOX®

Presentation Apsolex is presented as round, biconvex, film-coated tablets marked 'APS' on one side, while the strength and code number are marked on the other side. The tablets contain Oxprenolol Hydrochloride BP and comply with the monograph for Oxprenolol Tablets BP. Four strengths are available:

Apsolex 20 mg (of Oxprenolol Hydrochloride BP) marked '20/0220' and coloured white.
Apsolex 40 mg (of Oxprenolol Hydrochloride BP) marked '40/0221' and coloured white.
Apsolex 80 mg (of Oxprenolol Hydrochloride BP) marked '80/0222' and coloured yellow.
Apsolex 160 mg (of Oxprenolol Hydrochloride BP) marked '160/0223' and coloured orange.

Uses Oxprenolol is a beta adrenergic receptor blocking agent. As with propranolol its principal effects are on the cardiovascular system. However, oxprenolol is dissimilar

in having partial agonist activity (sometimes termed intrinsic sympathomimetic activity).

Apsolox may therefore be used in the management of:

- (a) Angina Pectoris
- (b) Hypertension
- (c) Some forms of Cardiac Dysrhythmias
- (d) Anxiety-induced Tachycardia
- (e) Hypertrophic Obstructive Cardiomyopathy

Beta adrenergic blocking agents, including oxprenolol, are also used as an adjunct to the management of Thyrotoxicosis and Cardiac Dysrhythmias associated with anaesthesia.

Dosage and administration (Oral)

Adults: Angina Pectoris: The usual dose range is 120–480 mg per day in divided doses to suit the patient's requirements.

Adults: Hypertension: The usual initial dose is 80 mg twice daily and may be increased at weekly intervals as necessary. Most patients will be managed with a dose in the range 160–320 mg per day. It is usual to add a suitable diuretic to the management of most hypertensives who require the higher doses of a beta-blocker.

Adults: Dysrhythmias, Anxiety-induced Tachycardia, Hypertrophic Obstructive Cardiomyopathy and Thyrotoxicosis: Initially 20–40 mg three times per day. This dose may be increased up to 480 mg per day (in divided doses) to achieve the desired effect.

Children: Occasionally beta-blockers have been given to children for the management of dysrhythmias. There is no accepted dosage scheme, but it has been found useful to start with a dose based on 1 mg/kg body weight per day.

Contra-indications, warnings, etc

Contra-indications: Oxprenolol should not be used:

- (a) In patients with 2nd or 3rd degree heart-block.
- (b) In patients with a history of bronchospasm (Asthma).
- (c) In patients with marked bradycardia (less than 55 b/minute).
- (d) In patients with cardiogenic shock or uncontrolled heart failure.
- (e) In patients receiving verapamil or other calcium antagonists. Several days should be allowed for complete elimination of one agent before administering the other.

Precautions: Special care must be taken when using beta-blockers such as oxprenolol in the following situations:

- (a) **Cardiac failure:** If there is evidence of cardiac failure this must be controlled before initiating and during treatment with oxprenolol.
- (b) **Pulse Rate:** If the pulse rate falls below 50 b/min, treatment should be withdrawn temporarily and resumed at a lower dose.
- (c) **Metabolic Disorders:** In patients with metabolic disorders including alcoholism and diabetic acidosis, great care should be taken in the administration of oxprenolol. Treatment with beta-blockers is liable to mask symptoms and deepen the underlying abnormality in hypoglycaemia and other disorders of carbohydrate metabolism. In patients with labile or insulin-dependent diabetes in whom it is proposed to initiate beta-blocker treatment, it may prove necessary to adjust the dosage of the antidiabetic therapy.

(d) **High Doses:** When high doses of a beta-blocker such as oxprenolol are used, excessive reduction in blood pressure or pulse rate may occur, particularly when used in conjunction with other hypotensive agents such as neurone blocking agents, vasodilators, reserpine or diuretics.

(e) **Pregnancy:** Many beta-blockers such as oxprenolol have been known to cause bradycardia in the foetus, and this may persist after birth. As with all treatment during pregnancy, labour and lactation, extra care should be taken, and as far as possible treatment should be avoided during these periods, to protect the foetus or the suckling new-born child.

(f) **Other Anti-arrhythmic agents:** Care should be exercised during co-administration or sequential administration, because serious interactions have been reported between some beta-blocking agents and other antiarrhythmics/cardiac depressants besides verapamil.

(g) **Anaesthesia:** Should treatment with oxprenolol be continued over the period of anaesthesia, then atropine (1–2 mg intravenously) should be included in the pre-medication and special care taken to avoid anaesthetics with negative inotropic activity or that encourage vagal dominance, such as ether, cyclopropane, halothane and trichloroethylene. Similarly, some muscle relaxants – for example suxamethonium – may also increase bradycardia. Otherwise withdrawal should be gradual and completed 24 hours before anaesthesia.

(h) **Renal Failure:** An increased interval between doses may be required to avoid accumulation of oxprenolol.

Adverse Reactions: Like other beta-blockers, oxprenolol is well tolerated in normal use. In general untoward effects are minor and include dizziness, headache, insomnia, drowsiness, excitability, gastrointestinal disturbances and rarely bradycardia. Like other beta-blockers, oxprenolol may precipitate bronchospasm, heart failure, or be associated with cold extremities, skin rashes and/or dry eyes. The occurrence of any of these latter symptoms is a reason for discontinuing treatment. (See next paragraph about stopping treatment).

Cessation of treatment: Withdrawal should be gradual, as several beta-blockers, including oxprenolol, have been associated with a significant increase in symptoms of angina or increase in blood pressure following abrupt withdrawal. If clonidine is co-prescribed, then clonidine should not be withdrawn until several days after Apsolox withdrawal has been completed. (Please refer to prescribing information on clonidine for further information).

Overdosage: Excessive bradycardia and hypotension may be treated with atropine 1–2 mg intravenously and, if necessary, this may be followed by a beta receptor stimulant such as isoprenaline hydrochloride 25 micrograms intravenously. Where cardiogenic shock has supervened, glucagon 5–10 mg intravenously has been reported to be useful. Bronchospasm may be countered by appropriate beta₂ receptor stimulants such as salbutamol, either by inhalation or 4 micrograms/kg body weight by slow intravenous injection.

Pharmaceutical precautions Apsolox Tablets should be stored at room temperature in a dry place. The 80 mg and 160 mg strengths should be protected from light.

Legal category POM.

AAA* MOUTH AND THROAT SPRAY

Presentation The can contains 7.5 g with a valve providing 60 × 100 mg metered doses.

Each metered dose contains:

Benzocaine PhEur 1.5 mg
Cetalkonium Chloride 0.0413 mg.
in an inert flavoured propellant.

Uses Treatment of sore throats caused by cold, post-nasal drip and other irritants, and minor infections of the mouth and throat.

Dosage and administration Shake can before use.

Adults: 2 shots every two to three hours if required (not more than 16 shots in 24 hours or as directed by the physician).

Children aged 6–12: 1 shot every two to three hours if required (not more than 8 shots in 24 hours or as directed by the physician).

Contra-indications, warnings, etc

Side-effects: Hypersensitivity reactions to benzocaine have been reported.

Precautions: Avoid spraying into eyes.

Contents under pressure – do not puncture.

Keep away from heat and flames – do not throw finished container into fire.

Contra-indications: Known hypersensitivity to Benzocaine.

Pharmaceutical precautions Store in a cool place. Shelf-life 5 years. Shake can before use.

Legal category P.

Package quantities Single can containing 7.5 g with a valve providing 60 × 100 mg metered doses (shots).

Further information Published clinical studies have demonstrated antibacterial activity by the reduction in the population of pathogenic organisms of the buccal mucosa. Together with the spray's local anaesthetic activity, this has been found of value in the treatment of pain and infection following tonsillectomy.

Product licence number 0231/5026.

ACTHAR* GEL

Presentation Corticotrophin Gelatin Injection BP in vials containing 20, 40 and 80 i.u./ml for subcutaneous or intramuscular use only.

Uses Rheumatic and Collagen diseases. Asthma. Diseases of the GI tract (e.g. ulcerative colitis). Nephrotic syndrome. Diseases of the CNS (e.g. Bell's Palsy, Retrobulbar Neuritis and Multiple Sclerosis). Adrenal function tests. Chronic skin and allergic conditions responsive to corticosteroids (e.g. psoriasis and certain eczemas and refractory hay fever unresponsive to conventional treatment).

Dosage and administration General information on dosage for therapeutic use. The aim of treatment with Acthar Gel is to obtain a satisfactory therapeutic effect with minimal dosage, the clinical response being the sole measure of adequate dosage. Therapeutic effects may appear within hours, although with some chronic diseases improvement may not show for several days.

Because patients' adrenal glands vary in their sensitivity to ACTH and because disease conditions vary in their response to corticosteroids, no specific uniform dose can be equally effective for all individuals. Some conditions, e.g. acute exacerbations of asthma and multiple sclerosis may require high doses initially to obtain a remission. Once the disease is under control the total daily dosage should be decreased as rapidly as possible. Dosage reduction should be consistent with maintaining clinical improvement. Some conditions, e.g. rheumatoid arthritis, nephrotic syndrome and chronic asthma may need long-term maintenance therapy. Again, the aim is to obtain satisfactory therapeutic effect with minimal dosage. If the treatment regimen is started on a daily basis when the smallest daily maintenance dose has been established (say 20 i.u.), attempts should be made to lengthen the dosage intervals. If at any step of dosage reduction symptoms reappear, a return to the previous effective schedule is necessary before a further attempt at dosage reduction is made. On occasions Acthar Gel can be completely withdrawn as the patient experiences a remission.

Instead of starting with daily injections, it may be more convenient to commence with an initial higher fixed unit dosage (say 40 i.u. per injection) twice or thrice weekly.

Suggested practical regimens for specific conditions are given below. These are guidelines only, the dosage should be titrated to the patient's response.

Conditions needing maintenance therapy

Rheumatoid arthritis: Initially a dose of 40 i.u. should be given daily. Review the dosage at intervals of three days and adjust according to the clinical response. The dosage should be increased or decreased bearing in mind that the ideal dosage is the minimum necessary to relieve symptoms.

Chronic asthma: Initially a dose of 40–80 i.u. should be given daily for a period of five days. Reduce by steps of 10 i.u. until symptoms are satisfactorily controlled. On remission of symptoms, treatment may be withdrawn completely. In some patients, however, continued therapy may be necessary.

Still's disease: 40 i.u. Acthar Gel daily for three days reducing to 20 i.u. on alternate days. Suppression of symptomatology without the appearance of 'cushingoid signs' is the aim of therapy.

The administration of ACTH to children should be confined to early morning (approximately 10 a.m.) to reduce the incidence of 'growth interference'.

Conditions requiring short – medium term therapy *Acute exacerbation of asthma:* 200 i.u. Acthar

Gel repeated at a 72-hour interval gives remission in the majority of cases. Upon remission the dosage should be reduced to maintenance levels (see chronic asthma).

Very high levels of corticosteroids may be needed rapidly in cases of status asthmaticus, and the delay in achieving this by corticotrophin treatment may render this form of therapy inappropriate here, at least initially.

Hay fever: Acthar Gel should be reserved for patients with refractory hay fever unresponsive to conventional treatment, e.g. antihistamines and topical medication, who may benefit from treatment with ACTH Gel. The dosage and duration of treatment will depend upon the severity of the condition. In adults, dosages of up to 40–80 i.u. once or twice weekly during the pollen season can be given. In children under the age of seven, the use of ACTH treatment for hay fever is not recommended unless absolutely necessary. In children over the age of seven, the dosage should not exceed 40–80 i.u. Acthar Gel given in the early morning once or twice weekly during the pollen season. The child should be carefully monitored during the course of therapy for side-effects including diminution of growth velocity and hypothalamic pituitary suppression.

Bell's Palsy: Treatment should commence as soon as possible after the onset of paralysis.

Acthar Gel 80 i.u. daily for five days, reducing to 60 i.u. on day 6, 40 i.u. on day 7, 20 i.u. on day 8 and 10 i.u. on days 9 and 10.

Alternatively a simplified regimen of 40 i.u. daily for 10 days, or until signs of improvement occur, can be employed.

Retrobulbar neuritis: Acthar Gel 40 i.u. daily for a period of 30 days.

Ulcerative colitis and Crohn's disease: For the treatment of acute exacerbations of Crohn's disease and Ulcerative Colitis, a short course of treatment is generally used. The starting dose should be 80–120 units daily and should be rapidly reduced consistent with maintaining clinical remission. Maintenance therapy with other agents may then be necessary.

Multiple Sclerosis: For the treatment of exacerbations of Multiple Sclerosis a diminishing dosage regimen is generally used. The initial dosage should be between 80–120 i.u. daily for the first week. Subsequently daily dosages should be reduced on a weekly basis over three-six weeks to 10–20 i.u. and then stopped.

Nephrotic Syndrome: For the treatment of nephrotic syndrome, a short course of treatment is generally used. Administer Acthar Gel 60–80 i.u. daily for 10–12 days and then stop treatment abruptly to allow spontaneous diuresis. If diuresis is inadequate repeat treatment after 5 days.

Adrenal function tests: Withdraw 5–8 ml venous blood into a heparinised tube, then inject intramuscularly 40 i.u. Acthar Gel. A further sample should be taken after approximately 4 hours and the rise in plasma hydroxy-corticosteroids measured.

Contra-indications, warnings, etc

Precautions and contra-indications: The contra-indications to ACTH are those of corticosteroids but are rarely absolute. Only after careful consideration should ACTH be given to patients suffering from: active tuberculosis, peptic ulcer, acute psychosis, hypertension, diabetes mellitus, congestive heart failure. Cushing's syndrome, osteoporosis or pregnancy.

As with corticosteroids, ACTH may increase susceptibility to infections.

Side-effects: Side-effects such as hyperglycaemia, psychological disturbances, hypertension, sodium retention, potassium loss, peptic ulcer formation and osteoporosis may occur. The occurrence of these side effects may be a sign of overdosage and may be reversed either by reducing the dosage or withdrawing therapy. Some side-effects, such as peptic ulceration and osteoporosis are thought to be less common with ACTH than with corticosteroid therapy.

Warnings: Hypersensitivity reactions may occur.

Pharmaceutical precautions *Acthar Gel:* Should be stored between 2–10°C and protected from light. Shelf-life 18 months.

Legal category POM.

Package quantities For intramuscular and subcutaneous use.

Acthar Gel:

5 ml vial 20 i.u. per ml

2 ml vial 40 i.u. per ml

5 ml vial 40 i.u. per ml

5 ml vial 80 i.u. per ml

Further information

To replace corticosteroids with Acthar Gel:

1. To establish adrenal responsiveness: Administer 80–120 i.u. daily together with current steroid dosage until therapeutic or biochemical response or overdosage effects occur.

Clinical: Increased weight, sense of well-being and increased appetite, flushing of the face, and major reduction of disease symptoms.

Biochemical: Raised plasma cortisol levels or raised urinary excretion of 17-hydroxycorticosteroids.

2. As soon as adrenal response is established, reduce steroids by 25% of the original dose each day, maintaining the above dosage pattern of Acthar Gel.

3. When steroids are safely withdrawn, reduce Acthar Gel dosage to maintenance level.

To replace tetracosactrin depot with Acthar Gel: Substitute 40 units of Acthar Gel for each 0.5 mg of the tetracosactrin depot preparation. There should be no necessity to increase the frequency of injections.

Unduly large or small injection volumes are obviated by the comprehensive range of Acthar Gel strengths which are available.

Acthar Gel 0231/5000, 0231/5051, 0231/5052

ALBUMINAR[®]-5

Presentation Albuminar-5 is a sterile aqueous solution of Normal Serum Albumin (Human) 5% obtained from large pools of adult human venous plasma. Each 100 ml of Albuminar-5 contains 5 g of human serum albumin which is osmotically equivalent to normal human plasma.

The product conforms to the monograph for Normal Serum Albumin (Human) USP.

Indications Albuminar-5 is indicated in: The emergency treatment of shock and in other conditions where the restoration of blood volume is urgent.

Serious burns to prevent haemoconcentration and to combat fluid and sodium losses.

Clinical situations associated with low plasma protein (Hypoproteinaemia) with or without oedema, provided that sodium restriction is not imperative.

Therapeutic Plasma Exchange as a replacement fluid for phoresed plasma.

Dosage and administration (a) *Administration:* Albuminar-5 is for intravenous infusion.

Albuminar-5 may be given intravenously without further dilution; 5% solution is approximately isotonic and isosmotic with citrated plasma.

When albumin solution is administered to patients with normal blood volume, particular attention should be given to the rate of infusion so that the plasma volume is not expanded too rapidly.

(b) *Standard dose: Urgent restoration of blood volume:* In the emergency treatment of shock, the amount of albumin and duration of therapy must be based on the responsiveness of the patient as indicated by blood pressure, central venous pressure, degree of pulmonary congestion and haematocrit. The initial dose may be followed by additional albumin within 15–30 minutes if the response is deemed inadequate. If there has been considerable loss of blood, transfusion with whole blood is indicated, or if there is continued loss of protein, blood or plasma it may also be desirable to give whole blood and/or other blood fractions.

Burns: Albuminar-5 may be used to prevent marked haemoconcentration and to maintain appropriate electrolyte balance. An optimal regimen involving the use of albumin, crystalloids and water has not been established. Suggested therapy in the treatment of burns includes administration of large volumes of crystalloid solution during the first 24 hours to maintain an adequate plasma volume, even when albumin is infused. Continuation of therapy beyond 24 hours usually requires more albumin and less crystalloid solution. Duration of treatment varies depending on the extent of protein loss through renal excretion, denuded areas of skin and decreased albumin synthesis. Attempts to raise the albumin level above 40 g/litre may only result in an increased rate of catabolism.

Conditions associated with hypoproteinaemia: In these conditions, 1,000 to 1,500 ml of Albuminar-5 may be required to reduce oedema and to bring serum protein values to normal. Since such patients usually have approximately normal blood volume, doses of more than 500 ml of Albuminar-5 should not be given faster than 500 ml in 30–45 minutes to avoid circulatory embarrassment. If slower administration is desired, e.g. in patients with hypertension or cardiac insufficiency, 1,000 ml of Albuminar-5 may be administered by continuous drip at a rate of 100 ml of this solution per hour. Unless the pathological condition responsible for the hypoproteinaemia can be corrected, albumin in any form can afford only symptomatic or supportive relief. The 5% solution should not be administered in situations where sodium restriction is imperative.

Therapeutic plasma exchange: In plasma exchange procedures the volume of plasma removed may be replaced with an equivalent volume of Albuminar-5.

(c) *Children:* The amount of albumin given and the duration of therapy must be determined by the child's condition, response and other parameters, as stated under 'Standard Dose'. However, when treating children, their body weight should also be taken into account.

Use in pregnancy: There is some experience of albumin

being used in the treatment of pre-eclampsia and eclampsia. However, there is very little experience of the use of albumin in the early stages of pregnancy. There is no evidence either in human pregnancy or in animal work that administration of albumin is free from hazard.

Pharmacology: Action: Albuminar-5 is active osmotically and is therefore important in regulating the volume of circulating blood. When the circulating blood volume has been depleted, the haemodilution following albumin administration persists for many hours. In individuals with normal blood volumes, it usually lasts only a few hours.

Contra-indications, warnings, etc *Contra-indications:* Albuminar-5 may be contra-indicated in patients with severe anaemia or cardiac failure.

Precautions: If dehydration is present additional fluids must accompany or follow the administration of Albuminar-5.

The rise in blood pressure which may follow rapid administration of albumin necessitates careful observation of the injured patient to detect bleeding points, which failed to bleed at the lower blood pressure; otherwise new haemorrhage and shock may occur.

Albuminar-5 should be administered with caution to patients with low cardiac reserve or with no albumin deficiency, because a rapid increase in plasma volume may cause circulatory embarrassment or pulmonary oedema. In cases of hypertension or cardiac insufficiency, a slower rate of administration is desirable, at a rate of 5 g of albumin (100 ml) per hour. A careful watch must be kept for the possible development of pulmonary oedema. Should pulmonary oedema occur, the infusion must be stopped immediately.

Warnings and adverse effects: Do not use if the solution is turbid or contains a deposit. Since the solution contains no preservative, it should be used within 3 hours after entering the vial.

The incidence of adverse reactions to Normal Serum Albumin (Human) 5% is low, although nausea, vomiting, increased salivation and febrile reactions may occasionally occur.

Toxicity and treatment of overdosage: Administration of large quantities of albumin should be supplemented with red cell concentrates or replaced by whole blood to combat the relative anaemia which would follow such use. If circulatory embarrassment or pulmonary oedema should develop, the infusion must be stopped immediately and specific treatment given.

Pharmaceutical precautions

(a) *Presentation and Composition:* Albuminar-5 is a sterile, clear, brownish, slightly viscous aqueous solution of human serum albumin. It is stabilised with 0.004 M sodium acetyltryptophanate and 0.004 M sodium caprylate and the pH of the solution is adjusted with sodium bicarbonate or acetic acid. The solution contains approximately 130–160 mmol/l of sodium and not more than 1 mmol/l of potassium. The solution contains no preservative.

(b) *Storage:* Albuminar-5 should be stored at a temperature between 2° and 25°C. Freezing will not harm the solution, but might damage the container and allow contamination of the contents.

Protect solution from light.

When stored as directed Albuminar-5 has a shelf-life of 3 years.

Legal category POM.

Package quantities

Albuminar-5 is supplied as a 5% solution in:

- 250 ml glass vials containing 12.5 grams of albumin
- 500 ml glass vials containing 25.0 grams of albumin
- 1,000 ml glass vials containing 50.0 grams of albumin.

Further information Albuminar-5 is prepared from blood that was non-reactive for hepatitis B surface antigen (HBsAg) when tested with licensed reagents. The likelihood of the presence of viable hepatitis viruses has been further minimised by pasteurising the product at 60°C for 10 hours. Such treatment has been shown to be effective in this respect even when prepared from plasma known to be infective and albumin so prepared, unlike whole blood or plasma, is considered free of the danger of homologous serum hepatitis. Albuminar-5 may be given in conjunction with other parenteral fluids, such as whole blood, plasma, saline, dextrose, or sodium lactate. It is convenient to use, since no cross-matching is required and the absence of cellular elements removes the danger of sensitisation with repeated infusions.

Albuminar-5 contains none of the recognised components of the clotting mechanism of normal blood or plasma. It does not interfere with the normal clotting of blood.

Product licence number 0231/0056.

ALBUMINAR-20

Presentation Albuminar-20 is a sterile aqueous solution of Normal Serum Albumin (Human) 20% obtained from large pools of adult human venous plasma. Each 100 ml of Albuminar-20 contains 20 g of human serum albumin which is osmotically equivalent to 400 ml of normal human plasma.

The product conforms to the monograph for Human Albumin BP.

Indications Albuminar-20 is indicated in: The emergency treatment of shock and in other conditions where the restoration of blood volume is urgent.

Serious burns to prevent haemoconcentration and to combat fluid and sodium losses.

Clinical situations associated with low plasma protein (hypoproteinaemia) with or without oedema.

As an adjunct to exchange transfusion for the treatment of hyperbilirubinaemia in haemolytic disease of the newborn.

In priming heart lung machines for cardiopulmonary by-pass surgery.

Dosage and administration

(a) **Administration:** Albuminar-20 is for intravenous infusion.

Albuminar-20 may be given intravenously without dilution or it may be diluted with normal saline or 5% dextrose before administration, 250 ml per litre gives a solution which is approximately isotonic and isosmotic with citrated plasma.

When undiluted albumin solution is administered to patients with normal blood volume, particular attention should be given to the rate of infusion so that the plasma volume is not expanded too rapidly.

(b) **Standard dose:** *Urgent restoration of blood volume:* In these conditions effectiveness of Albuminar-20 depends on its ability to draw tissue fluid into the blood stream, when such fluid is available. Therefore, if dehydration is present, other fluids must be administered

by any available route, either with albumin or following it. In the emergency treatment of shock, the amount of albumin and duration of therapy must be based on the responsiveness of the patient as indicated by blood pressure, central venous pressure, degree of pulmonary congestion and haematocrit. The initial dose may be followed by additional albumin within 15–30 minutes if the response is deemed inadequate. If there has been considerable loss of blood, transfusion with whole blood is indicated, or if there is continued loss of protein, blood or plasma it may also be desirable to give whole blood and/or other blood fractions.

Burns: Albuminar-20 may be used in conjunction with normal saline or dextrose to prevent marked haemoconcentration and to maintain appropriate electrolyte balance. An optimal regimen involving the use of albumin, crystalloids and water has not been established. Suggested therapy in the treatment of burns includes administration of large volumes of crystalloid solution during the first 24 hours to maintain an adequate plasma volume, even when albumin is infused. Continuation of therapy beyond 24 hours usually requires more albumin and less crystalloid solution. Duration of treatment varies depending on the extent of protein loss through renal excretion, denuded areas of skin and decreased albumin synthesis. Attempts to raise the albumin level above 40 g/litre may only result in an increased rate of catabolism.

Conditions associated with hypoproteinaemia: In these conditions, 200 to 300 ml of Albuminar-20 may be required to reduce oedema and to bring serum protein values to normal. Since such patients usually have approximately normal blood volume, doses of more than 100 ml of Albuminar-20 should not be given faster than 100 ml in 30–45 minutes to avoid circulatory embarrassment. If slower administration is desired, e.g. in patients with hypertension or cardiac insufficiency, 250 ml of Albuminar-20 may be mixed with 250 ml of 10% dextrose solution and administered by continuous drip at a rate of 100 ml of this dextrose solution per hour. Unless the pathological condition responsible for the hypoproteinaemia can be corrected, albumin in any form can afford only symptomatic or supportive relief.

Hyperbilirubinaemia in haemolytic disease of the newborn: In neonates, with serum bilirubin levels above 20 mg per 100 ml severe cerebral damage can develop due to kernicterus. In hypoalbuminaemia the reserve binding capacity for bilirubin is decreased and consequently bilirubin toxicity increases and with it the risk of cerebral damage. The risk of cerebral damage can be reduced by correction of the bilirubin binding capacity with Albuminar-20.

If immediate protection of the patient is required an intravenous injection of 1.0–1.5 g/kg albumin (5–7 ml Albuminar-20/kg bodyweight) can be given. Following this injection the exchange transfusion procedure should be instituted within 6 hours.

If albumin is intended for increasing the removal of bilirubin during exchange transfusion, it is suggested that 1.5–2.5 g albumin (7–12 ml Albuminar-20) is added to each 100 ml donor blood during exchange transfusion.

In Priming Heart Lung Machines for Cardiopulmonary By-Pass Surgery: Pre-operative dilution of the blood by use of a pump prime consisting of only albumin and crystalloid has been shown to be well tolerated during clinical studies. An albumin concentration of 5 g per cent has been widely used. A commonly employed pro-

gramme is an albumin and crystalloid pump prime adjusted so as to achieve a haematocrit reading of 20 per cent and a plasma albumin level of 2.5 g/100 ml in the patient.

(c) *Children:* The amount of albumin given and the duration of therapy must be determined by the child's condition, response and other parameters, as stated under 'Standard Dose'. However, when treating children, their body weight should also be taken into account.

Use in pregnancy: There is some experience of albumin being used in the treatment of pre-eclampsia and eclampsia. However, there is very little experience of the use of albumin in the early stages of pregnancy. There is no evidence either in human pregnancy or in animal work that administration of albumin is free from hazard.

Pharmacology: Action: Albuminar-20 is active oncologically and is therefore important in regulating the volume of circulating blood. When injected intravenously, 50 ml of Albuminar-20 draws approximately 3 volumes of additional fluid into the circulation within 15 minutes, except in the presence of marked dehydration. This extra fluid reduces haematocrit and blood viscosity. The degree of volume expansion is dependent on the initial blood volume. When circulating blood volume has been depleted, the haemodilution following albumin administration persists for many hours. In individuals with normal blood volume, it usually lasts only a few hours.

Contra-indications, warnings, etc

Contra-indications: Albuminar-20 may be contra-indicated in patients with severe anaemia or cardiac failure.

Precautions: If dehydration is present additional fluids must accompany or follow the administration of Albuminar-20.

The rise in blood pressure which may follow rapid administration of albumin necessitates careful observation of the injured patient to detect bleeding points, which failed to bleed at the lower blood pressure; otherwise new haemorrhage and shock may occur.

Albuminar-20 should be administered with caution to patients with low cardiac reserve or with no albumin deficiency, because a rapid increase in plasma volume may cause circulatory embarrassment or pulmonary oedema. In cases of hypertension or cardiac insufficiency, a slower rate of administration is desirable: 250 ml of Albuminar-20 may be mixed with 250 ml of 10% dextrose solution and administered at a rate of 10 g of albumin (100 ml) per hour. A careful watch must be kept for the possible development of pulmonary oedema. Should pulmonary oedema occur, the infusion must be stopped immediately.

Warnings and adverse effects: Do not use if the solution is turbid or contains a deposit. Since the solution contains no preservative, it should be used within 3 hours after entering the vial.

The incidence of adverse reactions to Normal Serum Albumin (Human) 20% is low, although nausea, vomiting, increased salivation and febrile reactions may occasionally occur.

Toxicity and treatment of overdosage: Administration of large quantities of albumin should be supplemented with red cell concentrates or replaced by whole blood to combat the relative anaemia which would follow such use.

If circulatory embarrassment or pulmonary oedema should develop, the infusion must be stopped immediately and specific treatment given.

Pharmaceutical precautions

(a) *Presentation and composition:* Albuminar-20 is a sterile, clear, brownish, slightly viscous aqueous solution of human serum albumin. It is stabilised with 0.016 M sodium acetyltryptophanate and 0.016 M sodium caprylate and the pH of the solution is adjusted with sodium bicarbonate or acetic acid. The solution contains not more than 130 mmol/l of sodium and not more than 1 mmol/l of potassium. The solution contains no preservative.

(b) *Storage:* Albuminar-20 should be stored at a temperature between 2° and 25°C. Freezing will not harm the solution, but might damage the container and allow contamination of the contents. Protect solution from light.

When stored as directed, Albuminar-20 has a shelf-life of 3 years.

Legal category POM.

Package quantities Albuminar-20 is supplied as a 20% solution in:

- 50 ml vials containing 10.0 grams of albumin;
- 100 ml vials containing 20.0 grams of albumin.

Further information Albuminar-20 is prepared from blood that was non-reactive for hepatitis B surface antigen (HBsAg) when tested with licensed reagents. The likelihood of the presence of viable hepatitis viruses has been further minimised by pasteurising the product at 60°C for 10 hours. Such treatment has been shown to be effective in this respect even when prepared from plasma known to be infective and albumin so prepared, unlike whole blood or plasma, is considered free of the danger of homologous serum hepatitis.

Albuminar-20 may be given in conjunction with other parenteral fluids, such as whole blood, plasma, saline, dextrose, or sodium lactate. It is convenient to use, since no cross-matching is required with the absence of cellular elements removes the danger of sensitisation with repeated infusions.

Albuminar-20 contains none of the recognised components of the clotting mechanism of normal blood or plasma. It does not interfere with the normal clotting of blood.

Product licence number 0231/0057

ALBUMINAR-25

Presentation Albuminar-25 is a sterile aqueous solution of Normal Serum Albumin (Human) 25% obtained from large pools of adult human venous plasma. Each 100 ml of Albuminar-25 contains 25 g of human serum albumin which is osmotically equivalent to 500 ml of normal human plasma.

The product conforms to the monograph for Normal Serum Albumin (Human) USP.

Indications Albuminar-25 is indicated in: The emergency treatment of shock and in other conditions where the restoration of blood volume is urgent.

Serious burns to prevent haemoconcentration and to combat fluid and sodium losses.

Clinical situations associated with low plasma protein (hypoproteinaemia) with or without oedema.

As an adjunct to exchange transfusion for the treatment of hyperbilirubinaemia in haemolytic disease of the newborn.

In priming heart-lung machines for cardiopulmonary by-pass surgery.

Dosage and administration

(a) *Administration:* Albuminar-25 is for intravenous infusion.

Albuminar-25 may be given intravenously without dilution or it may be diluted with normal saline or 5% dextrose before administration; 200 ml per litre gives a solution which is approximately isotonic and isosmotic with citrated plasma.

When undiluted albumin solution is administered to patients with normal blood volume, particular attention should be given to the rate of infusion so that it is slow enough to prevent too rapid expansion of plasma volume.

(b) *Standard dose: Urgent restoration of blood volume:* In these conditions effectiveness of Albuminar-25 depends on its ability to draw tissue fluid into the blood stream, when such fluid is available. Therefore, if dehydration is present, other fluids must be administered by any available route, either with albumin or following it. In the emergency treatment of shock, the amount of albumin and duration of therapy must be based on the responsiveness of the patient as indicated by blood pressure, central venous pressure, degree of pulmonary congestion and haematocrit. The initial dose may be followed by additional albumin within 15–30 minutes if the response is deemed inadequate. If there has been considerable loss of blood, transfusion with whole blood is indicated, or if there is continued loss of protein, blood or plasma it may also be desirable to give whole blood and/or other blood fractions.

Burns: Albuminar-25 may be used in conjunction with normal saline or dextrose to prevent marked haemoconcentration and to maintain appropriate electrolyte balance. An optimal regimen involving the use of albumin, crystalloids and water has not been established. Suggested therapy in the treatment of burns includes administration of large volumes of crystalloid solution during the first 24 hours to maintain an adequate plasma volume, even when albumin is infused. Continuation of therapy beyond 24 hours usually requires more albumin and less crystalloid solution. Duration of treatment varies depending on the extent of protein loss through renal excretion, denuded areas of skin and decreased albumin synthesis. Attempts to raise the albumin level above 40 g/litre may only result in an increased rate of catabolism.

Conditions associated with hypoproteinaemia: In these conditions, 200 to 300 ml of Albuminar-25 may be required to reduce oedema and to bring serum protein values to normal. Since such patients usually have approximately normal blood volume, doses of more than 100 ml of Albuminar-25 should not be given faster than 100 ml in 30–45 minutes to avoid circulatory embarrassment. If slower administration is desired, e.g. in patients with hypertension or cardiac insufficiency, 200 ml of Albuminar-25 may be mixed with 300 ml of 10% dextrose solution and administered by continuous drip at a rate of 100 ml of this dextrose solution per hour. Unless the pathological condition responsible for the hypoproteinaemia can be corrected, albumin in any form can afford only symptomatic or supportive relief.

Hyperbilirubinaemia in haemolytic disease of the newborn: In neonates with serum bilirubin levels above 20 mg per 100 ml severe cerebral damage can develop due to kernicterus. In hypoalbuminaemia the reserve binding capacity for bilirubin is decreased and conse-

quently bilirubin toxicity increases and with it the risk of cerebral damage. The risk of cerebral damage can be reduced by correction of the bilirubin binding capacity with Albuminar-25.

If immediate protection of the patient is required an intravenous injection of 1.0–1.5 g/kg albumin (4–6 ml Albuminar-25/kg bodyweight) can be given. Following this injection the exchange transfusion procedure should be instituted within 6 hours.

If albumin is intended for increasing the removal of bilirubin during exchange transfusion, it is suggested that 1.5–2.5 g albumin (6–10 ml Albuminar-25) is added to each 100 ml donor blood during exchange transfusion.

In Priming Heart Lung Machines for Cardiopulmonary By-Pass Surgery: Pre-operative dilution of the blood by use of a pump prime consisting of only albumin and crystalloid has been shown to be well tolerated during clinical studies. An albumin concentration of 5 g per cent has been widely used. A commonly employed programme is an albumin and crystalloid pump prime adjusted so as to achieve a haematocrit reading of 20 per cent and a plasma albumin level of 2.5 g/100 ml in the patient.

(c) *Children:* The amount of albumin given and the duration of therapy must be determined by the child's condition, response and other parameters, as stated under 'Standard Dose'. However, when treating children, their body weight should also be taken into account.

Use in pregnancy: There is some experience of albumin being used in the treatment of pre-eclampsia and eclampsia. However, there is very little experience of the use of albumin in the early stages of pregnancy. There is no evidence either in human pregnancy or in animal work that administration of albumin is free from hazard.

Pharmacology: Action: Albuminar-25 is active oncologically and is therefore important in regulating the volume of circulating blood. When injected intravenously, 50 ml of Albuminar-25 draws approximately 175 ml of additional fluid into the circulation within 15 minutes, except in the presence of marked dehydration. This extra fluid reduces haematocrit and blood viscosity. The degree of volume expansion is dependent on the initial blood volume. When circulating blood volume has been depleted, the haemodilution following albumin administration persists for many hours. In individuals with normal blood volume, it usually lasts only a few hours.

Contra-indications, warnings, etc

Contra-indications: Albuminar-25 may be contra-indicated in patients with severe anaemia or cardiac failure.

Precautions: If dehydration is present additional fluids must accompany or follow the administration of Albuminar-25.

The rise in blood pressure which may follow rapid administration of albumin necessitates careful observation of the injured patient to detect bleeding points, which failed to bleed at the lower blood pressure; otherwise new haemorrhage and shock may occur.

Albuminar-25 should be administered with caution to patients with low cardiac reserve or with no albumin deficiency, because a rapid increase in plasma volume may cause circulatory embarrassment or pulmonary oedema. In cases of hypertension or cardiac insufficiency, a slower rate of administration is desirable: 200 ml of Albuminar-25 may be mixed with 300 ml of 10% dextrose solution and administered at a rate of 10 g of albumin (100 ml) per hour. A careful watch must be kept for the possible development of pulmonary oedema.

Should pulmonary oedema occur, the infusion must be stopped immediately.

Warnings and adverse effects: Do not use if the solution is turbid or contains a deposit. Since the solution contains no preservative, it should be used within 3 hours after entering the vial.

The incidence of untoward reactions to Normal Serum Albumin (Human) 20% is low, although nausea, vomiting, increased salivation and febrile reactions may occasionally occur.

Toxicity and treatment of overdosage: Administration of large quantities of albumin should be supplemented with red cell concentrates or replaced by whole blood to combat the relative anemia which would follow such use.

If circulatory embarrassment or pulmonary oedema should develop, the infusion must be stopped immediately and specific treatment given.

Pharmaceutical precautions

(a) **Presentation and composition:** Albuminar-25 is a sterile, clear, brownish, slightly viscous aqueous solution of human serum albumin. It is stabilised with 0.02 M sodium acetyltryptophanate and 0.02 M sodium caprylate and the pH of the solution is adjusted with sodium bicarbonate or acetic acid. The solution contains approximately 130–160 mmol/l of sodium and not more than 1 mmol/l of potassium. The solution contains no preservative.

(b) **Storage:** Albuminar-25 should be stored at a temperature between 2° and 25°C. Freezing will not harm the solution, but might damage the container and allow contamination of the contents. Protect solution from light.

When stored as directed, Albuminar-25 has a shelf-life of 3 years.

Legal category POM.

Package quantities Albuminar-25 is supplied as a 25% solution in:

- 20 ml vials containing 5.0 grams of albumin.
- 50 ml vials containing 12.5 grams of albumin;
- 100 ml vials containing 25.0 grams of albumin.

Further information Albuminar-25 is prepared from blood that was non-reactive for hepatitis B surface antigen (HBsAg) when tested with licensed reagents. The likelihood of the presence of viable hepatitis viruses has been further minimised by pasteurising the product at 60°C for 10 hours. Such treatment has been shown to be effective in this respect even when prepared from plasma known to be infective and albumin so prepared, unlike whole blood or plasma, is considered free of the danger of homologous serum hepatitis.

Albuminar-25 may be given in conjunction with other parenteral fluids, such as whole blood, plasma, saline, dextrose, or sodium lactate. It is convenient to use, since no cross-matching is required and the absence of cellular elements removes the danger of sensitisation with repeated infusions.

Albuminar-25 contains none of the recognised components of the clotting mechanism of normal blood or plasma. It does not interfere with the normal clotting of blood.

Product licence number 0231/0045

CALCITARE*

Presentation For intramuscular or subcutaneous use only. Each vial contains 160 international units porcine calcitonin with a vial of gelatin diluent.

Uses Paget's disease of bone

Hypercalcaemia: The calcium lowering effect of calcitonin is usually rapid. Treatment should be regarded as an adjunct to more specific long-term measures. The fall in serum calcium is more pronounced in hypercalcaemic patients with a raised bone turnover, e.g. Paget's disease and thyrotoxicosis. Treatment may also be beneficial in patients with hypercalcaemia due to immobilisation in Paget's disease, malignancy, vitamin D intoxication and hyperparathyroidism. Calcitonin is of particular value when such patients have concurrent renal or cardiac failure.

Dosage and administration Calcitare can be given subcutaneously or intramuscularly.

1. **Paget's disease of bone:** Clinical and biochemical improvement has been observed with dosage regimens ranging from 80 international units three times a week to 160 international units daily in single or divided doses.

Daily injections of 80 international units or 160 international units are recommended for three to six months in patients with bone pain or nerve compression syndromes.

Clinical improvement is usually seen within three months but may occasionally be delayed for as long as a year. When clinical improvement occurs, an attempt to reduce the dose and/or frequency of injection may be made, consistent with maintaining a remission. Alternatively, treatment can be stopped and restarted at a later date when necessary.

Biochemical improvement is shown by a reduction in serum alkaline phosphatase and urinary hydroxyproline excretion, the fall in urinary hydroxyproline often occurring in a matter of days. The fall in serum alkaline phosphatase occurs in a matter of weeks. Serum alkaline phosphatase and urinary hydroxyproline levels return slowly towards pre-treatment values (at different rates) on withdrawal of calcitonin therapy. Long-term treatment with calcitonin may be needed in those asymptomatic patients with rapidly advancing and potentially disabling disease.

Radiological and histological improvement has also been observed with long-term treatment and this reconstructive action of calcitonin on bone has been shown to be dose-dependent.

When changing from synthetic salmon calcitonin (Calsynar) to porcine calcitonin (Calcitare), 80 international units of Calcitare may be conveniently substituted for 50 international units of Calsynar and 160 international units for 100 international units respectively.

2. **Hypercalcaemia:** The optimum dosage pattern must essentially be gauged by the magnitude of the hypocalcaemic response obtained in a particular patient. In general the greatest response will be observed in cases of rapid bone turnover. Four international units per kg per day of Calcitare may produce a fall in serum calcium. However, larger doses of calcitonin may be necessary, but are inconvenient to administer as Calcitare, in which case treatment with Calsynar is advised.

Contra-indications, warnings and side-effects

Calcitonin may cause nausea, vomiting, facial flushing and tingling of the hands. An unpleasant taste and

inflammatory reactions at the injection site have been reported. The nausea and flushing are usually transient and rarely necessitate withdrawal of treatment. If necessary, the injections can be administered at night with an antiemetic.

In any patient with a history of allergy; a scratch (or intradermal) test should be conducted prior to administration of Calcitare using a 1:100 dilution in Sodium Chloride Injection BP. To detect gelatin sensitivity a similar test should be carried out using gelatin diluent in the same dilution.

Some patients will develop porcine calcitonin binding antibodies after several months of treatment. The antibodies are generally of low titre and are more likely to occur in patients on the higher doses. The development of these antibodies is not usually related to loss of clinical efficacy. It is possible that this may be analogous to treated diabetic patients in whom insulin binding antibodies frequently develop, but who rarely manifest clinical resistance to insulin. The presence of these antibodies appears to bear no relationship to allergic reactions which are very rare. Secondary hyperparathyroidism is not thought to occur following calcitonin therapy.

Reproductive studies performed with salmon calcitonin showed a decrease in foetal birth weight in rabbits when given in doses of 14–56 times the dose recommended for human use. Since calcitonin does not cross the placental barrier this finding may be due to metabolic effects of calcitonin on the pregnant animal. There are no studies in pregnant women. Salmon calcitonin, and by inference porcine calcitonin, should be used only when clearly needed in women who are or who may become pregnant.

Calcitonin has been shown to inhibit lactation in animals and should not be administered to nursing mothers.

Following injections of calcitonin serum calcium levels may be transiently lowered to below normal values. This effect is noted most frequently on therapy where bone turnover is abnormally high, but diminishes as osteoclastic activity is reduced with Calcitare. Whilst this phenomenon does not usually give rise to complications, care should be exercised in patients who are receiving concurrent cardiac glycosides as dosage adjustments of these drugs may be necessary in view of the fact that their effect may be modified by changes in cellular electrolyte concentrations. Trace amounts of T_3/T_4 are present in Calcitare. Experience over a number of years has not revealed any significant metabolic effects due to T_3 and T_4 , when Calcitare has been given at the maximum recommended dose for Paget's disease of 160 international units daily. At higher doses (e.g. 8 i.u./kg) used in the treatment of hypercalcaemia, the amounts of T_3/T_4 normally detected in the product are most unlikely to have any adverse effect, except in highly susceptible patients such as those with significant ischaemic heart disease.

Pharmaceutical precautions Calcitare is presented as a sterile, lyophilised powder providing 160 international units porcine calcitonin per vial. Using aseptic technique the contents of a vial of the freeze-dried powder are reconstituted with an appropriate volume of sterile gelatin diluent so that the final injection volume will be 1–2 ml. Once reconstituted any unused solution should be administered within 24 hours, or if refrigerated (2–10°C) used within seven days.

The lyophilised powder when stored at less than 25°C will retain its potency for three years.

Legal category POM.

Package quantities For intramuscular or subcutaneous use: Boxes of 5 vials Calcitare 160 international units per vial sterile, lyophilised, with 5 vials gelatin diluent, sterile.

Boxes of 10 vials Calcitare 160 international units per vial sterile, lyophilised, with 10 vials gelatin diluent, sterile.

Further information The calcium lowering ability of the calcitonins is measured in international units. The international unit is based on a rat bioassay in which one fortieth of the weight of salmon calcitonin, as compared with weights of porcine and human calcitonin, produces the same fall in serum calcium. The weights of pure calcitonin equivalent to 100 international units in this assay are: human calcitonin, 1 mg, porcine calcitonin, 1 mg, and salmon calcitonin, 0.025 mg.

Product licence number 0231/0011.

CALSYNAR* (SALCATONIN)

Presentation *Multidose vials:* each multidose vial contains 400 international units of synthetic salmon calcitonin in 2 ml of saline acetate diluent (i.e. 200 international units of approximately 0.05 mg synthetic salmon calcitonin per ml). For subcutaneous or intramuscular use only.

Ampoules: each clear glass ampoule contains 100 international units of synthetic salmon calcitonin in 1 ml saline acetate diluent. For subcutaneous or intramuscular use only.

Uses *Paget's disease of bone.*

Hypercalcaemia: The calcium lowering effect of calcitonin is usually rapid. Treatment should be regarded as an adjunct to more specific long-term measures. The fall in serum calcium is more pronounced in hypercalcaemic patients with a raised bone turnover, e.g. Paget's disease and thyrotoxicosis. Treatment may also be beneficial in patients with hypercalcaemia due to immobilisation in Paget's disease, malignancy, vitamin D intoxication and hyperparathyroidism.

Calcitonin is of particular value when such patients have concurrent renal or cardiac failure.

Pain associated with advanced metastatic bone cancer: The use of Calsynar has been reported to be beneficial in the relief of pain in some patients with advanced metastatic bone cancer.

Dosage and administration (a) *Paget's disease of bone:* Clinical and biochemical improvement has been observed with dosage regimens ranging from 50 international units three times a week to 100 international units daily in single or divided doses.

Daily injections of 50 international units or 100 international units are recommended for three to six months in patients with bone pain or nerve compression syndromes.

Clinical improvement is usually seen within three months but may occasionally be delayed for as long as a year. When clinical improvement occurs an attempt to reduce the dose and/or frequency of the injections may be made consistent with maintaining a remission.

Alternatively, treatment can be stopped and restarted at a later date when necessary.

Biochemical improvement is shown by a reduction in serum alkaline phosphatase and urinary hydroxyproline excretion, the fall in urinary hydroxyproline often occurring in a matter of days, the fall in serum alkaline phosphatase occurring in a matter of weeks. Serum alkaline phosphatase and urinary hydroxyproline levels return slowly towards pre-treatment values (at different rates) on withdrawal of calcitonin therapy. Long-term treatment with calcitonin may be needed in those asymptomatic patients with rapidly advancing and potentially disabling disease.

Radiological and histological improvement has also been observed with long-term treatment and this reconstructive action of calcitonin on bone has been shown to be dose-dependent.

When changing from porcine calcitonin (Calcitare) to synthetic salmon calcitonin (Calsynar) 50 international units of Calsynar may be conveniently substituted for 80 international units of Calcitare and 100 international units for 160 international units of Calcitare.

(b) *Hypercalcaemia*: Calsynar should be given by subcutaneous or intramuscular injection. Treatment should be adjusted to the patient's clinical and biochemical response.

Severe hypercalcaemia may require high doses of Calsynar and initially 400 international units may be given six or eight-hourly. Lower doses may be satisfactory in some patients and dosage may be adjusted according to the patient's clinical and biochemical response. There is no additional benefit to be gained from doses in excess of 8 international units per kg six-hourly.

(c) *Pain associated with advanced metastatic bone cancer*: The use of Calsynar has been reported to be beneficial in the relief of pain in some patients with advanced metastatic bone cancer. Subcutaneous or intramuscular administration of 200 iu six-hourly for 48 hours has been shown to be effective in some patients and to permit reduction in the dose of concomitantly administered analgesics. Relief of pain may last for one week or longer. Treatment may be repeated at the discretion of the physician.

Contra-indications, warnings and side-effects

Calcitonin may cause nausea, vomiting, facial flushing, tingling of the hands, and an unpleasant taste. Inflammatory reactions at the injection site have been reported. The nausea and flushing are usually transient and rarely necessitate withdrawal of treatment. If necessary, the injections can be administered at night with an antiemetic.

In any patient with a history of allergy, a scratch (or intradermal) test should be conducted prior to administration of Calsynar using a 1:100 dilution in Sodium Chloride Injection BP.

Some patients will develop salmon calcitonin binding antibodies after several months of treatment. The antibodies are generally of low titre and are more likely to occur in patients on the higher doses. The development of these antibodies is not usually related to loss of clinical efficacy. It is possible that this may be analogous to treated diabetic patients in whom insulin binding antibodies frequently develop, but who rarely manifest clinical resistance to insulin. The presence of antibodies appears to bear no relationship to allergic reactions which are very rare.

Secondary hyperparathyroidism is not thought to occur following calcitonin therapy.

Salmon calcitonin has been shown to cause decrease in foetal birth weight in rabbits when given in doses of 14–56 times the dose recommended for human use. Since calcitonin does not cross the placental barrier this finding may be due to metabolic effects of calcitonin on the pregnant animal. Studies have not been carried out in pregnant women. Whenever possible, treatment should be avoided in women of child-bearing potential.

Calcitonin has been shown to inhibit lactation in animals and should not be administered to nursing mothers.

Following injections of calcitonin serum calcium levels may be transiently lowered to below normal values. This effect is noted most frequently on initiation of therapy where bone turnover is abnormally high, but diminishes as osteoclastic activity is reduced with Calsynar. Whilst this phenomenon does not usually give rise to complications, care should be exercised in patients who are receiving concurrent cardiac glycosides as dosage adjustments of these drugs may be necessary in view of the fact that their effect may be modified by changes in cellular electrolyte concentrations.

Pharmaceutical precautions Calsynar multidose vials contain a sterile solution of 400 international units of synthetic salmon calcitonin in 2 ml of saline acetate diluent per vial. Calsynar multidose vials, when stored between 2–10°C will retain their potency for 3 years. Do not freeze.

Calsynar ampoules contain a sterile solution of 100 international units of synthetic salmon calcitonin in 1 ml saline acetate diluent. Calsynar ampoules 100 international units when stored between 2–10°C will retain their potency for two years. Do not freeze.

Legal category POM.

Package quantities For subcutaneous or intramuscular use only:

Boxes of 1 multidose vial of Calsynar 400 international units per vial in 2 ml saline acetate diluent.

Cartons of six ampoules and 10 ampoules, each ampoule containing 100 international units in 1 ml saline acetate diluent.

Further information The calcium lowering ability of the calcitonins is measured in international units. The international unit is based on a rat bioassay in which one fortieth of the weight of salmon calcitonin, as compared with weights of porcine and human calcitonin, produces the same fall in serum calcium. The weights of pure calcitonin equivalent to 100 international units in this assay are approximately: human calcitonin, 1 mg, porcine calcitonin, 1 mg and salmon calcitonin, 0.025 mg.

Multidose vials – 0231/0027.

Ampoules – 0231/0055.

CHYMOCYCLAR*

Presentation Each pink, gelatin capsule contains:

50,000 Armour units of proteolytic activity supplied by a purified enzyme concentrate containing trypsin and chymotrypsin.

250 mg Tetracycline Hydrochloride BP.

Uses Infections due to tetracycline-sensitive organisms.

Dosage and administration

For administration to adults only: One or two capsules to be taken four times a day, half an hour before meals. The capsules should be swallowed whole since damage to the enteric coated core results in loss of proteolytic activity.

Absorption of tetracycline is impaired by the concomitant administration of food or drugs of high calcium content.

Contra-indications, warnings, etc

Precautions: In the presence of renal or hepatic impairment accumulation of tetracycline may occur and special attention to dosage is necessary. If possible, serum antibiotic levels should be controlled in such patients. Special care should be exercised with the use of tetracycline during pregnancy.

Side-effects: Tetracycline is known to produce gastrointestinal disturbances and may facilitate monilial infection in some cases. Although no specific reports relating to Chymocyclar have been received, tetracycline has been recorded as causing haemolytic anaemia, eosinophilia, thrombocytopenia, hepatotoxicity, allergic skin reactions and photosensitivity.

Tetracycline has also been reported to reduce the efficacy of oral steroid contraceptives.

Contra-indications: Patients with known sensitivities to enzymes and tetracycline. During the period of tooth development, last trimester of pregnancy and early childhood, it is possible that tetracycline may cause yellowish brown discolouration of the teeth and enamel hyperplasia in prolonged high dosage.

Pharmaceutical precautions Chymocyclar should be stored in a cool dry place, protected from light – Shelf-life 3 years.

Legal category POM.

Package quantities Bottles of 30, 100 and 500 capsules.

Further information In conditions where inflammatory oedema is associated with infections, the administration of the proteolytic enzymes may be directly advantageous, and the beneficial clinical results obtained with combination therapy of this nature have been reported in the literature.

Product licence number 0231/5001.

**CHYMORAL®
CHYMORAL® FORTE**

Presentation Enteric-coated tablets containing a purified proteolytic enzyme concentrate providing trypsin and chymotrypsin activity.

Chymoral – 50,000 Armour units.

Chymoral Forte – 100,000 Armour units.

Uses Resolution of acute, inflammatory oedema associated with: Accidental and surgical trauma. Episiotomies. Intervertebral disc herniation (sciatica). Thrombophlebitis. Vasectomies. Reduction in viscosity of mucus and sputum associated with bronchitis, rhinitis and sinusitis.

Dosage and administration *Chymoral:* 2 tablets four times a day. Children 1 tablet four times a day.

Chymoral Forte: 1 tablet four times a day. Not for administration to children.

The tablets must be taken half an hour before meals and swallowed whole without crushing, since damage to the enteric coating rapidly causes loss of potency.

Contra-indications, warnings, etc

Precautions: Patients with known sensitivity to enzymes.

After many years of widespread clinical use, there is no reason to believe that Chymoral is, or may be, teratogenic in humans. However, it is a sound medical principle to exercise precaution in prescribing any medication during the first three months of pregnancy.

Side-effects: Occasional slight gastric disturbance.

Pharmaceutical precautions The tablets should be stored in a cool dry place – shelf-life is three years for Chymoral and two years for Chymoral Forte.

Legal category P.

Package quantities *Chymoral:* Bottles of 50 and 500 tablets.

Chymoral Forte: Bottles of 30, 200 and 500 tablets.

Further information Nil.

Chymoral 0231/5021

Chymoral Forte 0231/5020

DIORALYTE®

Presentation Foil/laminate sachets each containing:

Sodium Chloride BP	0.20 g
Potassium Chloride BP	0.30 g
Sodium Bicarbonate BP	0.30 g
Dextrose Monohydrate BP	8.00 g

Uses Oral correction of fluid and electrolyte loss in infants, children and adults. In the treatment of watery diarrhoea of varying aetiologies, including gastroenteritis, in all age groups.

The product has been formulated to treat fluid and electrolyte loss associated with infantile diarrhoea, but is also appropriate for the treatment of older children and adults.

Dosage and administration *Reconstitution:* The contents of each sachet should be dissolved in sufficient freshly boiled and cooled water to make up to 200 ml (approximately 7 fluid ounces). An infant's feeding bottle is a convenient measure of this volume. The solution should be made up immediately prior to feeding and any solution remaining an hour after reconstitution should be discarded. However, the solution may be used for up to 24 hours if stored in a refrigerator immediately after reconstitution.

The reconstituted solution must not be boiled.

Dosage: For oral administration only.

The volume of reconstituted Dioralyte needed each day should be determined by the physician, taking into account the weight of the patient and severity of the condition.

For the treatment of infantile diarrhoea, a number of different regimens are used by different physicians, but the basic principle is to stop all foods including milk initially, whilst maintaining adequate fluid intake. Milk can then be reintroduced to provide calories, but to avoid worsening or prolonging the diarrhoea this should be gradual. A suggested regimen for the treatment of severe

infantile diarrhoea based on body weight in kilograms is given below.

Day	Volume of Dioralyte solution (ml)	Volume of milk (ml)	Total volume in 24 hours (ml)
1	150 × wt†	0	150 × wt
2	120 × wt	30 × wt	150 × wt
3	90 × wt	60 × wt	150 × wt
4	60 × wt	90 × wt	150 × wt
5	30 × wt	120 × wt	150 × wt
6	0	150 × wt	150 × wt

† Weight in kilograms.

Simplified dosage scheme: Alternatively, for milder cases, the following simplified regimen may be adopted.

During the first 24–28 hours, the infant is offered Dioralyte in the same quantities as are used for the usual feeds. When the vomiting and diarrhoea have subsided, the Dioralyte solution is substituted with half strength milk feeds. Normal feeding may be resumed as the appetite returns. For toddlers and older children, Dioralyte may be given freely until the thirst is satisfied.

These dosage schemes are only a general guide and the volume of Dioralyte per feed and the speed of re-introduction of milk or other feeds is at the discretion of the physician.

In those patients who are vomiting at the start of treatment, it may be advisable to offer very small volumes initially until vomiting is under control. If the vomiting and diarrhoea show no sign of moderating the patient should be reassessed.

Diarrhoea is uncommon in breast fed infants. However, if treatment with Dioralyte becomes necessary it is suggested that for each feed the chosen regimen is followed, such that the infant is given the appropriate volume of Dioralyte for that feed and then put to the breast until satisfied. Expression of residual milk from the breasts may be necessary during this period.

Contra-indications, warnings, etc

Warnings: For oral administration only.

The contents of each sachet should always be made up to 200 ml with freshly boiled and cooled water (the product must not be reconstituted in diluents other than water, e.g. must not be included in milk solutions). A weaker solution than recommended will fail to provide adequate sugar and electrolytes and a stronger solution than recommended may give rise to hypernatraemia.

The reconstituted solution must not be boiled.

Contra-indications: There are no known contra-indications to Dioralyte. However, there may be a number of conditions where treatment with Dioralyte will be inappropriate, e.g. intestinal obstruction requiring surgical intervention.

Pharmaceutical precautions The sachet should be stored in a cool, dry place.

Legal category P.

Package quantities Cartons containing 20 sachets, together with a professional package insert and two tear-off Patient Instruction leaflets.

Cartons of 4 sachets with patient instruction leaflet.

Further information Dioralyte (Glucose Electrolyte Supplement) is Compound Sodium Chloride and Dextrose Oral Powder BP.

A litre of made up solution (5 sachets, 5 × 200 ml

quantities) contains: 35 mmol Sodium (Na⁺); 20 mmol Potassium (K⁺); 37 mmol Chloride (Cl⁻); 18 mmol Bicarbonate (HCO₃⁻); 200 mmol Dextrose. The total osmolality is 310 mmol per litre.

Product licence number 0231/0043.

FACTORATE*

Presentation Dried Human Antihaemophilic Fraction Factorate is a stable lyophilised concentrate of Factor VIII (AHF, AHG) prepared from pooled human plasma.

Each vial contains the labelled amount of antihaemophilic activity in International Units (one International Unit is the activity equivalent to the average Factor VIII content of 1 ml aliquots of 167 samples of fresh normal plasma, as determined in an international collaborative study). Each vial also contains sufficient sodium chloride to make the reconstituted solution approximately isotonic when sterile Water for Injections BP is added as directed.

Uses For use in therapy of classic haemophilia (Haemophilia A).

Dosage and administration Factorate is for intravenous administration only. As a general rule one unit of Factor VIII activity per kg will increase by 2% the circulating Factor VIII level, and although dosage must be adjusted according to the needs of the patient (weight, severity of haemorrhage, presence of inhibitors) the following general dosages are suggested.

1. **Overt bleeding:** Initially 20 units per kg of body weight followed by 10 units per kg every eight hours for the first 24 hours and the same dose every 12 hours for the next 3 or 4 days. For massive wounds, give until bleeding stops and maintain with 20 units per kg 8-hourly to achieve a minimum Factor VIII level of 40%.

2. **Muscle haemorrhages:** (a) Minor haemorrhages in extremities or non-vital areas: 10 units per kg once a day for 2 or 3 days.

(b) Massive haemorrhages in non-vital areas: 10 units per kg by infusion at 12 hour intervals for 2 days and then once a day for 2 more days.

(c) Haemorrhages near vital organs (neck, throat, subperitoneal): 20 units per kg, initially; then 10 units per kg every 8 hours. After 2 days the dose may be reduced by one-half.

3. **Joint haemorrhages:** 10 units per kg every 8 hours for a day; then twice daily for 1 or 2 days. If aspiration is carried out, 10 units per kg just prior to aspiration with additional infusions of 10 units per kg 8 hours later and again on the following day.

4. **Surgery:** Dosages of 30 to 40 units per kg body weight prior to surgery are recommended. After surgery 20 units per kg every 8 hours should be administered. Close laboratory control to maintain the blood level of Factor VIII above 40% of normal for at least 10 days post-operatively is suggested.

5. **Dental extractions:** For simple extractions a pre-operative dose of 20–25 units per kg sufficient to raise the Factor VIII level to 50% should be given, followed by intravenous administration of epsilon aminocaproic acid. For multiple extractions further doses of Factor VIII may be advisable 24 or 36 hours after the operation.

Recommended reconstitution: Reconstitute Factorate using 20 ml sterile Water for Injections BP using standard aseptic precautions.

Warm both diluent and Factorate vials to between 20°C and 25°C. Direct diluent down the side of the vial and gently rotate the vial until contents are dissolved. **DO NOT SHAKE VIAL.** Vigorous shaking will cause frothing and prolong the reconstitution time. Complete solution usually takes less than 5 minutes. The solution is now ready for administration. If a gel forms on reconstitution, the preparation should not be used.

Administration: Standard aseptic techniques should be used at all times.

Intravenous injection: Plastic disposable syringes are recommended with Factor VIII solution. The ground glass surfaces of all-glass syringes tend to stick with solutions of this type.

1. Attach a filter needle to a sterile disposable syringe. Insert filter needle into stopper of Factor VIII vial; inject air and withdraw the reconstituted solution from the vial.

2. Discard the filter needle and attach a suitable intravenous needle.

3. Administer solution by slow intravenous injection (20 ml in about five minutes).

Intravenous infusion: The infusion equipment used should comply with that described in sections 3 or 4 of British Standard 2463:1962, Transfusion Equipment for Medical Use.

1. Prepare solution of Factorate as recommended under 'Reconstitution'.

2. Attach suitable infusion set.

3. If more than one vial is to be administered to the same patient the infusion set may be transferred to the second vial.

4. When infusion of Factorate is complete, the infusion set may be flushed with sterile isotonic saline to avoid loss of any of the reconstituted solution.

5. After use, discard infusion set, needles and vials together with any unused solution.

Contra-indications, warnings, etc

Warning: Factor VIII is prepared from human plasma, each donation of which has been found negative for hepatitis B surface antigen (HBsAg) by the radioimmunoassay (RIA) method. In addition, each batch, after reconstitution as recommended, has been tested and found negative by the RIA method. However, since no completely reliable laboratory test is yet available to detect all potentially infectious plasma donations, the risk of transmitting viral hepatitis is still present.

Side-effects: Products of this type are known to cause mild chills, nausea or stinging at the infusion site.

Contra-indications: There are no known contra-indications to antihæmophilic fraction.

Precautions: Factor VIII contains low levels of group A and B isohaemagglutinins. When large volumes are given to patients of blood groups A, B or AB, the possibility of intravascular haemolysis should be considered. Such patients should be monitored by means of a haematocrit and direct Coombs test for signs of progressive anaemia.

Pharmaceutical precautions Factorate is to be stored at refrigerator temperature (2°C–6°C). When stored as directed, it will maintain its labelled potency for the dating period indicated on the label but within this period may be stored at room temperature (not exceeding 30°C or 86°F) for up to six months.

Legal category POM.

Package quantities Factorate is supplied in single dose vials (potency is stated on each vial label).

Further information Haemophilia A, a hereditary disorder of blood coagulation occurring almost exclusively in males results in profuse bleeding in joints, muscles or internal organs as a result of minor trauma. The disease appears to be due to a deficiency of a specific plasma protein, antihæmophilic factor, Factor VIII: Factorate provides temporary replacement of the missing clotting factor.

Affected individuals frequently require therapy following minor trauma. Surgery, when required in such individuals must be preceded by temporary correction of the clotting abnormality with fresh plasma transfusions, cryoprecipitate or by injections of Factor VIII concentrates. Obvious advantages of the use of concentrates of Factor VIII are the avoidance of hyper-proteinaemia, overloading the circulatory system and possible kidney dysfunction resulting from large volume transfusions.

Several different concentrations of Factor VIII have been used successfully. These range from Fraction 1 of Cohn to highly purified potent preparations. Dried Human Antihæmophilic Fraction – Factorate is in an intermediate category, being purified cryoglobulin complying with the standards of the BP.

Product licence number 0231/0038.

HIGH POTENCY FACTORATE*

Presentation Dried Human Antihæmophilic Fraction High Potency Factorate is a stable lyophilised concentrate of Factor VIII (AHF, AHG) prepared from pooled human plasma. It conforms to the monograph for Dried Human Antihæmophilic Factor BP.

Each vial contains the labelled amount of antihæmophilic activity in International Units (one International Unit is the activity equivalent to the average Factor VIII content of 1 ml aliquots of 167 samples of fresh normal plasma, as determined in an international collaborative study). Each vial also contains sufficient sodium chloride to make the reconstituted solution approximately isotonic when Water for Injections BP is added as directed.

Uses For use in therapy of classic haemophilia (Haemophilia A).

Dosage and administration High Potency Factorate is for intravenous administration only. As a general rule one unit of Factor VIII activity per kg will increase by 2% the circulating Factor VIII level, and although dosage must be adjusted according to the needs of the patient (weight, severity of haemorrhage, presence of inhibitors) the following general dosages are suggested.

1. **Overt bleeding:** Initially 20 units per kg of body weight followed by 10 units per kg every eight hours for the first 24 hours and the same dose every 12 hours for the next 3 or 4 days. For massive wounds, give until bleeding stops and maintain with 20 units per kg 8-hourly to achieve a minimum Factor VIII level of 40%.

2. **Muscle haemorrhages:** (a) Minor haemorrhages in extremities or non-vital areas: 10 units per kg once a day for 2 or 3 days.

- (b) Massive haemorrhages in non-vital areas: 10 units per kg by infusion at 12 hour intervals for 2 days and then once a day for 2 more days.

- (c) Haemorrhages near vital organs (neck, throat, subperitoneal), 20 units per kg, initially; then 10 units per kg every 8 hours. After 2 days the dose may be reduced by one-half.

3. **Joint haemorrhages:** 10 units per kg every 8 hours for a day; then twice daily for 1 or 2 days. If aspiration is

carried out, 10 units per kg just prior to aspiration with additional infusions of 10 units per kg 8 hours later and again on the following day.

4. Surgery: Dosages of 30 to 40 units per kg body weight prior to surgery are recommended. After surgery 20 units per kg every 8 hours should be administered. Close laboratory control to maintain the blood level of Factor VIII above 40% of normal for at least 10 days post-operatively is suggested.

5. Dental extractions: For simple extractions a pre-operative dose of 20–25 units per kg sufficient to raise the Factor VIII level to 50% should be given, followed by intravenous administration of tranexamic acid. For multiple extractions further doses of Factor VIII may be advisable 24 or 36 hours after the operation.

Recommended reconstitution: Reconstitute High Potency Factorate using 30 ml sterile Water for Injections BP using standard aseptic precautions.

Warm both diluent and High Potency Factorate vials to between 20°C and 30°C. Direct diluent down the side of the vial and gently rotate the vial until contents are dissolved. **DO NOT SHAKE VIAL.** Vigorous shaking will cause frothing and prolong the reconstitution time. Complete solution usually takes approximately 10 minutes. The solution is now ready for administration. If a gel forms on reconstitution, the preparation should not be used. The solution should be used within 3 hours of reconstitution.

Administration: Standard aseptic techniques should be used at all times.

Intravenous injection: Plastic disposable syringes are recommended with Factor VIII solution. The ground glass surfaces of all-glass syringes tend to stick with solutions of this type.

1. Attach a filter needle to a sterile disposable syringe. Insert filter needle into stopper of Factor VIII vial; inject air and withdraw the reconstituted solution from the vial.

2. Discard the filter needle and attach a suitable intravenous needle.

3. Administer solution by slow intravenous injection, at a rate comfortable to the patient, and not exceeding 2 ml per minute.

Intravenous infusion: The infusion equipment used should comply with that described in sections 3 or 4 of British Standard 2463:1962, Transfusion Equipment for Medical Use.

1. Prepare solution of High Potency Factorate as recommended under 'Reconstitution'.

2. Attach suitable infusion set.

3. If more than one vial is to be administered to the same patient the infusion set may be transferred to a second vial.

4. When infusion of High Potency Factorate is complete, the infusion set may be flushed with sterile isotonic saline to avoid loss of any of the reconstituted solution.

5. After use, discard infusion set, needles and vials together with any unused solution.

Contra-indications, warnings, etc

Warning: Factor VIII is prepared from human plasma, each donation of which has been found negative for hepatitis B surface antigen (HBsAg) by the radio-immunoassay (RIA) method. In addition, each batch, after reconstitution as recommended, has been tested and found negative by the RIA method. However, since no completely reliable laboratory test is yet available to

detect all potentially infectious plasma donations, the risk of transmitting viral hepatitis is still present.

Side-effects: Products of this type are known to cause mild chills, nausea or stinging at the infusion site.

Contra-indications: There are no known contra-indications to antihaemophilic fraction.

Precautions: Factor VIII contains low levels of group A and B isohaemagglutinins. When large volumes are given to patients of blood groups A, B or AB, the possibility of intravascular haemolysis should be considered. Such patients should be monitored by means of a haematocrit and direct Coombs test for signs of progressive anaemia.

Pharmaceutical precautions High Potency Factorate is to be stored at refrigerator temperature (2°C–6°C). When stored as directed, it will maintain its labelled potency for the period indicated on the label but within this period it may be stored at room temperature (not exceeding 30°C or 86°F) for up to six months.

Legal category POM.

Package quantities High Potency Factorate is supplied in single dose vials (potency is stated on each vial label).

Further information Haemophilia A, a hereditary disorder of blood coagulation occurring almost exclusively in males results in profuse bleeding in joints, muscles or internal organs as a result of minor trauma. The disease appears to be due to a deficiency of a specific plasma protein, antihaemophilic factor, Factor VIII; High Potency Factorate provides temporary replacement of the missing clotting factor.

Affected individuals frequently require therapy following minor trauma. Surgery, when required in such individuals must be preceded by temporary correction of the clotting abnormality with fresh plasma transfusions, cryoprecipitate or by injections of Factor VIII concentrates. Advantages of the use of concentrates of Factor VIII are the avoidance of hyperproteinaemia, overloading the circulatory system and possible kidney dysfunction resulting from large volume transfusions. Several different concentrations of Factor VIII have been used successfully. These range from Fraction 1 of Cohn to highly purified potent preparations. Dried Human Antihaemophilic Fraction – High Potency Factorate is a purified preparation with lower levels of fibrinogen and other non-AHF protein per international unit than 'Intermediate Purity' AHF preparations.

SYRTUSSAR*

Presentation A red syrupy liquid. Each 5 ml contains:

Dextromethorphan Hydrobromide BP	10 mg
Pheniramine Maleate USNF XII	7.5 mg

Uses Coughs.

Dosage and administration **Adults:** One to two 5 ml spoonfuls three to four times a day.

Children over 6: Half the adult dose three to four times a day.

Children 2–6 years: Half a 5 ml spoonful three times a day.

Note: If required, Syrtussar may be diluted with Syrup BP.

Contra-indications, warnings, etc The preparation may cause drowsiness. If affected, do not drive or operate machinery. Avoid alcoholic drink.

Pharmaceutical precautions Store in a cool place – Shelf life 5 years.

Legal category P.

Package quantities Bottles of 100 ml and 1 litre dispensing pack.

Further information Dextromethorphan hydrobromide is an effective antitussive agent which, combined with antihistamine, provides a therapy for coughs.

Product licence number 0231/5019.

**Trade Mark*

Astra Pharmaceuticals Limited
St Peter's House
2 Bricket Road
St Albans Herts AL1 3JW

ASTRA

BETALOC*

Presentation White tablets containing either 50 mg metoprolol tartrate coded A/BB or 100 mg metoprolol tartrate coded A/ME.

Uses In the management of hypertension and angina pectoris. Cardiac arrhythmias, especially supraventricular tachyarrhythmias. Adjunct to the treatment of thyrotoxicosis.

Dosage and administration The dose must always be adjusted to the individual requirements of the patient. The following are guide lines:

Hypertension: Total daily dose 100–400 mg to be given as a single or twice daily dose.

The starting dose is 100 mg per day. This may be increased by 100 mg per day at weekly intervals.

If full control is not achieved using a single daily dose, a.b.d. regimen should be initiated. Combination therapy with a diuretic or other hypotensive agent may also be considered.

Angina: Usually 50–100 mg twice or three times daily.

Cardiac arrhythmias: 50 mg b.i.d. or t.i.d. should usually control the condition. If necessary the dose can be increased up to 300 mg per day in divided doses.

Following the treatment of an acute arrhythmia with Betaloc injection, continuation therapy with Betaloc tablets should be initiated 4–6 hours later. The initial oral dose should not exceed 50 mg t.i.d.

Thyrotoxicosis: 50 mg four times a day.

Contra-indications, warnings, etc

Contra-indications: A V block. Digitalis refractory heart failure.

Warnings: In labile and insulin-dependent diabetes it may be necessary to adjust the hypoglycaemic therapy.

Betaloc therapy must be reported to the anaesthetist prior to general anaesthesia.

Digitalisation should be considered for patients with a previous history of heart failure, or patients known to have a poor cardiac reserve.

Betaloc has proved safe in a large number of asthmatic patients; although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease.

Until further clinical experience is available, it is recommended that treatment with Betaloc be avoided during pregnancy.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Side-effects: These are mild and have been infrequently reported. The commonest appear to be lassitude, GI disturbances, and disturbance of sleep pattern. In many

cases these effects have been transient, or have disappeared after a reduction in dosage.

Pharmaceutical precautions Protect from light, heat and moisture.

Legal category POM.

Package quantities Securitainers of 100 and 500.

Further information *Treatment of overdose:* Marked bradycardia may be treated by intravenous atropine sulphate (0.25–2.0 mg) and in severe cases by slow intravenous infusion of about 5 mcg per minute of isoprenaline.

Metoprolol undergoes biotransformation in the liver and thereafter is mainly excreted as inactive metabolites by the kidney.

Product licence numbers

Tablets 50 mg 0017/0073

Tablets 100 mg 0017/0074

BETALOC* I.V. INJECTION ▼

Presentation *Ampoules:* Each ampoule of 5 ml contains 5 mg metoprolol tartrate.

Uses Control of tachyarrhythmias, especially supraventricular tachyarrhythmias.

Dosage and administration Initially up to 5 mg injected i.v. at a rate of 1–2 mg per minute. The injection can be repeated at 5 minute intervals until a satisfactory response has been obtained.

A total dose of 10–15 mg generally proves sufficient. Because of the risk of a pronounced drop of blood pressure, the i.v. administration of Betaloc to patients with a systolic blood pressure below 100 mm Hg should only be given with special care.

During anaesthesia: 2–4 mg injected slowly i.v. at induction is usually sufficient to prevent the development of arrhythmias during anaesthesia. The same dosage can also be used to control arrhythmias developing during anaesthesia. Further injections of 2 mg may be given as required to a maximum overall dose of 10 mg.

Contra-indications, warnings, etc

Contra-indications: AV Block. Digitalis refractory heart failure. Severe bradycardia. Cardiogenic shock.

Warnings: In labile and insulin dependent diabetes, it may be necessary to adjust the hypoglycaemic therapy.

Betaloc therapy must be reported to the anaesthetist prior to general anaesthetic.

Digitalisation should be considered for patients with a previous history of heart failure, or patients known to have a poor cardiac reserve.

Betaloc has proved safe in a large number of asthmatic patients; although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. In patients

suffering from asthma, additional therapy with a β_2 -stimulant (e.g. terbutaline) may be advisable.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Betaloc therapy should be avoided during pregnancy. If there are overwhelming clinical reasons for its use during the second or third trimesters, particular attention should be paid to its β -blocking effects (especially bradycardia) in the mother, foetus and neonate.

In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible (e.g. halothane/nitrous oxide).

Side-effects: As in the case of other beta-blockers, a marked fall in blood pressure may sometimes occur following intravenous injection of Betaloc.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities 4 x 5 ml ampoules.

Further information *Treatment of overdose:* Marked bradycardia may be treated by intravenous atropine sulphate (0.25 to 2.0 mg) and in severe cases by slow intravenous infusion of about 5 mcg/minute of isoprenaline.

Betaloc is a cardioselective β_1 -receptor blocker exhibiting no intrinsic sympathomimetic activity. Betaloc injection is suitable for the treatment of cardiac arrhythmias, especially supraventricular tachyarrhythmias. Its use often re-establishes normal sinus rhythm in patients with paroxysmal atrial tachycardia or reduces the ventricular rate. Also where atrial fibrillation or flutter exists it can not only reduce ventricular rate but may also restore sinus rhythm. It also reduces the number of ventricular extrasystoles.

Product licence number 0017/0072.

BETALOC-SA

Presentation White tablets (coded A MD) containing 200 mg metoprolol tartrate Durules (sustained action).

Uses In the management of angina pectoris and hypertension.

Dosage and administration Oral, once daily in the morning. In rare cases two tablets may be indicated.

Administration of Betaloc-SA results in a controlled release of active substance which means that the peak plasma levels are reduced. Compared to Betaloc tablets the absorption phase is prolonged and the duration of effect is extended. The substance is completely absorbed and the maximal beta-blocking effect is reached after about four hours.

These factors may lead to a more convenient dosage and an improved degree of beta₁-selectivity.

The effect on the pulse and blood pressure remain pronounced 24 hours after administration.

Betaloc-SA tablets should be swallowed whole and not broken or chewed.

Metoprolol undergoes bio-transformation in the liver

and thereafter is mainly excreted as inactive metabolites by the kidney.

Contra-indications, warnings, etc

Contra-indications: AV block. Digitalis refractory heart failure.

Warnings: In labile and insulin-dependent diabetes, it may be necessary to adjust the hypoglycaemic therapy.

Betaloc therapy must be reported to the anaesthetist prior to general anaesthetic.

Digitalisation should be considered for patients with a previous history of heart failure or patients known to have a poor cardiac reserve.

Betaloc has proved safe in a large number of asthmatic patients; although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. Use of a beta₂-bronchodilator may be advisable in some asthmatics.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Until further clinical experience is available, it is recommended that treatment with Betaloc-SA be avoided during pregnancy.

Side-effects: These are mild and have been infrequently reported. The commonest appear to be lassitude, GI disturbances and disturbances of sleep pattern. In many cases these effects have been transient, or have disappeared after a reduction in dosage.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Calendar pack of 28 tablets. Securainers of 300 tablets.

Further information *Treatment of overdose:* Marked bradycardia may be treated by intravenous atropine sulphate (0.25–2.0 mg) and in severe cases by slow intravenous infusion of about 5 mcg per minute of isoprenaline.

Product licence number 0017/0093.

BRICANYL* SPACER INHALER BRICANYL* INHALER

Presentation *Bricanyl Spacer inhaler:* Metered aerosol with extended mouthpiece, delivering 0.25 mg terbutaline sulphate per actuation.

Bricanyl inhaler: Metered aerosol delivering 0.25 mg terbutaline sulphate per actuation.

Uses A selective beta₂-adrenergic stimulant recommended for the relief of allergic and intrinsic asthma, chronic bronchitis, emphysema and other bronchopulmonary disorders in which bronchospasm is a complicating factor.

Dosage and administration Bricanyl Spacer inhaler is particularly recommended to enable patients with difficulty coordinating conventional aerosols to derive greater therapeutic benefit.

Adults and children: One or two inhalations as required, with a short interval between each inhalation. Not more

than eight inhalations should be necessary in any 24 hours.

See package insert for simple operating instructions.

Contra-indications, warnings, etc No contra-indications are known. Bricanyl should not be used with non-selective beta-blocking agents, but may be used with agents which selectively block cardiac β_1 -receptors. Care should be taken with patients suffering from myocardial insufficiency or thyrotoxicosis. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Side-effects: The frequency of side-effects is low, and those which have been recorded, e.g. tremor and palpitations, are all characteristic of sympathomimetic amines. Whenever these have occurred, the majority have resolved spontaneously within the first week of treatment.

Precautions: Care should be taken when aminophylline or related compounds are given to patients receiving Bricanyl by injection.

Pharmaceutical precautions None.

Legal category POM.

Package quantities *Bricanyl Spacer Inhaler:* aerosol containing 400 metered doses complete with extended mouth piece.

Bricanyl Inhaler: Aerosol containing 400 metered doses.

Further information Bricanyl is also available as Respirator Solution, Tablets, Syrup, Injection, Expecto-rant and Compound Tablets.

Product licence numbers

Bricanyl Spacer Inhaler 0017/0061
Bricanyl Inhaler 0017/0061

BRICANYL* TABLETS BRICANYL* SYRUP

Presentation *Bricanyl Tablets:* Off-white scored tablet containing terbutaline sulphate 5 mg.

Bricanyl Syrup: Clear aqueous solution containing 0.3 mg terbutaline sulphate per ml.

Uses A bronchodilator recommended for relief of allergic and intrinsic asthma, chronic bronchitis, emphysema and other broncho-pulmonary disorders in which bronchospasm is a complicating factor. Bricanyl Expecto-rant is recommended in these conditions where secretion is a complicating factor.

Dosage and administration

Bricanyl Tablets: Adults: 1 tablet twice a day; or three times a day at eight-hourly intervals.

Children: 7-15 years: $\frac{1}{2}$ tablet twice a day; or three times a day at eight-hourly intervals.

Bricanyl Syrup: Adults: 2-3 $\times$ 5 ml spoonfuls three times a day at eight-hourly intervals.

Children: 7-15 years: 1-2 $\times$ 5 ml spoonfuls three times a day at eight-hourly intervals.

3-7 years: $\frac{1}{2}$ -1 $\times$ 5 ml spoonful three times a day at eight-hourly intervals.

Contra-indications, warnings, etc No contra-indications are known. Bricanyl should not be used with non-selective beta-blocking agents, but may be used

with agents which selectively block cardiac β_1 receptors. Care should be taken with patients suffering from myocardial insufficiency or thyrotoxicosis. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Side-effects: The frequency of side-effects is low, and those which have been recorded, e.g. tremor and palpitations, are all characteristic of sympathomimetic amines. Whenever these have occurred, the majority have been spontaneously reversible within the first week of treatment.

Pharmaceutical precautions No special storage conditions are necessary for any of the Bricanyl preparations. The recommended diluent for Bricanyl Syrup is water.

Legal category POM.

Package quantities *Bricanyl Tablets:* Bottles of 100 and 500 tablets.

Bricanyl Syrup: Bottles of 300 ml and 1 litre.

Further information When Bricanyl is prescribed orally a suitable regime for providing eight-hourly administration is: on rising, in the mid-afternoon, on retiring.

Product licence numbers

Bricanyl Tablets 0017/0047
Bricanyl Syrup 0017/0058

BRICANYL* INJECTION

Presentation Clear aqueous solution for injection containing 0.5 mg terbutaline sulphate per ml.

Uses

1. *For bronchodilatation.* A selective β_2 adrenergic stimulant recommended for the relief of allergic and intrinsic asthma, chronic bronchitis, emphysema and other broncho-pulmonary disorders in which bronchospasm is a complicating factor.

2. *For the management of uncomplicated premature labour.*

Dosage and administration

1. *For bronchodilatation.* When a rapid therapeutic response is required, Bricanyl can be administered by any of the three standard parenteral routes: subcutaneous, intramuscular, or i.v. bolus. The preferred routes will usually be subcutaneous or intramuscular. When given as an i.v. bolus the injection must be made slowly noting patient response.

Adults: $\frac{1}{2}$ -1 ampoule (0.25-0.5 mg) up to four times a day.

Children: 2-15 years. 0.01 mg/kg body weight to a maximum of 0.3 mg total.

Age	Average weight		mg terbutaline	ml volume
	kg	(lb)		
<3	10	(22)	0.1	0.2
3	15	(33)	0.15	0.3
6	20	(44)	0.2	0.4
8	25	(55)	0.25	0.5
10+	30+	(66+)	0.3	0.6

By infusion: 3 to 5 ampoules (1.5–2.5 mg) in 500 ml dextrose, saline or dextrose/saline solution given by continuous intravenous infusion at a rate of 10–20 drops (0.5–1 ml) per minute for 8 to 10 hours. Corresponding reduction in dosage should be made for children.

2. For management of premature labour. The dose must be individually titrated with reference to suppression of contractions, increase in pulse rate and changes in blood pressure, which are limiting factors.

These parameters should be carefully monitored during treatment. A maternal heart rate of more than 135 beats/min should be avoided. 10 mcg/min i.v. should be infused during the first hour. This can be increased by 5 mcg/min at 10 min intervals until the contractions stop. The highest dose should be 25 mcg/min. During the next seven hours, the dose should be decreased in 30 minute periods by 5 mcg/min to the lowest maintenance dose that produces continued suppression of the contractions. After this initial treatment, subcutaneous injections (0.25 mg) should be given four times a day for three days. During this period, oral treatment should be started (5 mg three times a day). The oral treatment should be continued until the end of the 36th week of pregnancy. Suggestion for dilution: 5 mg (10 ampoules) in 1,000 ml of dextrose solution (40 drops contain approximately 10 mcg).

Contra-indications, warnings, etc

1. For bronchodilatation. No contra-indications are known. Bricanyl should not be used with non-selective beta-blocking agents, but may be used with agents which selectively block cardiac receptors. Care should be taken with patients suffering from myocardial insufficiency or thyrotoxicosis. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Side-effects: When used as a bronchodilator the frequency of side-effects is low, and those which have been recorded, e.g. tremor and palpitations, are all characteristic of sympathomimetic amines. Whenever these have occurred, the majority have resolved spontaneously within the first week of treatment.

Precautions: When used for bronchodilatation care should be taken when aminophylline or related compounds are given to patients receiving Bricanyl by injection.

2. For management of premature labour. The following are contra-indications: ante-partum haemorrhage due to any cause, toxæmia of pregnancy, cord compression. Any condition of the mother or foetus in which prolongation of pregnancy is hazardous.

In premature labour in a patient with known or suspected cardiac disease a physician experienced in cardiology should assess the suitability of treatment before i.v. infusion with Bricanyl.

Warnings: In treatment of premature labour, hyperglycaemia and ketoacidosis have been found in pregnant women with diabetes after treatment with β_2 -stimulants. It may therefore be necessary to adjust the insulin dose when β_2 -stimulants are used in the treatment.

During infusion treatment in pregnant women with β_2 -stimulants in combination with corticosteroids a rare complication with a pathological picture resembling pulmonary oedema, has been reported.

Increased tendency to uterine bleeding has been reported in connection with Caesarian section. However,

this can be effectively stopped by propranolol 1–2 mg injected intravenously.

Pharmaceutical precautions No special storage conditions are necessary. The recommended diluent is water for injection, or sterile saline or dextrose.

Legal category POM.

Package quantities Packs of 5 × 1 ml ampoules.

Further information Nil.

Product licence number 0017/0048.

BRICANYL* COMPOUND TABLETS BRICANYL* EXPECTORANT

Presentation *Compound Tablets:* Plain white tablets each containing:

Terbutaline sulphate	2.5 mg
Guaiphenesin	100 mg

Expectorant: Clear aqueous solution containing:

Terbutaline sulphate	0.3 mg/ml
Guaiphenesin	13.3 mg/ml

Uses Bronchodilator and expectorant recommended for relief of bronchial asthma, bronchitis, emphysema and other broncho-pulmonary disorders where bronchospasm and secretion are complicating factors.

Dosage and administration *Compound Tablets:* Two tablets three times daily at eight-hourly intervals. Not recommended for children.

Expectorant: *Adults:* 2–3 × 5 ml spoonfuls three times daily at eight-hourly intervals. Not recommended for children.

Contra-indications, warnings, etc No contra-indications are known. Bricanyl should not be used with non-selective beta-blocking agents, but may be used with agents which selectively block cardiac β_1 receptors. Care should be taken with patients suffering from myocardial insufficiency or thyrotoxicosis. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Side-effects: The frequency of side-effects is low. Those which have been recorded, e.g. tremor and palpitations, are all characteristic of sympathomimetic amines. Whenever these have occurred, the majority have been spontaneously reversible within the first week of treatment.

Pharmaceutical precautions No special storage conditions required. Recommended diluent for expectorant is water.

Legal category POM.

Package quantities *Compound Tablets:* Bottles of 100.

Expectorant: Bottles of 300 ml and 1 litre.

Further information Bricanyl is also available as ampoules, plain tablets, syrup, pressurised aerosol and respirator solution.

Product licence numbers

Expectorant	0017/0068

BRICANYL[®] RESPIRATOR SOLUTION

Presentation A solution containing 10 mg/ml terbutaline sulphate.

Uses For the relief of severe bronchospasm.

Dosage and administration *Adults:* The usual dose of terbutaline by wet aerosol is 2–5 mg or in severe cases up to 10 mg. Administration of terbutaline solution can be via a nebuliser or an IPPV machine.

The terbutaline solution must be diluted with sterile physiological saline to ensure delivery of the correct dose. Such dilution will depend on two factors: the period of time over which the dose of terbutaline is to be delivered; the design of the equipment used to deliver the solution – its capacity, dead-space, etc.

For example, administration over a short period of time in a machine capable of completely utilising small volumes of liquid (e.g. Bird Respirator) may indicate little if any dilution (e.g. 3–5 ml). At the other extreme, use of a nebuliser such as Ventimask, Wright's or De Vilbiss would require a dilution suited to the equipment and administration time. For such chronic administration terbutaline should be given at a rate of 1–2 mg per hour in a solution of 100 mcg/ml (1 : 100 dilution).

Children: The doses in the table below are based on the adult dosage for severe bronchospasm of 10 mg terbutaline.

Acute usage: table below based on adult dosage for severe bronchospasm of 10 mg terbutaline.

Age	Average weight		mg terbutaline	ml undiluted solution
	kg	lb		
<3	10	22	2.0	0.2
3	15	33	3.0	0.3
6	20	44	4.0	0.4
8	25	55	5.0	0.5
10+	30+	66+	6.0	0.6

Chronic usage: Pro rata to adult chronic administration.

Contra-indications, warnings, etc No contra-indications are known. Bricanyl should not be used with non-selective beta-blocking agents, but may be used with agents which selectively block cardiac β_1 receptors. Care should be taken with patients suffering from myocardial insufficiency or thyrotoxicosis. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Side-effects: The frequency of side-effects is low and those which have been recorded, e.g. tremor and palpitations, are all characteristic of sympathomimetic amines. Whenever these have occurred, the majority have been spontaneously reversible within the first week of treatment.

Pharmaceutical precautions Bricanyl Respirator solution should be stored in a cool place away from light.

Whilst the usual diluent will be sterile physiological saline, water for injection can also be used.

Solution in nebulisers should be replaced daily.

Legal category POM.

Package quantities 10 ml.

Further information Nil.

Product licence number 0017/0078

BRICANYL[®] SA

Presentation White tablet with engraving ^A_{BD} containing 7.5 mg terbutaline sulphate in a sustained-release formulation.

Uses For relief of bronchospasm in bronchial asthma and in chronic bronchitis, emphysema and other pulmonary disorders in which bronchospasm is a complicating factor.

Dosage and administration *Adults:* 1 tablet morning and evening. The tablet may not be divided or chewed, but must be swallowed whole together with liquid.

Contra-indications, warnings, etc Bricanyl should not be used with non-selective β -blocking agents. (Non-selective β -blockers can completely or to some extent nullify the effect of β -receptor stimulants) but may be used with agents which selectively block cardiac β_1 -receptors. Care should be taken with patients suffering from myocardial insufficiency, thyrotoxicosis and diabetes. Bricanyl is contra-indicated when there is known hypersensitivity to sympathomimetic amines.

Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy. It is not known if terbutaline sulphate passes over to maternal milk.

Side-effects: The frequency of side effects is low and those which have been recorded, e.g. tremor and palpitations are all characteristic of sympathomimetic amines. Whenever these have occurred the majority have been spontaneously reversible within the first week of treatment.

As with other β -stimulants cramps may occur in hands and feet at high dosage.

Pharmaceutical precautions No special storage conditions are necessary.

Legal category POM.

Package quantities Glass bottles containing 60 tablets.

Further information The inactive components in Bricanyl SA form a matrix which is insoluble in the digestive juices. The empty matrix may sometimes pass through the digestive system unchanged and be excreted.

Product licence number 0017/0110

CITANEST[®]

Presentation Sterile clear aqueous solution for local anaesthesia. Each ml contains:

0.5% solution: Prilocaine hydrochloride 5 mg.

1% solution: Prilocaine hydrochloride 10 mg.

Uses Infiltration anaesthesia, nerve blocks, intravenous regional blocks, analgesia.

Dosage and administration Basically it should be remembered that the smallest dose to produce the required effect should be given. The maximum adult dose (body weight 70 kg) should not exceed 400 mg; for children and debilitated patients smaller amounts and weaker concentrations directly proportionate to weight are indicated.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Adverse reactions: Systemic effects are practically unknown due to the small dosages employed. However, at the recommended maximum dosage there is a transient increase of the methaemoglobin value, sometimes with a concomitant cyanosis. If considered desirable intravenous methylene blue treatment (1 mg/kg body weight) may be instituted.

If toxic reactions occur as a result of overdosage, faulty injection technique or possible hypersensitivity, treatment is the same as for other local anaesthetics. The type of toxic reaction is unpredictable, and depends on dosage, route of administration and state of the patient. Reactions are primarily of two types typified by stimulation and depression of the cerebral cortex and medulla respectively.

Precautions: Care should be observed in patients suffering from epilepsy.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities 0.5% and 1% solution: Vials of 20 ml and 50 ml.

Further information Citanest multidose vials contain methylhydroxybenzoate 1 mg/ml.

Product licence numbers

0.5% 0017/5047

1% 0017/5048

CITANEST* 3% WITH ADRENALINE 1 : 300,000

Presentation Sterile clear aqueous solution for dental anaesthesia: prilocaine hydrochloride 30 mg/ml, Adrenaline BP 1 : 300,000.

Uses For dental infiltration anaesthesia where there is no necessity for profound ischaemia in the area injected. For all dental nerve-block techniques.

Dosage and administration Infiltration – 1 ml. Nerve block – 1.5–2 ml.

The recommended maximum dosage is higher than that recommended for a plain solution, but total dosage should not exceed 600 mg in a healthy adult of body weight 70 kg. The total dose should not exceed 20 ml. In children, aged and debilitated patients the dose may be reduced and calculated in relation to body weight.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Precautions: All established precautions on the use of adrenaline should be observed, e.g. cardiac patients, hypertension, thyrotoxicosis, in patients taking tricyclic antidepressants. If toxic reactions occur as a result of overdosage, faulty injection technique or possible hypersensitivity, treatment is the same as for other local anaesthetics. Care should be observed in patients suffering from epilepsy.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Glass cartridges of 2 ml in boxes of 100.

Further information Citanest 3% with adrenaline

1 : 300,000 solutions contain methylhydroxybenzoate 1 mg/ml.

Product licence number 0017/5002.

CITANEST* 3% WITH OCTAPRESSIN*

Presentation Sterile clear aqueous solution for dental anaesthesia: prilocaine hydrochloride 30 mg/ml, felypressin 0.03 i.u. per ml.

Uses Local anaesthetic solution with vasoconstrictor for dental infiltration anaesthesia where there is no necessity for profound ischaemia in the area injected. For all dental nerve-block techniques.

Dosage and administration 1–2 ml should be sufficient for the majority of procedures. The addition of Octapressin decreases the rate of absorption of the injected solution. For this reason the recommended maximum dosage for Citanest with Octapressin is higher than that recommended for a plain solution, but total dosage of Citanest should not exceed 600 mg in a healthy adult of body weight 70 kg. The total dose should not exceed 20 ml. In aged and debilitated patients the dose must be reduced. In children the maximum dose is considerably less and should be calculated in relation to body weight.

Contra-indications, warnings, etc In known cases of ischaemic heart disease not more than four cartridges should be used at one sitting.

Known sensitivity to local anaesthetics of the amide type.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage, route of administration and state of the patient. The reactions are primarily of two types, and typified by stimulation and depression of the cerebral cortex and medulla respectively. Slow onset – stimulation leading to nervousness, dizziness, blurred vision, nausea, tremors, convulsions and respiratory arrest. Rapid onset – depression leading to respiratory arrest, cardiovascular collapse and cardiac arrest. Symptoms occur rapidly and with little warning.

Precautions: Adequate resuscitation equipment must be available whenever local or general anaesthesia is administered. Though clinical tolerance is remarkably good, overdosage or accidental intravenous injection may give rise to toxic reactions. Care should be observed in patients suffering from epilepsy.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Glass cartridges of 2 ml standard, and 2 ml self-aspirating, in boxes of 100.

Further information Citanest 3% with Octapressin solutions contain methylhydroxybenzoate 1 mg/ml.

Product licence number 0017/5003.

CITANEST* 4%

Presentation Sterile clear aqueous solution. Each millilitre contains prilocaine hydrochloride 40 mg.

Uses Local anaesthetic solution without vasoconstrictor for dental infiltration anaesthesia where there is no necessity for profound ischaemia in the area injected.

For all dental nerve-block techniques. For all dental injections where a vasoconstrictor is contra-indicated.

Dosage and administration 1–2 ml. In a healthy adult of a normal body weight (70 kg) the maximum dose should not exceed 400 mg. In aged and debilitated patients the dose must be reduced, and in children the maximum dose should be calculated in relation to body weight, i.e. 3 mg per lb or 6 mg per kg.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Side-effects: Systemic effects due to the use of Citanest in dental practice are practically unknown due to the small dosages employed.

Adverse reactions: The type of toxic reaction is unpredictable, and depends on dosage, route of administration and state of patient. Reactions are primarily of two types typified by stimulation and depression of the cerebral cortex and medulla respectively.

Precautions: Though clinical tolerance is remarkably good, overdosage or accidental intravenous injection may give rise to toxic reactions. These are best avoided by aspiration before making an injection, in order to avoid accidental intravascular injection. Care should be observed in patients suffering from epilepsy.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Glass cartridges of 2 ml standard and 2 ml self-aspirating in boxes of 100.

Further information Citanest 4% solutions contain methylhydroxybenzoate 1 mg/ml.

Product licence number 0017/5050.

CO-BETALOC*

Presentation White scored tablets (coded A/MH) containing 100 mg metoprolol tartrate and 12.5 mg hydrochlorothiazide.

Uses In the management of mild or moderate hypertension. The combination product may be suitable for use when satisfactory control of arterial blood pressure cannot be obtained with either a diuretic or a beta-adrenoceptor blocking drug used alone.

Dosage and administration The dose will depend on patient response. Usually 1–3 tablets per day as a single or in divided dose.

Contra-indications, warnings, etc

Contra-indications: AV block.

Digitalis refractory heart failure.

Severe kidney and liver failure.

Manifest gout.

Anti-diuretic effect has been reported following concomitant treatment with diuretics and lithium. As with all products which contain diuretics, Co-Betaloc is contra-indicated during lithium therapy.

Warnings: In labile and insulin dependent diabetes, it may be necessary to adjust the hypoglycaemic therapy.

Co-Betaloc therapy must be reported to the anaesthetist prior to general anaesthesia.

Digitalisation should be considered for patients with a previous history of heart failure, or patients known to have a poor cardiac reserve.

Metoprolol has proved safe in a large number of asthmatic patients; although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Until further evidence is available Co-Betaloc therapy should be avoided in pregnancy.

Side-effects: Are mild and infrequent. The most common are gastro-intestinal disturbance, lassitude and disturbances of sleep pattern. In many cases these effects are transient or have disappeared with a reduction in dosage. The familiar side-effects of thiazide diuretics may be expected.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Calendar packs of 28 tablets. Securitainers of 300 tablets.

Further information The use of a selective beta-blocker in this combination may counteract the tendency to hyperglycaemia which the diuretic may provoke.

Treatment of overdosage: Marked bradycardia may be treated by intravenous atropine sulphate (0.25–2.0 mg) and in severe cases by slow intravenous infusion of about 5 mcg per minute of isoprenaline.

Product licence number 0017/0092.

DIRYTHMIN SA* ▼

Presentation White, film-coated sustained release tablets (Durules), engraved $\text{D}_\text{A}_\text{R}$ on one side containing 150 mg disopyramide base as the phosphate.

Uses Dyrhythm-SA is a Class I antiarrhythmic drug, indicated for treatment of a wide range of supraventricular and ventricular arrhythmias including:

Atrial or ventricular ectopic beats.

Paroxysmal atrial or ventricular tachycardia.

Arrhythmias associated with myocardial infarction.

Wolff-Parkinson-White syndrome.

Maintenance of sinus rhythm following electro-conversion.

Dyrhythm-SA can be used in both digitalised and non-digitalised patients.

Dosage and administration The dosage should be adjusted dependant on the patient response and tolerance. The normal adult dosage is 2 tablets 12 hourly (600 mg daily). Dosage should not normally exceed 900 mg daily.

In patients with moderate renal insufficiency (creatinine clearance > 40 ml/min) or hepatic insufficiency, dosage should be limited to 1 Dyrhythm-SA tablet b.d. In patients with creatinine clearance < 40 ml/min standard capsules are advised.

Dyrhythm-SA tablets should be swallowed whole.

Patients treated with conventional disopyramide capsules q.i.d. can be transferred to the equivalent dosage

of Dirythmin-SA e.g. 150 mg disopyramide q.i.d. is equivalent to 2 × 150 mg Dirythmin-SA tablets b.d.

Contra-indications, warnings, etc

Contra-indications: AV block II and III in absence of pacemaker. Known hypersensitivity. Cardiogenic shock.

Warnings: Disopyramide should not be administered to patients with cardiomyopathy, or uncompensated cardiac failure.

Treatment with disopyramide should be discontinued if any of the following develop: Hypotension, 2nd or 3rd degree heart block, significant QRS prolongation (> 25%) or QT prolongation.

Disopyramide has been associated with hypoglycaemia usually in patients with impaired liver function. Caution should be observed in patients with prostatic hypertrophy, glaucoma, myasthenia gravis or digitalis intoxication.

Disopyramide dosage should be reduced if 1st degree heart block develops and may require discontinuation if the block persists.

Patients should be digitalised prior to administration of disopyramide for the treatment of atrial flutter or fibrillation or blocked SVT.

Use of disopyramide with other Class I antiarrhythmics and/or beta-blockers is not recommended.

Disopyramide may be ineffective in the presence of marked hypokalaemia.

The safety and efficacy of disopyramide in children has not been established. The safety of disopyramide in pregnancy has not been established.

Side-effects: Side-effects reported are usually associated with the anticholinergic properties of disopyramide and include dry mouth, blurred vision and urinary retention.

Treatment of overdosage: Disopyramide should be discontinued and supportive or symptomatic treatment instigated.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Amber glass bottles of 100 tablets.

Further information Nil.

Product licence number 0017/0100.

HEMINEVRIN* 0.8% INFUSION

Presentation Colourless aqueous solution; chlormethiazole edisylate 8 mg/ml.

Uses Hypnotic and anticonvulsant for the treatment of pre-eclamptic toxemia, status epilepticus, acute alcohol withdrawal symptoms and delirium tremens.

Dosage and administration *Pre-eclamptic toxemia:* An intravenous infusion is set up with 30–50 ml Heminevrin 0.8%. The solution is run in quickly at 60 drops per minute (4 ml/min) until the patient feels drowsy. The exact amount given depends on the patient's response. The drip rate is then maintained at 15 drops/minute (= 1 ml/minute) or decreased to 10 drops per minute if the patient is very drowsy. As the patient responds very quickly to the change of dosage, the drip rate can be increased if the patient is restless, and reduced again once the patient is well sedated.

Status epilepticus: 40–100 ml of Heminevrin 0.8% infusion administered over a period of 5–10 minutes will usually stop convulsions. Thereafter an intravenous infusion of Heminevrin 0.8% may be required depending on the patient's response.

Acute alcohol withdrawal symptoms and delirium tremens: Either of the above regimes can be utilised depending on the patient's condition but if the rapid infusion method is used it will be necessary to continue with either an infusion of Heminevrin 0.8% or oral therapy with Heminevrin capsules due to the short half life (three to four hours) of chlormethiazole.

Contra-indications, warnings, etc *Side-effects:*

Heminevrin has a very low toxicity. The most common side-effect appears to be a tingling sensation in the nose and sneezing, occurring immediately after the start of the intravenous infusion. Conjunctival irritation has also been noted in some cases, and occasionally these symptoms may be severe and may be associated with severe headache. Intravenous administration of Heminevrin solution may be followed by a slight but temporary decrease in blood pressure, which is less pronounced the slower the infusion is given. Local reactions such as thrombophlebitis at the site of injection are exceedingly rare, except when using the continuous intravenous infusion. In these cases superficial phlebitis has been frequently reported, but only of a mild degree. Neither heparin nor cortisone has been shown to be helpful in preventing such reactions.

Precautions: Heminevrin may potentiate or be potentiated by centrally acting depressant drugs, including alcohol, thus when used concomitantly dosages should be appropriately reduced. The patient should be kept under close and constant observation by a nurse during the period of continuous drip infusion. With too high a rate of infusion the sleep induced with Heminevrin can pass unnoticed into deep unconsciousness with the consequent risk of mechanical airway obstruction. With gross overdosage there is always the possibility of causing centrally induced respiratory depression and circulatory collapse. In view of the possible risk of slight respiratory depression during routine Heminevrin intravenous therapy, caution should be observed when administering the solution to patients with a history of obstructive pulmonary disease. Because of the possible danger of mechanical airway obstruction occurring in deep sleep during Heminevrin therapy, the patient should be maintained where necessary by the use of an oral airway tube. In addition, an aspirator should always be close at hand.

Pharmaceutical precautions To be stored within the temperature range 5°C–8°C.

Legal category POM.

Package quantities Bottles of 500 ml.

Further information Nil.

Product licence number 0017/5007.

**HEMINEVRIN* CAPSULES
HEMINEVRIN* SYRUP**

Presentation *Capsules:* Off-white oval capsule containing chlormethiazole (base) 192 mg in arachis oil.

Syrup: Clear, colourless, aqueous solution containing chlormethiazole edisylate 50 mg/ml.

Uses Neuropharmacological studies in animals show that Heminevrin possesses sedative/hypnotic and anti-convulsant properties. Whilst the mode of action is uncertain, the anticonvulsant effect may involve direct or indirect actions on GABA-systems in the CNS. The sedative/hypnotic properties involve actions on both catecholaminergic and gabaergic systems.

Indications: In adults, Heminevrin is indicated in the management of restlessness and agitation in the elderly, in the short term treatment of insomnia in the elderly and in the control of symptoms arising from acute withdrawal from alcohol where close hospital supervision is also provided.

Heminevrin is not recommended for use in children.

Dosage and administration *Sleep disturbances in the elderly:* The usual dose will be two capsules or two 5 ml spoonful of syrup before going to bed. In rare cases, one capsule of 5 ml syrup will suffice.

Management of restlessness and anxiety: One capsule or 5 ml syrup three times daily.

Alcohol withdrawal states: Heminevrin is not a treatment for 'alcoholism'. Alcohol withdrawal should be treated in hospital or, in exceptional circumstances, on an out-patient basis by specialist units when the daily dosage of Heminevrin must be monitored closely by community health staff. The dosage should be adjusted to patient response. A suggested regimen is:

Initial dose: 2 to 4 capsules, if necessary repeated after some hours.

Day 1, first 24 hours: 9 to 12 capsules, divided into 3 or 4 doses.

Day 2: 6 to 8 capsules, divided into 3 or 4 doses.

Day 3: 4 to 6 capsules, divided into 3 or 4 doses.

Days 4 to 6: A gradual reduction in dosage until final dose.

Administration for more than nine (9) days is not recommended. 5 ml of Heminevrin syrup can be substituted for each capsule administered, if desired.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to chlormethiazole. Acute pulmonary insufficiency.

Precautions: Chronic pulmonary insufficiency. Chronic renal or hepatic disease. Heminevrin may potentiate or be potentiated by centrally acting depressant drugs including alcohol. Whilst the concurrent use of other central nervous system drugs should be avoided, if they are used, dosages should be appropriately reduced. Particular caution should be exercised when either chlormethiazole or another CNS depressant is given parenterally. Hypoxia, resulting from, for example, cardiac and/or respiratory insufficiency, may result in manifestations of symptoms of agitation and restlessness leading to a confusional state. Recognition and specific treatment of the cause is essential in such patients.

Warnings and adverse effects: The most common side-effect is nasal congestion and irritation, which may occur 15 to 20 minutes after drug ingestion. Conjunctival irritation has also been noted in some cases and, occasionally, these symptoms may be severe and may be associated with severe headache. Gastrointestinal disturbances have been reported.

Hangover effects in the elderly are uncommon but may occur.

Excessive sedation may occur, especially with higher

doses or when given to the elderly for daytime sedation. Paradoxical excitement or confusion may occur rarely. Large doses of chlormethiazole depress respiration. Performance at skilled tasks and alertness may be impaired.

Where relevant, patients should be warned of this hazard and advised not to drive or operate machinery during treatment.

When Heminevrin has been given at higher than recommended doses for other than recommended indications over prolonged periods of time, physical dependence, tolerance and withdrawal reactions have been reported.

Great caution is required in prescribing Heminevrin for patients with a history of chronic alcoholism, drug abuse or marked personality disorder.

Heminevrin should not be prescribed for alcoholics who continue to drink alcohol.

Overdose: The main symptoms to be expected with overdose of Heminevrin are: coma, respiratory depression, hypotension and hypothermia.

Hypothermia is thought to be due to a direct central effect as well as a result of lying unconscious for several hours. In addition, patients have increased secretion in the upper airways, which in one series was associated with a high incidence of pneumonia. The effects of overdosage are not usually severe in patients with no evidence of alcoholic liver disease, but they may be exacerbated when chlormethiazole is taken in combination with alcohol and/or CNS depressant drugs, particularly those that are metabolised by the liver. There is no specific antidote to chlormethiazole. Treatment of overdosage should therefore be carried out on a symptomatic basis, applying similar principles to those used in the treatment of barbiturate overdosage.

Further information Heminevrin has a short half life and therefore a low incidence of daytime sedation when prescribed as an hypnotic.

In the elderly, the safety and efficacy of Heminevrin has been established in controlled studies of up to three months duration. However, as with all psychotropic drugs, treatment should be kept to a minimum, reviewed regularly and discontinued as soon as possible.

Pharmaceutical precautions Nil.

HEWLETT'S* ANTISEPTIC CREAM

Presentation White scented cream: zinc oxide 8%, boric acid 2.5%, lanolin 4%.

Uses Topical ointment for nursing hygiene and care of skin.

Dosage and administration Applied as required.

Contra-indications, warnings, etc Not to be administered to large areas of broken skin.

Pharmaceutical precautions Store at room temperature.

Legal category P.

Package quantities 35 g tubes.

Further information Nil.

Product licence number 0017/5010.

HYPRENAN* ▼

Presentation A clear, colourless solution containing 1 mg per ml prenalterol hydrochloride in 5 ml ampoules.

Uses Hyprenan is indicated only in adults who require inotropic support in the treatment of heart failure associated with myocardial infarction, open heart surgery or shock, and for the reduction or abolition of the cardiac effects of beta-adrenoceptor blockade.

Dosage and administration 1. When inotropic support is required in the treatment of heart failure associated with myocardial infarction, open heart surgery or shock, Hyprenan should be given by slow intravenous infusion, at a rate of 0.5 mg per minute. However, the rate of the administration and duration of therapy should be adjusted according to patient response as determined by heart rate, blood pressure and, if possible, cardiac output. The maximum total dose used in clinical trials has been 20 mg.

2. To abolish or reduce the cardiac effects of beta-adrenoceptor blockade, Hyprenan should be given in doses of 2–5 mg i.v. Hyprenan should be administered cautiously, generally over a 5 minute period depending on the acuteness of the situation. The optimal effect of each dose is generally achieved within 2–5 minutes, after which further doses may be given to a maximum of 20 mg total. Larger doses of Hyprenan may be necessary in patients who have taken beta-adrenoceptor blocking agents in excess of the recommended dose.

Contra-indications, warnings, etc Hyprenan should not be given to patients with serious ventricular arrhythmias.

Pregnacy: Toxicology studies in animals have indicated an increased occurrence of undesirable effects on foetal development, manifest as abnormalities of the thoracic cage and cardiovascular system. The significance of this in man is, however, uncertain. Nevertheless, benefit: risk should be considered before administering prenalterol to pregnant women or women of child-bearing age.

Caution: Hypovolaemia should be corrected before giving Hyprenan. Hyprenan should be used with caution in patients with angina pectoris and recent myocardial infarction (during the first 6 weeks post infarction). Hyprenan should be used with caution in patients with hypokalaemia. Patients with uncontrolled or insulin-dependent diabetes should be kept under careful observation. Hyprenan should be used with great caution in patients with obstructive subvalvular cardiomyopathy as inotropic agents may exacerbate the obstruction to flow in these patients. If excessive increase in blood pressure or heart rate occurs and it is desired to counteract the effects of Hyprenan, a beta-adrenoceptor blocking agent should be given intravenously.

Side-effects: Palpitations and nervousness may occur. Isolated ventricular ectopic beats have been observed. In some patients with a history of angina pectoris, Hyprenan has caused an increase in anginal attacks.

Pharmaceutical precautions Recommended di-

luents are: sterile saline, Ringer's or 5% anhydrous glucose solution.

Legal category POM.

Package quantities 4 × 5 ml ampoules.

Further information Hyprenan has a more pronounced effect on cardiac contractility than on heart rate. Cardiac output increases mainly as a result of increased stroke volume. Hyprenan increases the systolic blood pressure with little or no effect on diastolic blood pressure. The plasma half life is about 2 hours. Excretion is mainly via the kidneys with 60% of the dose recoverable from the urine as unchanged drug.

Product licence number 0017/0109

JECTOFR*

Presentation Dark brown liquid for intramuscular injection; Iron Sorbitol Citric Acid Complex BP (50 mg elemental iron per ml).

Uses For the treatment of iron-deficiency anaemia and the rapid replenishment of iron stores.

Dosage and administration The recommended single dose of Jectofer is 1.5 mg per kg body weight by intramuscular injection to a maximum of 100 mg per injection. A series of daily injections of this single dose should be given to restore haemoglobin levels to normal and replenish iron stores based on the following table.

Hb gm/100 ml	5.0	6.0	7.0	8.0	9.0	10.0	11.0
Hb%	33	40	46	53	60	66	73
No. of injections	24	22	20	17	14	12	10

In patients who have a low tolerance threshold to intramuscular iron the injections should be given on alternate days. Not recommended in children under 3 kg (7 lb) body weight.

Contra-indications, warnings, etc Serious liver or kidney damage. Ineffective in aplastic or hypoplastic anaemias and acute leukaemia.

Side-effects: A few cases have been reported of serious reactions of a cardiovascular type with cardiac arrhythmia.

Precautions: The importance of using the correct recommended dose in relation to body weight is emphasised, especially in patients who are already markedly underweight. Oral Iron should be discontinued 24 hours before Jectofer is administered.

Pharmaceutical precautions Store at room temperature, do not refrigerate.

Legal category POM.

Package quantities 10 × 2 ml and 100 × 2 ml ampoules for intramuscular use.

Further information Nil.

Product licence number 0017/5011.

KINIDIN DURULES*

Presentation Film-coated white oval tablets. Each Durule contains 250 mg quinidine bisulphate (equivalent to 200 mg Quinidine Sulphate BP) in a sustained action form.

Uses Maintenance of sinus rhythm following electrical conversion of atrial fibrillation, extrasystoles (atrial, nodal, ventricular), paroxysmal atrial tachycardia, nodal tachycardia, atrial fibrillation, atrial flutter, ventricular paroxysmal tachycardia. Conversion of atrial fibrillation.

Dosage and administration Two to five Durules twice a day (morning and evening). In certain cases, e.g. conversion of atrial fibrillation, it may be necessary to increase this dosage. Should be swallowed whole.

Contra-indications, warnings, etc The presence of acute infections or toxic conditions, known hypersensitivity to quinidine, bundle branch block, untreated cardiac insufficiency, thrombocytopenia.

Side-effects: originating from CNS, termed as cinchonism (impaired hearing, blurred vision, headache, dizziness and vomiting). These symptoms are associated with overdosage and usually disappear on reduction of dosage. Gastro-intestinal irritation resulting in nausea, vomiting.

Adverse reactions: Hypersensitivity reactions are very rare and are manifested as urticaria, increased temperature, which may result in thrombocytopenia. Granulomatous hepatitis with raised liver enzymes, reversible on stopping therapy, has also been reported. Heart block, premature beats, ventricular tachycardia, ventricular fibrillation can occur and are usually a result of overdosage.

Precautions: A test dose of one Kinidin Durule should always be given in order to ascertain whether there is hypersensitivity. In digitalised patients quinidine may increase the concentration of digitalis in plasma by up to 100%. It may therefore be necessary to reduce the dose of digitalis in these patients.

Pharmaceutical precautions Not to be dispensed in a metal container.

Legal category POM.

Package quantities Bottles of 100 and 250.

Further information Nil.

Product licence number 0017/5015.

PROCAINAMIDE DURULES*

Presentation Slightly yellow, circular, convex tablets containing 500 mg procainamide hydrochloride.

Uses Supraventricular tachyarrhythmias (atrial premature beats, paroxysmal atrial tachycardia, atrial flutter, atrial fibrillation, AV junctional tachycardia and premature beats).

Ventricular arrhythmias (ectopic beats, premature beats, and tachycardia).

Digitalis induced arrhythmias.

Dystrophia myotonica; myotonica congenita (Thomsen).

Dosage and administration Ideally the dosage should be adjusted to maintain a serum concentration between 4–8 mcg per ml, usually 2–3 tablets three times a day (3–4.5 g daily).

Guidelines: Anti-arrhythmic prophylaxis after acute myocardial infarction, initially 3–4 Durules followed by 2–3 Durules thrice daily as maintenance. During transition from lignocaine therapy, treatment with Procainamide Durules should be initiated two hours prior to

discontinuation of infusion of lignocaine. It may occasionally be necessary to divide the daily dose into 4 doses per day.

The Durules should be swallowed whole, not broken or chewed.

Contra-indications, warnings, etc

Contra-indications: Procainamide hypersensitivity. Second or third degree AV-block and bifascicular block with AV-block type I if the patient does not have a pacemaker. Bronchial asthma, myasthenia gravis and SLE are relative contra-indications.

Precautions: In patients with renal insufficiency or heart failure, accumulation of procainamide may occur; caution should therefore be observed and the dose adjusted if necessary. Accumulation leads to an impairment of hepatic and/or renal function.

Side-effects: Procainamide is generally well tolerated, but anorexia, nausea and vomiting and diarrhoea may occur. Occasional cases of flushing, skin rash, pruritis, depression, vertigo, psychosis with hallucinations, shivering, fever, joint and muscle pain, 'bitter taste' and muscle weakness have been reported. A possible lupus erythematosus-like syndrome may occur during treatment. Serological tests for ANF should therefore be made before commencement of treatment and regularly thereafter. The blood should also be examined for LE-type cells at the same time. If the ANF titre rises or LE cells appear, then cessation of treatment should be considered. Usually these increases are noted before overt clinical symptoms are detectable. The syndrome is usually completely reversible. Serious side-effects in the form of leucopenia and agranulocytosis may occur during long-term treatment.

Pharmaceutical precautions Procainamide Durules may be stored at room temperature.

Legal category POM.

Package quantities 500 mg tablets in bottles of 100.

Further information Procainamide Durules are a sustained release formulation which enable therapeutic blood levels of procainamide to be conveniently attained and maintained.

Product licence number 0017/0071.

TONOCARD* ▼

Presentation Yellow, biconvex, film coated tablets containing tocainide hydrochloride, either 400 mg (coded A/TT) or 600 mg (coded A/TC).

Injection vials of 15 ml, each 1 ml of clear aqueous sterile solution for injections contains 50 mg tocainide hydrochloride.

Uses Tonocard can be used for both treatment and prophylaxis of acute and chronic ventricular arrhythmias, including those complicating myocardial infarction.

Dosage and administration *Acute Treatment:* 500–750 mg by slow intravenous injection (or by infusion, diluted in 50–100 ml saline or glucose) given over 15–30 minutes, followed immediately by 600–800 mg orally.

Maintenance treatment: 8 hours after acute treatment, commence maintenance therapy with 1200 mg daily, divided into two or three oral doses.

Chronic ventricular arrhythmias: 1200 mg daily, divided into two or three oral doses.

The oral daily dosage of Tonocard may be increased to 1800–2400 mg in divided doses, if necessary.

Not to be administered to children.

Contra-indications, warnings, etc *Contra-indications:* Known hypersensitivity to amide drugs. Second or third degree A.V. block, in the absence of a pacemaker.

Precautions: Like other drugs, Tonocard should be used with caution in patients with severe hepatic or renal disease and in the elderly because of the potential risk of accumulation. Caution is also advised in patients with uncompensated heart failure and in patients receiving other antiarrhythmic agents.

Reproduction studies in animals have shown maternal and foetal toxicity. The safety of Tonocard in human pregnancy has not been tested and the potential benefit should be weighed against possible hazard.

Side-effects: Side effects during Tonocard treatment are generally mild and transient. Reported side effects are mainly neurological or gastro-intestinal. CNS symptoms are usually dose-related and may include tremor, dizziness, lightheadedness, convulsions and paraesthesia. Gastro-intestinal symptoms include nausea and vomiting. Rash and fever have been reported. Bradycardia and hypotension may occur after i.v. injection. Positive ANF titres, clinical manifestation of LE syndrome and fibrosing alveolitis have been reported during Tonocard therapy. Agranulocytosis or transient neutropenia has occurred in a few patients taking Tonocard, although a causal relationship has not been established.

Pharmaceutical precautions Recommended diluents for i.v. injection are sterile glucose solution or sterile saline.

Legal category POM.

Package quantities *Tablets:* 400 mg, bottle of 100 tablets; 600 mg, bottle of 100 tablets.

Injection: Packs of 5 × 15 ml injection vials.

Further information Tonocard is a primary amine analogue of lignocaine, with a high oral bio-availability. Its electro-physiological properties are similar to lignocaine and, as such, Tonocard has been shown to be effective in the treatment of ventricular arrhythmias. In therapeutic plasma concentration, no clinically significant adverse haemodynamic changes have been reported, even in patients with acute myocardial infarction or those pre-treated with beta-blockers.

600 mg tablets	0017/0107
50 mg/ml i.v. Solution	0017/0108

XYLOCAINE*

Presentation Clear aqueous sterile solution for injection. Each millilitre contains:

0.5% solution:	lignocaine hydrochloride anhydrous	5 mg
1% solution:	lignocaine hydrochloride anhydrous	10 mg
1.5% solution:	lignocaine hydrochloride anhydrous	15 mg
2% solution:	lignocaine hydrochloride anhydrous	20 mg

Uses Local anaesthetic solution without vasoconstrictor for infiltration anaesthesia, nerve blocks, intravenous regional blocks and analgesia.

Dosage and administration The dosage for local anaesthetics must be judged for each individual patient. Basically it should be remembered that the smallest dose producing the desired result should be given. Maximum dosage for adults of average body weight (70 kg) is 200 mg. Dosages for debilitated and aged patients should be appropriately reduced. For children, smaller amounts in lower concentrations should be administered, dependent on body weight.

The 1% solution in doses up to 20 ml and 2% solution in doses up to 10 ml should be reserved for nerve blocks.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage, route of administration and state of the patient. The reactions are primarily of two types typified by stimulation and depression of the cerebral cortex and medulla respectively. Adequate resuscitation equipment must be available whenever local or general anaesthesia is administered. Though clinical tolerance is remarkably good, overdosage or accidental intravenous injection may give rise to toxic reactions.

Special precautions: Care should be observed in patients suffering from epilepsy.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

XYLOCAINE* WITH ADRENALINE 1 : 200,000

Presentation Clear sterile aqueous solution for injection. Each millilitre contains:

0.5% solution:	lignocaine hydrochloride anhydrous	5 mg, Adrenaline BP 0.005 mg.
1% solution:	lignocaine hydrochloride anhydrous	10 mg, Adrenaline BP 0.005 mg.
2% solution:	lignocaine hydrochloride anhydrous	20 mg, Adrenaline BP 0.005 mg.

Uses Local anaesthetic solution with vasoconstrictor for infiltration anaesthesia, nerve blocks and analgesia.

Dosage and administration The dosage for local

anaesthetics must be judged for each individual patient. Basically it should be remembered that the smallest dose producing the desired result should be given. Maximum dosage for adults of average body weight (70 kg) is 500 mg. Dosage for debilitated and aged patients should be appropriately reduced. For children, smaller amounts in lower concentrations should be administered, dependent on body weight.

In operative fields the 0.5% solution may be used for infiltration anaesthesia. The 1% solution in doses up to 50 ml and the 2% solution in doses up to 25 ml should be reserved for nerve blocks.

Contra-indications, warnings, etc Hypersensitivity to local anaesthetics of the amide type. The use of vasoconstrictor is contra-indicated for analgesia of fingers, toes, tip of nose, ears and penis.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage, route of administration and state of the patient. The reactions are primarily of two types, typified by stimulation and depression of the cerebral cortex and medulla respectively. Adequate resuscitation equipment must be available whenever local or general anaesthesia is administered. Though clinical tolerance is remarkably good, overdosage or accidental intravenous injection may give rise to toxic reactions.

Precautions: Care should be observed in patients taking tricyclic antidepressants; patients suffering from epilepsy. Xylocaine solutions containing vasoconstrictors are suitable for routine use. Whenever possible solutions containing vasoconstrictors should be used to prolong anaesthesia and to reduce systemic absorption. This is especially important in highly vascularised areas.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

XYLOCAINE* 2%

Presentation Sterile aqueous solution for injection: lignocaine hydrochloride 20 mg/ml.

Uses Local anaesthetic solution without vasoconstrictor for dental anaesthesia where there is no need for profound ischaemia in the area injected. For all dental nerve-block techniques.

Dosage and administration Infiltration – 1 ml. Nerve block – 1.5–2 ml.

In adults the maximum total dose of Xylocaine is 200 mg.

In children the maximum dose is considerably less and should be calculated in relation to body weight.

Contra-indications, warnings, etc Known hypersensitivity to local anaesthetics of the amide type.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage, route of administration and state of the patient. The reactions are primarily of two types, typified by stimulation and depression of the cerebral cortex and medulla respectively. Slow onset – stimulation leading to nervousness, dizziness, blurred vision, nausea, tremor convulsions and respiratory arrest. Rapid onset – depression leading primarily to respiratory arrest, cardiovascular collapse and cardiac arrest.

Precautions: Adequate resuscitation equipment must be available whenever local or general anaesthesia is administered. Though clinical tolerance is extremely good, overdosage or accidental intravenous injection may give rise to toxic reactions.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities 2 ml glass cartridges in boxes of 100.

Further information Dental cartridges of Xylocaine 2% contain methylhydroxybenzoate 1 mg/ml.

Product licence number 0017/5026.

XYLOCAINE* 2% WITH ADRENALINE 1 : 80,000

Presentation Sterile clear aqueous solution: lignocaine hydrochloride 20 mg/ml, Adrenaline BP 1 : 80,000.

Uses Local anaesthetic solution with vasoconstrictor for dental infiltration anaesthesia where a vasoconstrictor is indicated. For all dental nerve-block techniques.

Dosage and administration Infiltration – 1 ml. Nerve block – 1.5–2 ml. Extensive surgery – 3–5 ml. Adult maximum dose 500 mg.

In children the maximum dose is considerably less and should be calculated in relation to the body weight.

Contra-indications, warnings, etc Patients with thyrotoxicosis and cardiac disease, particularly with arrhythmia or hypertension. Known hypersensitivity to local anaesthetics of the amide type.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage, route of administration and state of patient, the reactions are primarily of two types, typified by stimulation and depression of the cerebral cortex and medulla respectively. Slow onset – stimulation leading to nervousness, dizziness, blurred vision, nausea, tremor convulsions and respiratory arrest. Rapid onset – depression leading primarily to respiratory arrest, cardiovascular collapse and cardiac arrest. Symptoms occur rapidly and with little warning.

Precautions: Adequate resuscitation equipment must be available whenever local or general anaesthesia is administered. Though clinical tolerance is remarkably good, overdosage or accidental intravenous injection may give rise to toxic reactions. These are best avoided by aspiration before making an injection in order to avoid accidental intravascular injection.

Care should be observed in patients taking tricyclic anti-depressants.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Glass cartridges of 2 ml standard, and 2 ml self-aspirating, in boxes of 100.

Further information Dental cartridges of Xylocaine 2% with adrenaline 1 : 80,000 contain methylhydroxybenzoate 1 mg/ml.

Product licence number 0017/5027.

XYLOCAINE* ANTISEPTIC GEL

Presentation Clear sterile viscous gel. Each millilitre contains Lignocaine Hydrochloride BP 21.4 mg (equivalent to 20 mg lignocaine hydrochloride anhydrous), Chlorhexidine Gluconate Solution BPC 0.0025 ml in a water-miscible base.

Uses Anaesthetic gel for anaesthesia of the urethra and topical application on mucous membrane wherever an anaesthetic/antiseptic effect is required.

Dosage and administration *Men:* 10 ml injected initially, followed by 3–5 ml.

Women: 3–5 ml injected into the urethra.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 15 ml tubes.

Further information Nil.

Product licence number 0017/5035.

XYLOCAINE* 4% EYE DROPS

Presentation Sterile clear aqueous solution (isotonic). Each millilitre contains lignocaine hydrochloride anhydrous 40 mg.

Uses To anaesthetise the cornea and conjunctiva for removal of foreign bodies. Surgical procedures. Inflammation due to excessive glare (as in welders), and in conjunction with tonometric procedures.

Dosage and administration One or two drops as necessary.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Pharmaceutical precautions To be stored at room temperature.

Legal category POM.

Package quantities 4 ml dropper bottles.

Further information Nil.

Product licence number 0017/5036.

XYLOCAINE* GEL

Presentation Sterile clear gel. Each millilitre contains

Lignocaine Hydrochloride BP 21.4 mg (equivalent to 20 mg lignocaine hydrochloride anhydrous).

Uses Gel for anaesthesia of the urethra.

Dosage and administration *Men:* 10 ml injected initially, followed by 3–5 ml.

Women: 3–5 ml injected into the urethra.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 20 g tubes.

Further information Nil.

Product licence number 0017/5037.

XYLOCAINE* OINTMENT 5%

Presentation White cream. Each gramme contains lignocaine base 50 mg in a water-miscible vehicle.

Uses Local anaesthetic for topical use in dentistry for surface anaesthesia of the gums, and for the relief of soreness of the nipples in nursing mothers, pain relief in pruritus ani and vulvae, haemorrhoids, herpes zoster and labialis. As a lubricant for proctoscope and cystoscope.

Dosage and administration In dentistry, apply to dry gum and rub gently. For soreness of nipples, apply on a small piece of lint or gauze (to be washed off immediately before next feeding). For other indications, apply when required.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Pharmaceutical precautions Xylocaine ointment is not intended for use with aseptic techniques, nor is it bactericidal.

Legal category P.

Package quantities 15 g tubes.

Further information Nil.

Product licence number 0017/5038.

XYLOCAINE* SPRAY

Presentation Clear spray solution. Each gram contains 100 mg lignocaine base, 0.1 mg cetyl pyridinium chloride.

Uses Anaesthetic solution for surface analgesia of mucous membrane in ENT surgery, obstetrics and dental surgery.

Dosage and administration The spray is supplied in metered spray bottles. Each metered dose contains 10 mg of lignocaine base. The number of sprays needed depends upon the extent of the area to be anaesthetised. Maximum adult dosage based on body weight of 70 kg is 200 mg, equal to 20 spray doses. Maximum dosage in children is proportionately lower according to body weight.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Side-effects: Does not produce side-effects when used at the recommended dosage.

Adverse reactions: The type of toxic reaction is unpredictable and depends on dosage and state of the patient. The reactions are primarily of two types, typified by stimulation and depression of the cerebral cortex and medulla respectively.

Precautions: The spray should not come in contact with the eyes. Accidental application should be counteracted by immediate instillation of pure liquid paraffin followed by a boric acid (2–3%) wash.

Pharmaceutical precautions Store in a cool place. Keep away from excessive heat and direct sunlight. Empty container must not be thrown on to a fire or other source of heat.

Legal category P.

Package quantities Supplied in spray bottles of 80 g (approx. 800 spray doses) with a metering valve complete with adjustable spray nozzle which can be steam sterilised at 115°C or 121°C.

Further information Nil.

Product licence number 0017/5039.

XYLOCAINE* 4% TOPICAL

Presentation Clear aqueous solution. Each millilitre contains 40 mg lignocaine hydrochloride anhydrous.

Uses Anaesthesia of mucous membrane in bronchoscopy and bronchography; biopsy in the mouth and throat; puncture of the maxillary sinus or polypectomy; tonsillectomy; resection of nasal turbinates; in dentistry.

Dosage and administration *Bronchoscopy and bronchography:* With a suitable spray 2–3 ml Xylocaine 4% may be applied to the mouth, pharynx, larynx and trachea.

Biopsy: 3–4 ml may be sprayed on the area or the solution may be applied for a few minutes with a swab. Adrenaline may be added to this solution in order to produce vasoconstriction (add 1–2 drops, 0.05 ml, 1 : 1,000, solution to 5 ml Xylocaine 4% solution).

Puncture of maxillary sinus or polypectomy: A swab soaked in the solution may be applied for two to three minutes. The addition of adrenaline is advised in these procedures, made up on the lines indicated above.

The maximum adult dose (70 kg body weight) should not exceed 5 ml (200 mg). For the debilitated, the aged and children the dosage should be reduced. In children the maximum dose is calculated as 1.4 mg per lb, or 3 mg/kg.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Precautions: Adrenaline added to the solution as described above decomposes fairly rapidly. A freshly prepared solution should be made up and used within a few hours or discarded.

Pharmaceutical precautions Store at room temperature.

Legal category P.

Package quantities Bottles of 25 ml.

Further information Nil.

Product licence number 0017/5040.

XYLOCAINE* VISCOUS

Presentation Viscous clear liquid. Each millilitre contains Lignocaine Hydrochloride BP 21.4 mg (equivalent to 20 mg lignocaine hydrochloride anhydrous).

Uses Topical anaesthetic solution for:

1. Mucous membrane lesions of mouth and throat following tonsillectomy, and post-tonsillectomy sore throat.
2. Introduction of instruments and catheters into the stomach.
3. Oesophagoscopy, oesophagitis, pharyngitis and stomatitis.
4. Severe hiccough.

Dosage and administration

1. One teaspoonful (5 ml) swished around the mouth and swallowed slowly. (Not more than six times in 24 hours.)
2. One tablespoonful (15 ml).
3. One dessertspoonful (10 ml) swished around the mouth and swallowed slowly. (Not more than three times in 24 hours.)
4. One dessertspoonful (10 ml) swallowed quickly in one gulp. (Not more than three times in 24 hours.)

The maximum dose for adults of normal body weight is 15 ml. This should be reduced for debilitated and aged patients.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type. There are no known side-effects or adverse reactions.

Precautions: No food or drink should be taken for three hours after administration. Not more than 30 ml to be administered in 24 hours. Minimal interval between doses – four hours.

Pharmaceutical precautions None.

Legal category P.

Package quantities Bottles of 150 ml.

Further information Nil.

Product licence number 0017/5041.

XYLOCARD*

Presentation *Xylocard 100 mg Intravenous bolus injection:* Clear aqueous sterile solution in pre-loaded syringe 5 ml: lignocaine hydrochloride anhydrous 20 mg/ml.

Xylocard 1 g and 2 g: Sterile aqueous solution in pre-loaded 5 ml or 10 ml syringe: lignocaine hydrochloride anhydrous 200 mg/ml.

Uses Prevention of ventricular tachyarrhythmias in patients with suspected or proven acute myocardial infarction. Treatment of ventricular tachyarrhythmias associated with acute myocardial infarction. Ventricular extrasystoles and ventricular tachycardia. As anti-arrhythmic cover in cases of ventricular fibrillation being DC converted.

Dosage and administration *Adults:* *Xylocard 100 mg Intravenous:* 1 mg/kg body weight Normal dose

(adults) 50–100 mg (2.5–5 ml) as initial treatment to be injected slowly over a period of two minutes. When necessary injection can be repeated once or twice at 5–10 minute intervals. Effect can be observed within two minutes.

Xylocard 1 g and 2 g for addition to I.V. Infusion: A concentration of 0.2% lignocaine infusion may be recommended for most cases. This is achieved by adding 1 × Xylocard 1 g syringe (or $\frac{1}{2}$ × Xylocaine 2 g syringe) to 500 ml infusion solution. Normal dose (adults) 2–4 mg/min. Based on a concentration of 0.2% this is equivalent to an infusion rate of 1–2 ml/min.

Not to be administered to children.

Contra-indications, warnings, etc Lignocaine is contra-indicated in patients with a known history of hypersensitivity.

Arterioventricular block is an absolute or relative contra-indication, according to severity.

Other serious conduction disturbances, and cardiac decompensation not dependent on treatable tachyarrhythmias, are also contra-indications.

Side-effects: *CNS (cortex):* Agitation, drowsiness, disorientation, blurred vision, euphoria, tremor and convulsions.

CNS (medullary): Nausea, pallor, cold sweat, respiratory depression.

Cardiovascular: Fall in blood pressure, bradycardia, cardiac arrest.

Patients with severe liver damage should be given lower doses and the effect carefully monitored. Manifest renal insufficiency calls for special care in infusion therapy.

Pharmaceutical precautions Store in a cool place.

The content of the Xylocard 1 g and 2 g syringe is for dilution in infusion fluid only. Under no circumstances are they to be administered undiluted.

Legal category POM.

Package quantities *Xylocard 100 mg 5 ml (20 mg/ml):* Pre-loaded syringe for immediate use. Box of 5.

Xylocard 1 g (5 ml) and Xylocard 2 g (10 ml) both 200 mg/ml: Pre-loaded syringe for addition to infusion bottles and bags. Box of 10.

Further information All Xylocard syringes are free of bacteriostat and preservatives.

Product licence numbers

Xylocard 100 mg I.V. bolus	0017/5018
Xylocard 1 g I.V. infusion	0017/0064
Xylocard 2 g I.V. infusion	0017/0064

XYLODASE*

Presentation White cream. Each gram contains lignocaine (base) 50 mg, Hyaluronidase BP 50 units (0.015%) in water-miscible base.

Uses Surface anaesthesia in dental procedures: surface analgesia before any injection, opening of abscesses, preparation of sensitive cervical cavities, deep scaling, extraction of deciduous teeth not embedded deeply in the bone, wiring of teeth.

Dosage and administration $\frac{1}{2}$ –1 g or as required.

Contra-indications, warnings, etc Known hypersensitivity to anaesthetics of the amide type.

Pharmaceutical precautions To be stored at room temperature.

Legal category P.

Package quantities Boxes of 12 × 15 g tubes.

Further information Nil.

Product licence number 0017/5042.

XYLOPROCT* OINTMENT

Presentation White water-miscible cream. Each gram contains: Xylocaine (lignocaine) 50 mg, Hydrocortisone Acetate BP 2.75 mg, Zinc Oxide BP 180 mg, aluminium acetate 35 mg.

Uses External and prolapsed haemorrhoids and other painful perianal conditions.

Pruritus ani – pruritus vulva.

Dosage and administration To be applied several times a day according to the severity of the condition.

Contra-indications, warnings, etc There are no known contra-indications or side-effects.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities *Tubes:* 30 g ointment complete with special applicator.

Further information Nil.

Product licence number 0017/5023.

XYLOPROCT* SUPPOSITORIES

Presentation White cone-shaped suppositories. Each suppository contains: Xylocaine (lignocaine) 60 mg, hydrocortisone Acetate BP 5 mg, Zinc Oxide BP 400 mg, Aluminium acetate 50 mg.

Uses For the treatment of internal haemorrhoids and other disorders of the anal canal such as proctitis, fissure in ano, anal fissure and anal fistula.

Dosage and administration Removing protective foil, use 1 suppository at night before retiring and repeat the treatment after each bowel action.

Contra-indications, warnings, etc There are no known contra-indications or side-effects.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Packs containing 10 separate foil-protected suppositories.

Further information Nil.

Product licence number 0017/5024.

ZELMID* ▼

Presentation Zelmid (zimelidine dihydrochloride, INN) is available as white film coated tablets: Zelmid 100 mg, round, marked $\frac{Z}{100}$, Zelmid 200 mg, oval marked $\frac{Z}{200}$.

Uses The molecular structure of Zelmid is different to that of tricyclic antidepressants. As a result of this, it has different pharmacological properties.

Zelmid inhibits the re-uptake of 5-hydroxytryptamine (5-HT) into CNS pre-synaptic nerve terminals. It has only a minor effect on the re-uptake of noradrenaline and is without a direct effect on dopamine. Zelmid, therefore, preferentially enhances transmission in 5-HT neuronal systems. The anticholinergic action of Zelmid is extremely weak and it has no antihistaminic activity.

Indications: In the management of major depressive illness.

Dosage and administration *Route of Administration:* Oral.

Dosage: *Adults: Non-Elderly:* 200 mg as a single dose during the day. This can be taken in two divided doses if needed. In non-responders at 200 mg the dosage may be increased to 300 mg in divided daily doses.

Elderly: As a reduction in eliminatory capacity may be present in this age group, a single daily dose of 100 mg is recommended. Non-responders at this dose level may receive 200 mg daily in 2 divided doses.

Children: Not recommended, as currently no clinical data is available.

Contra-indications, warnings, etc *Contra-indications:* Mania, severe liver disease, patients who are hypersensitive to Zelmid. Do not use in pregnancy nor in nursing mothers.

Precautions: Until further clinical experience is obtained, care must be exercised in patients suffering from uncontrolled epilepsy and lowered seizure threshold.

Although Zelmid has only weak anticholinergic properties it should be used cautiously in patients with conditions which would worsen under anticholinergic influence (e.g. narrow angled glaucoma, urinary retention, increased intra-ocular pressure, etc.) until further clinical experience is gained.

As with all drugs, patients suffering from hepatic, renal or cardiac insufficiency, recent myocardial infarction, heart block or arrhythmias should be carefully monitored during Zelmid therapy. Animal work has shown adverse effects on sexual performance and this effect might occur in patients.

As a general principle, elderly and debilitated patients should be carefully monitored during therapy with antidepressants, including Zelmid.

Patients with severe depression who pose a high suicide risk should be kept under close surveillance, particularly during the early stages of treatment.

Interactions: The use of monoamine oxidase inhibitors should be discontinued 2 weeks before the start of Zelmid therapy.

Although interaction between Zelmid and antihypertensive drugs has not been recorded a review of

antihypertensive therapy during Zelmid treatment is advisable.

Although interaction with sympathomimetic agents has not been reported with Zelmid, care should be taken when given concomitantly with adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine, and phenylpropanolamine.

The possibility that Zelmid might potentiate the CNS depressant effect of alcohol has not been excluded.

Warnings and adverse reactions: Anticholinergic side-effects have been reported less frequently with Zelmid than with standard antidepressants.

As with all drugs, if surgery is necessary Zelmid therapy must be reported to the anaesthetist.

Although Zelmid does not induce sedation which can lead to impairment of psychomotor skills, depressed patients should be warned to exercise extra care when driving or operating hazardous machinery.

Zelmid is generally well tolerated. Side effects reported to date have been mild and transient in nature. The most common side effects observed are headache, nausea, indigestion and perspiration. Single cases of postural hypotension and clinically non-significant ECG changes have been reported. Isolated cases of allergic reaction, reversible anaemia, leucopaenia, thrombocytopenia and transient increases in transaminases have been reported.

Overdosage: There is no specific antidote to Zelmid. Patients should be monitored carefully and given supportive treatment when necessary.

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities 100 mg: bottles of 100.
200 mg: blister packs of 28.

Further information Zelmid does not increase appetite, and unlike tricyclic antidepressants, inappropriate weight gain does not occur. Zelmid does not enhance the CNS depressant effect of benzodiazepines. This could be of advantage if concomitant use is necessary.

At levels of Zelmid which effectively prevent 5-HT re-uptake, the effect on other pharmacological systems is negligible or not measurable. The risk of a direct pharmacological interaction between Zelmid and other groups of drugs (e.g., antihypertensives, anticholinergics, alcohol, etc.) is, therefore, less than for those antidepressants which have a wide spectrum of pharmacological activity.

ANTEPSIN[®] TABLETS ▼

Presentation Antepsin Tablets 1 gram are white, oblong, biconvex, uncoated tablets scored on one side branded 1239 and Ayerst and containing 1 gram sucralfate.

Uses For the treatment of duodenal ulcer, gastric ulcer and chronic gastritis.

Dosage and administration For oral administration: *Adults*: Usual dose 1 gram 4 times a day. Maximum daily dose 8 grams. Tablets to be taken 1 hour before meals and at bedtime.

Four to six weeks' treatment is usually needed for ulcer healing but up to twelve weeks may be needed in resistant cases.

Antacids may be used as required for relief of pain.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications.

Precautions: 1. Concomitant administration with some oral anti-infectives such as tetracyclines may interfere with absorption of the latter.

2. The product should only be used with caution in patients with renal dysfunction.

3. As with all medicines Antepsin should not be used in early pregnancy unless considered essential.

Side-effects: A low incidence of mild side-effects, e.g. constipation has been reported.

Pharmaceutical precautions No special requirements for storage are necessary.

Legal category POM.

Package quantities Antepsin 1 gram: Securitainers of 100.

Further information Antepsin is not significantly absorbed. It forms a chemical complex which selectively binds to the ulcer site, establishing a protective barrier against the actions of pepsin bile and gastric acid.

Product licence number 0607/0045.

BC 500[®]

Presentation BC 500 is a high-potency B complex and C vitamin tablet. Each tablet contains:

Thiamine mononitrate (vit. B ₁)	25 mg
Riboflavin (vit. B ₂)	12.5 mg
Nicotinamide	100 mg
Pyridoxine hydrochloride (vit. B ₆)	10 mg
Calcium pantothenate	20 mg
Cyanocobalamin (vit. B ₁₂)	5 mcg
Ascorbic acid (vit. C) as sodium ascorbate	500 mg

BC 500 is an orange, oblong, film-coated tablet printed 'Ayerst 824'.

Uses BC 500 is indicated whenever the administration of high-potency B complex and C vitamins is needed. Such conditions include: Convalescence. Chronic alcoholism. Old age and associated poor diet. Prolonged antibiotic therapy. Debilitating disease, including ulcerative colitis, colostomy, gastric and duodenal ulcer.

Dosage and administration Recommended only for adults. One tablet daily.

Contra-indications, warnings, etc As is usual with water-soluble vitamins there are no known contra-indications.

Precautions: Pyridoxine may antagonise laevodopa when given for Parkinson's Disease.

Overdosage: BC 500 contains only water soluble vitamins and overdosage is unlikely to be a problem.

Pharmaceutical precautions No special requirements for storage are necessary.

Legal category P.

Package quantities Securitainers of 100 and 500 tablets.

Further information BC 500 contains high doses of the B complex and 500 mg vitamin C. This means that a once a day dosage provides adequate vitamins even when requirements are high.

Product licence number 0607/0011.

BC 500[®] WITH IRON

Presentation BC 500 with Iron tablets contain high potency B complex and C vitamins with ferrous fumarate. Each tablet contains:

Ferrous Fumarate	200 mg
Thiamine Mononitrate	25 mg
Riboflavin	12.5 mg
Nicotinamide	100 mg
Pyridoxine Hydrochloride	10 mg
Calcium Pantothenate	20 mg
Ascorbic Acid as Sodium Ascorbate	500 mg

BC 500 with Iron is a red film-coated round biconvex tablet printed Ayerst 1143.

Uses BC 500 with Iron tablets are recommended for the treatment of iron deficiency when therapeutic doses of water soluble vitamins are also required.

Dosage and administration One tablet daily or as recommended by the physician. Recommended only for adults. Keep out of reach of children.

Contra-indications, warnings, etc **Precautions:** Iron chelates with tetracyclines and may impair absorption of both agents. Pyridoxine may antagonise laevodopa when given for Parkinson's Disease.

Side-effects: As with all iron preparations, nausea,

gastro-intestinal irritation and constipation may rarely occur.

Overdose: In the event of overdose emesis and/or gastric lavage is indicated. Immediate injection of 2 g desferrioxamine mesylate in water for injection is required. After gastric lavage 5 g of desferrioxamine mesylate in 50–100 ml of water may be left in the stomach.

Pharmaceutical precautions No special requirements for storage are necessary.

Legal category P.

Package quantities Securitainers of 100 and 500 tablets.

Further information The dose of Vitamin C is sufficient both to treat deficiency of this vitamin and to enhance the absorption of iron.

Product licence number 0607/0028.

CALTHOR* TABLETS ▼ CALTHOR* SUSPENSION ▼

Presentation Calthor Tablets are white, round, flat and scored one side, containing 250 mg or 500 mg ciclacillin. The 250 mg tablets are 10 mm in diameter and 4.4 mm thick. The 500 mg tablets are 13 mm in diameter and 5 mm thick.

Calthor Suspension 125 mg is presented as a granular off-white powder. When reconstituted it is a pale orange, homogenous suspension with a characteristic fruity smell, containing 125 mg ciclacillin per 5 ml. Calthor Suspension 250 mg is presented as a granular off-white powder. When reconstituted it is an off-white, homogenous suspension with a characteristic fruity smell containing 250 mg ciclacillin per 5 ml.

Uses Calthor is an orally active broad spectrum penicillin. Calthor is indicated for the oral treatment of a wide range of bacterial infections caused by commonly occurring pathogens.

Calthor is active against the following organisms *in vitro*: Group A beta-haemolytic streptococci, *Strep. faecalis* (enterococci), alpha-haemolytic streptococci, *Strep. pneumoniae*, non-penicillinase-producing staphylococci, *Haemophilus influenzae*, *Escherichia coli*, *Proteus mirabilis*, *Neisseria gonorrhoeae*. All strains of pseudomonas and most strains of klebsiella and enterobacter are resistant: some strains of *E. coli* and *H. influenzae* may be resistant. Calthor should not be used in any infections caused by *E. coli* and *P. mirabilis* other than urinary tract infections. Efficacy against salmonella infections has not been established.

Calthor is indicated for the treatment of the following infections, due to susceptible organisms:

Respiratory Tract infections, *e.g.*: Tonsillitis, pharyngitis, bronchitis, pneumonia,
Otitis Media,
Skin and Skin Structure (Integumentary) infections,
Urinary Tract infections.

Dosage and administration *Preparation of the suspension:* 125 mg/5 ml – add 57 ml of water to the powder for reconstitution and shake well.

250 mg/5 ml – add 74 ml of water to the powder for reconstitution and shake well.

Adults: Respiratory Tract Infections: Tonsillitis and Pharyngitis 250 mg qid in equally spaced doses.

Bronchitis and Pneumonia:

Mild or moderate infections – 250 mg qid in equally spaced doses.

Chronic infections – 500 mg qid in equally spaced doses.

Otitis Media: 250 mg to 500 mg qid in equally spaced doses depending on severity.

Skin and Skin Structure Infections: 250 mg to 500 mg qid in equally spaced doses depending on severity.

Urinary Tract Infections: 500 mg qid in equally spaced doses.

Children: 2 months to 10 years – half adult dose. Over 10 years – adult dose.

All recommended dosages are a guide only. In severe infections dosages may be increased.

In infections caused by Group A beta-haemolytic streptococci a minimum of 10 days of treatment is recommended to guard against the risk of rheumatic fever or glomerulonephritis.

In the treatment of chronic urinary tract infection frequent bacteriological and clinical appraisal is necessary during therapy and may be required for several months afterwards. Persistent infection may require treatment for several weeks.

Calthor should not be used in children under 2 months of age.

Patients with renal failure: Each patient should be individually considered. Based on a dosage of 500 mg qid the following adjustment in dosage interval is recommended:

Patients with a creatinine clearance of 50 ml/min need no dosage interval adjustment.

Patients with a creatinine clearance of 30–50 ml/min should receive a full dose every 12 hours.

Patients with a creatinine clearance of between 15–30 ml/min should receive full doses every 18 hours.

Patients with a creatinine clearance of between 10–15 ml/min should receive full doses every 24 hours.

In patients with a creatinine clearance of ≤ 10 ml/min or serum creatinine values of ≥ 10 mg per 100 ml, serum ciclacillin levels are recommended to determine the subsequent dosage and frequency.

Contra-indications, warnings, etc

Contra-indications: Calthor should not be given to patients with a history of hypersensitivity to penicillin.

Precautions: Animal experiments show no teratogenic effect but, as with all medicines, Calthor should not be administered during pregnancy unless considered essential. Because many drugs are excreted in human milk, caution should be exercised when Calthor is administered to a nursing mother.

Prolonged use of an anti-infective may result in overgrowth of non-sensitive organisms.

Side-effects: Calthor is generally very well tolerated and side-effects are rare. Diarrhoea, nausea, vomiting and skin reactions have occasionally been observed.

Penicillins may cause an acute anaphylactic reaction which can be fatal. This reaction appears to occur more frequently in patients with bronchial asthma or other allergic disorders.

Overdosage: Since Calthor is a penicillin problems of overdosage are unlikely to be encountered.

Pharmaceutical precautions Store in a cool place.

After reconstitution the suspension should be stored in a refrigerator and the unused portion discarded after 14 days. When stored at room temperature discard

unused portion after 8 days. The suspension may be diluted with syrup BP.

Legal category POM.

Package quantities

Tablets: Cartons of 120 tablets in blister packs of twelve.

Suspension: Bottles containing powder to give 120 ml reconstituted suspension.

Further information Ciclacillin is very rapidly and well absorbed from the gastro-intestinal tract after oral administration to give exceptionally high peak levels within 30–40 minutes. A high proportion is excreted unchanged in the urine within 6 hours.

EVADYNE* TABLETS

Presentation Evadyne Tablets 25 mg are orange, film-coated, round, bi-convex tablets containing butriptyline 25 mg as the hydrochloride.

Evadyne Tablets 50 mg are pink, film-coated, round, bi-convex tablets containing butriptyline 50 mg as the hydrochloride.

Uses Evadyne is indicated for the relief of depression with or without associated anxiety.

Evadyne is particularly useful in ambulatory patients because it is generally well tolerated and shows, after an early relief of anxiety, a gradual mood elevation with a disappearance of symptoms of self-deprecation, disinterest, fatigue, apathy and anorexia when present.

Evadyne has proved useful in cases resistant to other presently available antidepressant therapy. The drug may relieve depressive reactions and associated anxiety accompanying chronic illness.

Dosage and administration *Adults: Initial dosage:* Usually 25 mg three times daily (75 mg total daily dose).

Adjustment: The initial dose may be increased in steps of 25 mg every day or every other day to attain a level of 100–150 mg maximum total daily dose.

Maintenance dosage: When a satisfactory response is achieved the dose may be gradually reduced to 25 mg three times a day.

Formulations for children are not yet available.

Contra-indications, warnings, etc

Contra-indications: Combined use with other psychotropic drugs should be undertaken only with due recognition of the possibility of potentiation. Patients having received monoamine oxidase inhibitors (MAOI) should not be given Evadyne until at least two weeks after cessation of MAOI therapy. Evadyne is not recommended for use in pregnant patients as clinical experience and follow-up have as yet been limited. However, animal reproductive studies have shown no foetal malformations.

Precautions: As in the case of all psychotropic compounds, Evadyne may impair alertness in some patients; thus, activities made hazardous by diminished alertness should be avoided (e.g. driving). It should be used with caution in patients with a history of epileptiform seizures.

Patients should be cautioned against the ingestion of alcohol during therapy due to the danger of potentiation.

Evadyne may interact with adrenergic drugs and care must be taken if such a combination is to be used.

As with other dibenzocycloheptene derivatives, Evadyne should not be used in patients with glaucoma or those who would be expected to experience urinary retention.

Patients with known cardiovascular disorders should be watched closely; frequent ECG monitoring is recommended.

Side-effects: Side-effects experienced with Butriptyline are usually mild and transitory in nature. Evidence of anticholinergic activity such as dry mouth and blurred vision, accommodation disturbances, constipation, paralytic ileus and urinary retention may be seen; however, these are usually dose related. In the majority of patients, these adverse reactions do not interfere with therapy and tend to diminish with continued treatment.

Because of pharmacological similarities between tricyclic antidepressant drugs, cardiovascular, CNS and neuromuscular adverse reactions, which have not particularly been reported with Evadyne, should also be considered.

Overdosage: There is no specific antidote for overdosage with tricyclic compounds. Induced emesis and gastric lavage are recommended.

If the patient is stuporous but responds to stimuli, only close watching may be required for a few days; if comatose, supportive measures will be required. Maintain an open airway and adequate fluid intake; regulate body temperature. Anticonvulsants may be given to control convulsions. Central nervous system depression may be treated with nonconvulsant doses of CNS stimulants.

Digitalis should be considered if cardiovascular abnormalities occur. Standard measures such as oxygen and i.v. fluids may be used to manage circulatory shock.

Pharmaceutical precautions No special pharmaceutical precautions are necessary.

Legal category POM.

Package quantities Evadyne Tablets 25 mg are packed in Securitainers of 100.

Evadyne Tablets 50 mg are packed in Securitainers of 100.

Further information Nil.

Evadyne Tablets 50 mg	0607/0020

HRF AYERST*

Presentation HRF Ayerst contains leutinising hormone/follicle stimulating hormone releasing hormone (LH/FSH-RH; gonadorelin) in a freeze-dried form. HRF Ayerst is available in 2 strengths, 100 mcg and 500 mcg, and is supplied with an ampoule of sterile diluent for injection.

Uses HRF Ayerst stimulates the release of gonadotrophins from a functional pituitary and is of diagnostic value in cases where determinations of pituitary reserve are required, e.g.

Female: Primary or secondary amenorrhoea, hypogonadotropic hypogonadism, Sheehan's Syndrome.

Male: Hypogonadotrophic hypogonadism, cryptorchism, Klinefelter's Syndrome, Frohlich's Syndrome.

Male and Female: Pituitary ablation, acromegaly, Cushing's Syndrome, Simmond's Syndrome, Kallman's Syndrome, etc.

In the differential diagnosis of delayed puberty and hypogonadotrophic hypogonadism, etc.

Dosage and administration *Routine determination of pituitary function:* For a rapid and simple determination of pituitary response capability, a single intravenous dose of 100 mcg is suggested.

Refined determination of pituitary function: To determine the threshold of pituitary response an initial dose of 25 mcg is recommended. This may be increased in steps until the pituitary threshold is determined. Doses as high as 500 mcg have been used for this purpose.

Blood samples: Venous blood samples should be taken before and at intervals after administration of HRF Ayerst. Arrangements should be made with a radio-immunoassay centre for measurement of LH and FSH in the samples.

Interpretation of results. The normal adult: In the normal adult an injection of 25–100 mcg of HRF Ayerst causes an increase in LH/FSH in a dose related manner. Peak circulating levels of LH are obtained within 10–30 minutes. An increase in serum FSH follows the same course but not to the same degree. Levels gradually fall during the next few hours, LH being elevated above base-line for four to six hours, and FSH for three to five hours. Frequent sampling shows that the secretion of gonadotrophins is pulsatile and synchronous. In the female the influence of gonadal steroids on pituitary responsiveness is less clear, as there is a cyclical variation in responsiveness depending upon the phase of the menstrual cycle, the maximum response being during the luteal phase. In the male feedback effects may be seen when gonadal steroids are administered in physiological and higher doses.

Absent response is defined as one in which the 100 mcg HRF Ayerst administration fails to produce a rise greater than three times the basal level of the gonadotrophins. An impaired response is said to occur if the elevation in circulating gonadotrophins is found but not within the normal range at 20–60 minutes. If the 60 minute value is the same or exceeds that at 20 minutes, the response is defined as delayed. Values outside the normal range at 20 or 60 minutes are considered to be exaggerated. Absent, impaired or exaggerated responses imply endocrine dysfunction. Delayed responses are not in themselves suggestive of pathology.

Reference to current literature will assist interpretation of results in pathological states.

Prepubertal children: In boys tested with HRF Ayerst there is an increasing LH response as puberty progresses from stage one to stage three. FSH secretion is less than for LH in all three stages of puberty and there are no significant differences between the results obtained at different stages.

In girls, FSH levels increase more markedly at stage one and then change little during puberty. LH response is slight at stage one and after stage two the levels achieved exceed that of FSH response resembling the normal adult pattern.

Contra-indications, warnings, etc Existing clinical experience has not shown any contra-indications to HRF Ayerst, but it should not be administered in

pregnancy. Administration during the follicular phase of a normal menstrual cycle may result in premature ovulation, and appropriate measures are advised to prevent an unwanted pregnancy in these circumstances.

Overdosage: with HRF Ayerst has never been reported and is unlikely to be a problem.

Pharmaceutical precautions HRF Ayerst has a shelf-life of four years. Store at room temperature. Use within 24 hours of reconstitution.

Legal category POM.

Package quantities Packs comprise a vial containing 100 mcg or 500 mcg freeze-dried material and a 2 ml ampoule of sterile diluent.

Further information HRF Ayerst is a synthetic decapeptide identical to the LH/FSH-RH identified by Schally and co-workers.

Combined test of pituitary function: Gonadorelin may be used in conjunction with TRH for a more complete evaluation of the hypothalamic-anterior pituitary-gonadal axis. TRH injection (2 ml) may be used in place of the diluent supplied with HRF Ayerst to prepare a combined injection. The HRF Ayerst/TRH mixture has been shown to be stable for 24 hours.

HRF Ayerst 500 mcg 0607/0017

ISORDIL*

Presentation Isordil Sublingual Tablets, containing isosorbide dinitrate 5 mg, are small, pink tablets specially formulated for sublingual administration.

Isordil Tablets, containing isosorbide dinitrate 10 mg, are white, convex, scored tablets for normal oral administration.

Isordil Tablets containing isosorbide dinitrate 30 mg are pale yellow biconvex tablets, scored one side.

Uses *Angina pectoris:* Sublingually for the acute attack. Orally for protection against anginal attacks.

Acute congestive heart failure including after myocardial infarction and *chronic congestive heart failure* as adjunctive therapy.

Dosage and administration *Acute attack of angina:* 1 tablet Isordil 5 mg sublingually as required with a maximum of 1 or 2 tablets every two hours.

Protection against anginal attacks: 40–120 mg daily in divided doses. In selected cases daily doses of up to 240 mg Isordil have been administered.

Chronic congestive heart failure: As adjunctive therapy.

Initial dosage: Sublingual Isordil 5 mg in doses of 5–10 mg every two hours or as needed.

Maintenance: The oral form of Isordil in doses of 10 mg to 60 mg four times daily.

Acute congestive heart failure including after myocardial infarction: Sublingual Isordil 5–15 mg every two to three hours or as needed. The oral form of Isordil may be administered in doses of 10–60 mg four times daily or as needed.

The therapeutic use of Isordil in selected cases of acute and chronic congestive heart failure should be considered as an adjunct to the more conventional modes of therapy such as the cardiac glycosides and

diuretics etc. Continuous haemodynamic monitoring of the patient under treatment is desirable and optimal dose regimens should be determined for individual cases depending on these results.

Contra-indications, warnings, etc

Contra-indications: Idiosyncrasy to this drug.

Precautions:

1. Tolerance to this drug and cross tolerance to other nitrates and nitrites, may occur.
2. In congestive heart failure, as a rule, pulmonary capillary pressure should not be allowed to fall below 15 mmHg or systolic blood pressure below physiological range in normal or hypertensive patients. In patients with hypotension in the range of 90–100 mmHg of systolic pressure there should be no fall at all. As with other vasodilators in sensitive patients Isordil may cause paradoxical side-effects which may increase ischaemia and may even lead to extension of myocardial damage and advanced congestive heart failure.

Adverse reactions: The adverse reactions due to Isordil are common to all nitrates used for the treatment of angina pectoris.

1. Cutaneous vasodilation with flushing.
2. Headache is common and in some patients may be severe and persistent. Analgesics have been useful in some cases.
3. Transient episodes of dizziness and weakness and other signs of cerebral ischaemia associated with postural hypotension may occur.
4. This drug can act as a physiological antagonist to noradrenaline, acetylcholine, histamine and many other agents.

Treatment of overdosage: Isordil is very safe (the LD₅₀ of isosorbide dinitrate in rodents is of the order of 1,000 mg per kg), so dangerous overdosage is extremely rare. In such cases, however, gastric lavage is indicated. Passive exercise of the extremities of the recumbent patient will promote venous return.

Pharmaceutical precautions *Storage:* Unlike glyceryl trinitrate, Isordil Tablets are stable and no special storage conditions are necessary.

Legal category P.

Package quantities Isordil Sublingual Tablets 5 mg in Securitainers of 100.

Isordil Tablets 10 mg in Securitainers of 100.
Isordil Tablets 30 mg in Securitainers of 100.

Further information Isordil has a very high solubility compared with other nitrates and therefore acts sublingually to abort the acute attack of angina pectoris quickly. In addition Isordil can be administered orally to give a prolonged effect. Because Isordil is physically and chemically stable it is reliable in use.

Isordil Tablets 10 mg 0607/0007
Isordil Tablets 30 mg 0607/0027

ISORDIL* TEMBIDS* CAPSULES

Presentation Isordil tembids capsules containing isosorbide dinitrate 40 mg in a sustained release formulation are gelatin capsules with a colourless, transparent body and opaque blue cap for oral administration.

Uses Prophylaxis of angina pectoris.

Dosage and administration For oral administration – One capsule 2 or 3 times a day.

Contra-indications, warnings, etc

Contra-indications: Idiosyncrasy to this drug.

Precautions: Tolerance to this drug, and cross-tolerance to other nitrates and nitrites may occur.

Adverse Reactions: The adverse reactions due to Isordil are common to all nitrates used for the treatment of angina pectoris.

1. Cutaneous vasodilation with flushing.
2. Headache is common and in some patients may be severe and persistent. Analgesics have been useful in some cases.
3. Transient episodes of dizziness and weakness and other signs of cerebral ischaemia associated with postural hypotension may occur.
4. This drug can act as a physiological antagonist to noradrenaline, acetylcholine, histamine and many other agents.

Treatment of overdosage: Isordil is very safe (the LD₅₀ of isosorbide dinitrate in rodents is of the order of 1,000 mg/kg), so dangerous overdosage is extremely rare. In such cases, however, gastric lavage is indicated. Passive exercise of the extremities of the recumbent patient will promote venous return.

Pharmaceutical precautions *Storage:* Unlike glyceryl trinitrate, Isordil Tembids are stable and no special storage conditions are necessary.

Legal category P.

Package quantities Securitainers of 100.

Further information Isosorbide dinitrate is released from the slow release formulation over a 6 hour period to provide up to 12 hours of sustained effect.

Product licence number 0607/0041.

MICROLET* MICRO-ENEMA

Presentation A disposable polyethylene tube with a 2" pliable nozzle which contains 5 ml of a clear, virtually colourless, viscous liquid, comprising 45 mg sodium lauryl sulphoacetate, 450 mg sodium citrate and 625 mg glycerol, together with potassium sorbate, citric acid, sorbitol and water.

Uses Microlet combines the action of sodium citrate, a 'peptizing' agent which liberates water present in the faeces; sorbitol which enhances this action; sodium lauryl sulphoacetate, a wetting agent, and glycerol which promotes peristalsis and evacuation of the lower bowel.

Microlet is indicated whenever an enema is necessary for chronic and acute constipation in the rectum and sigmoid colon. Constipation during pregnancy, encopresis, coprostasis, pre- and post-operative constipation, and as a preliminary to rectoscopic and sigmoidoscopic examinations.

Dosage and administration

Adults and Children Aged 3 years and Over: Lubricate the nozzle with one drop of the contents, insert full length of nozzle into the rectum and squeeze tube until total contents have been administered. Two tubes may be necessary in severe cases.

Children Under 3 years: Insert half the length of the nozzle into the rectum following the instructions as above.

Contra-indications, warnings, etc Very occasionally, a slight cramp may occur. Prolonged use may interfere with the absorption of some vitamins. Excessive use of Microlet Micro-enema may cause diarrhoea and fluid loss. In such cases Microlet should be discontinued and appropriate therapy instituted.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Packs of 12.

Further information Nil.

Product licence number 0607/0042.

PHOSPHOLINE IODIDE*

Presentation Each pack contains:

1. Ecothiopate iodide BP in a sterile, freeze-dried form mixed with 40 mg potassium acetate in a vial sufficient for: 5 ml of 0.03%, or 5 ml of 0.06%, or 5 ml of 0.125%, or 5 ml of 0.25%.

2. 5 ml sterile aqueous diluent containing chlorbutanol 0.5%, mannitol 1.2%, boric acid 0.06%, exsiccated sodium phosphate 0.026%.

3. A sterile dropper.

The 0.06%, 0.125% and 0.25% preparations are all Ecothiopate Eye Drops BNF.

Uses Chronic open-angle glaucoma. Chronic angle-closure glaucoma after iridectomy. Certain non-uveitic secondary types of glaucoma. Accommodative esotropia.

Dosage and administration *Early simple glaucoma:* Phospholine iodide 0.03% instilled twice daily; before retiring, and in the morning.

Advanced simple glaucoma and glaucoma secondary to cataract surgery: These cases may respond satisfactorily to Phospholine iodide 0.03% twice a day as above, but one of the higher strengths, 0.06%, 0.125% or 0.25%, may be needed. In this case, a brief trial with the 0.03% eyedrops will be advantageous in that the higher strengths will then be more easily tolerated. A single dose before retiring has been used, but twice daily is normal. More frequent dosage is undesirable. When a patient has been transferred from other therapy a brief trial with 0.03% may be useful.

Concomitant therapy: Phospholine iodide may be used concomitantly with adrenaline, a carbonic anhydrase inhibitor, or both.

Accommodative esotropia: In diagnosis: One drop 0.125% once daily in both eyes on retiring for two to three weeks. A favourable response may be noted within a few hours if the esotropia is accommodative.

In treatment: After initial period of treatment for diagnostic purposes, 0.125% every other day or 0.06% daily. Dosage can be lowered as treatment progresses. Maximum recommended dose 0.125% once daily.

Digital compression of the nasolachrymal ducts for a minute or two following instillation minimises drainage into the nasal chamber and hence reduces the incidence of any systemic side-effects.

Contra-indications, warnings, etc

Contra-indications: Most cases of angle-closure glaucoma. Active uveal inflammation. Hypersensitivity. Bronchial asthma.

Precautions: Pilocarpine eye drops should be administered for at least two months before initiating high-strength Phospholine iodide therapy in adults. The drops should be temporarily discontinued if (otherwise inexplicable) persistent diarrhoea, urinary incontinence, profuse sweating, muscle weakness or cardiac irregularities should occur. Anticholinesterase drugs should be used with extreme caution, if at all, in patients with bronchial asthma, marked vagotonia, peptic ulcer, pronounced bradycardia and hypotension, recent infarction, epilepsy, parkinsonism, etc. which may respond adversely to vagotonic effects. Anticholinesterase therapy should be avoided where there is a history of uveitis and used prior to ophthalmic surgery only as a considered risk because of the possible occurrence of hyphaema. While systemic effects are infrequent, digital compression of the naso-lachrymal ducts for a minute or so following instillation is necessary. The muscle relaxant succinylcholine should not be used prior to general anaesthesia in patients who are under treatment with 'Phospholine iodide', since cholinesterase inhibitors in general potentiate the effects of this drug. Caution should be observed in treating patients with myaesthesia gravis who are at the same time undergoing treatment with a systemic anticholinesterase. Phospholine iodide should be used with great caution, if at all, where there is a history of retinal detachment. The safety of anticholinesterase drugs in pregnancy has not been established.

1. Brow-ache, stinging, conjunctival reddening, and blurring due to accommodative spasm may occur when therapy is started but will disappear after 5–10 days of continuing treatment. Very few patients will be unable to tolerate the drug if reassurance is provided by the physician.

2. Lens opacities during Phospholine iodide therapy have been reported in adults, but the cause has not been established. Lens opacities have not been reported in adults following pilocarpine therapy or when using low-strength Phospholine iodide. Lens opacities have not been reported in children.

3. Iris cysts occur only occasionally in adults but fairly frequently in children. They usually do not interfere with continuation of treatment and will regress on reduction of dosage, or frequency of instillation.

4. Paradoxical increase in intra-ocular pressure may follow anticholinesterase instillation. This may be alleviated by prescribing a sympathomimetic, e.g. phenylephrine.

Accidental overdosage: Antidotes are atropine 2 mg parenterally; pralidoxime salts 25 mg/kg intravenously; artificial respiration should be given if necessary.

Pharmaceutical precautions Phospholine iodide has a shelf-life of 18 months in the dry form. After reconstitution the drops are stable for one month at room temperature or until the expiry date if kept in a refrigerator.

Legal category POM.

Package quantities Package for 5 ml of 0.03%. Package for 5 ml of 0.06%. Package for 5 ml of 0.125%. Package for 5 ml of 0.25%.

Further information Phospholine iodide is a potent, long-acting miotic which is both reliable and safe. It

offers a great advantage over short-acting miotics in that it continues to provide a protection against rising intra-ocular pressure during the night-time hours, which may otherwise lead to permanent retinal damage and narrowing of vision. The effects of 'Phospholine Iodide' are constant and stable, and the incidence of side-effects remarkably low once the dosage has been established.

PREMARIN* TABLETS

Presentation Premarin Tablets contain natural conjugated oestrogens.

Premarin Tablets 0.625 mg are maroon, oval, sugar-coated tablets printed 'Ayerst'.

Premarin Tablets 1.25 mg are yellow, oval, sugar-coated tablets printed 'Ayerst'.

Premarin Tablets 2.5 mg are purple, oval, sugar-coated tablets printed 'Ayerst'.

Uses Menopausal and post-menopausal oestrogen replacement therapy and allied disorders such as post-menopausal osteoporosis, atrophic vaginitis and post-menopausal atrophic urethritis. Functional amenorrhoea. Palliation of selected cases of breast cancer in women more than five years post menopausal. Inoperable prostatic carcinoma.

Dosage and administration *Menopausal and post-menopausal oestrogen deficiency:* Premarin 0.625–1.25 mg daily is the usual starting dose. Cyclic administration is recommended (three weeks' dosage followed by one week's rest). For maintenance the lowest effective dose should be used. If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day five of bleeding. In some cases the addition of a progestogen is advisable. When hormone replacement is contemplated, it is recommended that a complete physical examination including endometrial assessment, whenever possible, be performed at the time of the initial examination. The patient should be seen at 6 to 12 month intervals and the endometrium should be assessed regularly where possible. Any breakthrough bleeding is an indication for endometrial evaluation. Treatment should be discontinued prior to surgery if this entails a risk of thrombosis.

Atrophic vaginitis, kraurosis vulvae: 0.625–1.25 mg or more daily and cyclically depending on the response of the individual patient.

Post-menopausal osteoporosis: Cyclically 0.625–1.25 mg daily.

Functional Amenorrhoea: 1.25–3.75 mg daily in divided doses for 21 days. For the last seven days progestogen therapy should be added.

Breast cancer: In selected cases of mammary cancer oestrogens may be used for palliation in women who are at least five years post-menopausal. The suggested dose of Premarin is up to 10 mg three times a day for a period of at least three months.

Prostatic carcinoma: 3.75–7.5 mg daily in divided doses as palliative therapy.

Contra-indications, warnings, etc

Contra-indications: Uterine leiomyomata. Endometriosis. Cancer of the breast, uterus and other oestrogen dependent neoplasia. Hepatic, renal and severe cardiac disease. Undiagnosed genital bleeding. Pregnancy.

Although Premarin is a natural oestrogen in contrast to the synthetic preparations which may cause thrombosis, it should not be given to patients with a personal history of thrombosis or thromboembolic disease (including coronary thrombosis, cerebrovascular accident, etc).

Precautions: In the male – continuous therapy over prolonged periods of time may produce gynaecomastia, loss of libido and testicular atrophy. In the female – prolonged use of unopposed oestrogen may increase the risk of endometrial carcinoma.

Mastopathy.

Some women may develop cholelithiasis during oestrogen therapy.

When oestrogens are administered to patients with hypertension supervision is necessary and blood pressure should be monitored at regular intervals. In a diabetic patient for whom HRT is required Prempak should be considered in preference to unopposed oestrogen.

Because larger doses of oestrogen may increase thyroid binding globulin leading to increased circulating total thyroid hormone care should be taken in prescribing oestrogens for patients with thyrotoxicosis.

Side-effects: Although side-effects associated with Premarin tablets are extremely rare, the following may occur: Gastro-intestinal symptoms, headaches, breast tenderness, salt and water retention.

Overdosage: Reports of ingestion of large doses of oestrogen-containing products indicate that acute serious ill effects do not occur and overdosage is unlikely to be a problem.

Pharmaceutical precautions No special requirements for storage are required.

Legal category POM.

Package quantities

Premarin 0.625 mg: Bubble packs of 21 and Securitainers of 100.

Premarin 1.25 mg: Bubble packs of 21 and Securitainers of 100.

Premarin 2.5 mg: Securitainers of 100 tablets.

Further information Premarin is a mixture of natural oestrogens in the proportions physiologically maintained by nature. Unlike synthetic hormones Premarin is comparatively free from side-effects; in particular its effect on blood platelet behaviour is different from synthetic oestrogens. Amelioration of the individual's mental outlook, especially in the menopause, is generally associated with clinical improvement and is described by the patient as a gratifying sense of 'well being'.

Product licence numbers

Premarin Tablets 1.25 mg	0607/5001
Premarin Tablets 0.625 mg	0607/5000

PREMARIN* VAGINAL CREAM

Presentation Premarin Vaginal Cream contains 0.625 mg per gram of conjugated oestrogens in a non-liquefying base.

Uses Atrophic vaginitis and postmenopausal atrophic urethritis. Before and after urogenital surgery in the postmenopausal woman. Pruritis vulvae. Kraurosis vulvae.

Dosage and administration 1–2 g daily intravaginally or topically depending on the severity of the condition. A total daily dosage of 4 g should not be exceeded. The lowest dose that will control symptoms should be chosen. Administration should be cyclic (e.g. 3 weeks on and one week off). In postmenopausal surgery therapy is suggested 10 days before and 10 days following intervention.

If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day five of bleeding. When hormone replacement is contemplated, it is recommended that a complete physical examination including endometrial assessment, whenever possible, be performed at the time of the initial examination. Regular follow-up examinations, including endometrial assessments are recommended every 6–12 months. Breakthrough bleeding is an indication for medical evaluation.

Contra-indications, warnings, etc

Due to the possibility of systemic oestrogen absorption following the application of Premarin Vaginal Cream, prolonged administration might result in effects similar to those associated with prolonged use of Premarin Tablets. Therefore, the following contra-indications, precautions and possible side effects should be considered, although none of these have been reported directly with Premarin Vaginal Cream therapy.

Contra-indications: Uterine leiomyomata, endometriosis, cancer of the breast, uterus and other oestrogen dependent neoplasia, hepatic, renal and severe cardiac disease, undiagnosed genital bleeding, pregnancy.

Although Premarin is a natural oestrogen in contrast to the synthetic preparations which may cause thrombosis it should not be given to patients with a personal history of thrombosis or thromboembolic disease (including coronary thrombosis, cerebrovascular accident, etc.).

Precautions: Prolonged use of unopposed oestrogen may increase the risk of endometrial carcinoma.

Mastopathy.

Use in atrophic lesions of the vulva does not preclude the necessity for diagnostic measures to eliminate the possibility of neoplasia nor does it preclude the requirement for antimicrobial therapy in the presence of trichomonal, monilial or bacterial infection.

Some women may develop cholelithiasis during oestrogen therapy.

When oestrogens are administered to patients with hypertension supervision is necessary and blood pressure should be monitored at regular intervals.

In a diabetic patient insulin requirement may be altered.

Because larger doses of oestrogen may increase thyroid binding globulin leading to increased circulating total thyroid hormone, care should be taken in prescribing oestrogens for patients with thyrotoxicosis.

Side-effects: Although side-effects associated with Premarin Vaginal Cream are extremely rare, the following may occur: breast tenderness, headaches, salt and water retention, abnormal or excessive bleeding.

Overdosage: Reports of ingestion of large doses of oestrogen-containing products indicate that acute seri-

ous ill effects do not occur and overdosage is unlikely to be a problem.

Pharmaceutical precautions No special requirements for storage are necessary.

Legal category POM.

Package quantities Each pack contains 42.5 g of the non-liquefying cream with one calibrated applicator.

Further information Due to the low bulk of each application there is little likelihood of leakage.

Product licence number 0607/0005.

PREMPAK*

Presentation Prempak 0.625 contains 21 tablets natural conjugated oestrogens (Premarin) 0.625 mg plus 7 tablets norgestrel 0.5 mg.

Prempak 1.25 contains 21 tablets natural conjugated oestrogens (Premarin) 1.25 mg plus 7 tablets norgestrel 0.5 mg.

Uses For menopausal and postmenopausal oestrogen replacement therapy and allied disorders such as postmenopausal osteoporosis and senile vaginitis.

Dosage and administration *Menopausal and postmenopausal oestrogen deficiency:* Premarin 0.625 mg or 1.25 mg daily cyclically. One norgestrel tablet should be taken daily from day 15 to 21 of Premarin therapy. This should be followed by 7 tablet-free days. The pack carries patient instructions.

For maintenance, the lowest effective dose is recommended. If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If withdrawal bleeding is heavy, then the dose of Premarin may be reduced and periodical gynaecological examinations are advised for patients on long term therapy. In women with obesity, diabetes, low parity or a familial history of endometrial carcinoma, for whom hormone replacement therapy is required, Prempak should be considered in preference to unopposed oestrogen therapy. Prempak provides both oestrogens and a progestogen to restore endocrine balance, whilst avoiding endometrial hyperstimulation – this is achieved by endometrial shedding which occurs as a result of Prempak therapy. This also provides a form of cycle regulation in women who are still menstruating but irregularly. Before therapy commences it is recommended that the patient should have a complete physical examination.

Atrophic vaginitis: Premarin 0.625 mg – 1.25 mg daily for 21 days with 1 tablet norgestrel from day 15 to 21 of the cycle.

Postmenopausal osteoporosis: Premarin cyclically 0.625 mg to 1.25 mg daily on a 21-day cycle. 1 tablet norgestrel daily should be taken from day 15 to 21 of the Premarin cycle.

Contra-indications, warnings, etc

Contra-indications: Uterine leiomyomata. Endometriosis. Cancer of the breast, uterus and other oestrogen dependent neoplasia. Hepatic, renal and severe cardiac disease. Undiagnosed genital bleeding. Pregnancy. Although Premarin is a natural oestrogen in contrast to the synthetic preparations which may cause thrombosis, it should not be given to patients with a personal history

of thrombosis or thromboembolic disease (including coronary thrombosis, cerebrovascular accident, etc.).

Precautions: In a diabetic patient insulin requirement may be altered.

Mastopathy.

Some women may develop cholelithiasis during oestrogen therapy.

When oestrogens are administered to patients with hypertension supervision is necessary and blood pressure should be monitored at regular intervals.

Because larger doses of oestrogen may increase thyroid binding globulin leading to increased circulating total thyroid hormone, care should be taken in prescribing oestrogens for patients with thyrotoxicosis.

Prempak is not an oral contraceptive, neither will it restore fertility.

Side-effects: Although side-effects associated with Prempak are extremely rare, the following may occur: Gastrointestinal symptoms, headaches, breast tenderness, salt and water retention.

Overdosage: Reports of ingestion of large doses of oestrogen-containing products indicate that acute serious ill effects do not occur and overdosage is unlikely to be a problem.

Pharmaceutical precautions No special requirements for storage are required.

Legal category POM.

Package quantities Bubble pack of 21 Premarin tablets 0.625 mg or 1.25 mg plus 7 norgestrel tablets 0.5 mg.

Further information Prempak provides cycled oestrogen/progestogen therapy for the menopausal syndrome and associated disorders. The bubble pack contains 21 tablets of Premarin. From day 15 to day 21 inclusive each bubble contains in addition one norgestrel 0.5 mg tablet. The two tablets should be taken together for these seven days. The specially designed pack avoids the use of tablets containing more than one active compound.

Bayer UK Limited
Pharmaceutical Division
Burrell Road, Haywards Heath
West Sussex RH16 1TP

ADALAT*

Presentation *Adalat/Adalat 5*: Orange, soft gelatin capsules containing a yellow viscous liquid. Adalat capsules contain 10 mg nifedipine. Adalat 5 capsules contain 5 mg nifedipine.

Adalat Retard: Pink-grey lacquered tablets one side marked 1U, the reverse side with the Bayer Cross each containing 20 mg nifedipine.

Uses *Mode of action*: Adalat is a potent calcium antagonist. Its most important effect is to protect the heart against excessive oxygen utilisation during physical activity. There is a reduction in cardiac work and in myocardial oxygen demand. Adalat also causes peripheral vasodilatation and thus reduces peripheral resistance and heart work load. Adalat has no therapeutic anti-arrhythmic effect. Since Adalat does not cause a rise in intraocular pressure, it can be used in patients with glaucoma.

Indications: For the treatment and prophylaxis of angina pectoris and for the treatment of hypertension.

Dosage and administration For oral administration, the capsules should be taken with a little fluid during or after meals. The recommended dose is one 10 mg capsule three times daily. If necessary, up to two capsules three times daily may be taken.

If an immediate effect is required, the capsule should be bitten open and the liquid contents allowed to remain in the mouth.

Adalat 5 capsules permit titration of initial dosage in the elderly and those patients on concomitant medication. The recommended dose is one Adalat 5 capsules three times daily.

In the treatment of hypertension the recommended dose of Adalat Retard is one 20 mg tablet twice daily swallowed after food with a little fluid. If necessary the dose may be increased to 40 mg twice daily.

Treatment may be continued indefinitely.

Contra-indications, warnings, etc

Contra-indications: Must not be given to women capable of child-bearing.

Warnings and precautions: Adalat is not a beta-blocker and therefore gives no protection against the dangers of abrupt beta-blocker withdrawal; any such withdrawal should be by gradual reduction of the dose of beta-blocker, preferably over 8-10 days.

Adalat may be used in combination with beta-blocking drugs and other antihypertensive agents, but the possibility of an additive effect resulting in postural hypotension should be borne in mind. Adalat will not prevent possible rebound effects after cessation of anti-hypertensive therapy.

Adalat should be used with caution in patients whose cardiac reserve is poor.

Ischaemic pain has been reported in some patients, commonly within 30 minutes of the introduction of

Adalat therapy. Patients experiencing this effect should discontinue Adalat.

The use of Adalat in diabetic patients may require adjustment of their control. There is no known drug incompatibility.

Side-effects: Adalat is well tolerated. Minor side-effects, usually associated with vasodilatation are mainly headache, flushing and lethargy. These are transient and invariably disappear with continued treatment.

Overdosage: Standard measures such as atropine and noradrenaline may be used for resultant bradycardia and hypotension. Intravenous calcium gluconate may be of benefit.

Pharmaceutical precautions The capsules should be protected from strong light and stored in the manufacturer's original container.

Legal category POM.

Package quantities Adalat and Adalat 5 capsules are available in foil strips of 10 in packs of 100.

Adalat Retard tablets are also available in foil strips of 10 in packs of 100.

Further information As a specific calcium antagonist, Adalat's main action is to relax arterial smooth muscle both in the coronary and peripheral circulation.

In angina pectoris Adalat capsules relax peripheral arteries so reducing the load of the left ventricle. Additionally Adalat dilates submaximally both clear and atherosclerotic coronary arteries, thus protecting the heart against coronary artery spasm and improving perfusion to the ischaemic myocardium.

Adalat capsules reduce the frequency of painful attacks and the ischaemic ECG changes irrespective of the relative contribution from coronary artery spasm or atherosclerosis. In normotensive individuals Adalat has little or no effect on blood pressure.

In hypertension Adalat Retard twice daily provides smooth 24 hour control of raised blood pressure. Adalat Retard causes a reduction in blood pressure such that the percentage lowering of blood pressure is directly related to its initial height.

In long-term treatment, none of these formulations have been shown to cause serious adverse reactions. Metabolic disturbance, failure of ejaculation, increased incidence of Raynaud's phenomenon and bronchospasm associated with other anti-anginal and anti-hypertensive agents have not been observed.

Adalat Retard	PL0010/0078

ALRHEUMAT*

Presentation Opaque 'off-white' hard gelatin capsules

each containing 50 mg ketoprofen. Suppositories each containing 100 mg ketoprofen.

Uses Alrheumat is recommended for the management of the rheumatic diseases: rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, sero-negative (non-rheumatoid) arthropathies, non-articular rheumatism and soft tissue rheumatism.

Dosage and administration Alrheumat capsules are administered orally and should be taken with food. Dosage is usually 1 capsule (50 mg) three times daily. This dosage may be increased to 1 capsule four times daily or decreased to 1 capsule twice daily depending on the weight and clinical condition of the patient and the severity of the disease. As an alternative to oral therapy, one suppository should be inserted in the morning and before retiring. For the relief of night pain and morning stiffness, one suppository should be inserted before retiring. Combined oral and rectal therapy: one suppository should be inserted before retiring, supplemented during the day with Alrheumat capsules as needed, up to a maximum daily dosage of 200 mg ketoprofen. Paediatric usage has not been established.

Contra-indications, warnings, etc

Contra-indications: Ketoprofen should not be given to patients known to be sensitive to aspirin or to other non-steroidal anti-inflammatory agents which are prostaglandin inhibitors. In such patients, and in those with a history of bronchial asthma or allergic disease, severe broncho-spasm may be precipitated.

Ketoprofen should not be given to patients with active peptic ulceration.

The suppositories should not be used in patients with any inflammatory conditions of the rectum or anus.

Side-effects: Occasional gastro-intestinal disturbances occur and in some such cases a reduction in dosage has been helpful. In common with most other anti-inflammatory agents, there have been very rare reports of gastro-intestinal haemorrhage. Skin rashes have been rare.

Precautions: Patients with a history of peptic ulcer or chronic dyspepsia should be carefully monitored. Care should also be taken in patients with a history of impaired hepatic function. Alrheumat, in common with other propionic acid derivatives, exhibits moderate plasma protein binding. Patients receiving anticoagulants, hydantoins and protein-bound sulphonamides must therefore be closely monitored. The required dose of these drugs may well be beneficially reduced if taken concurrently with Alrheumat.

No embryotoxic or teratogenic effects have been reported, but, on principle, caution should be exercised when prescribing any new medication during pregnancy and lactation.

Pharmaceutical precautions The suppositories should be stored in a cool place.

Legal category POM.

Package quantities Alrheumat Capsules are available in blister strips of 10 packed in boxes of 100 and 500 capsules. Alrheumat suppositories available in blister strips of 10. Packed in boxes of 50.

Further information Nil.

Suppositories 0010/0066

BAYCARON*

Presentation A white scored tablet 7 mm × 2 mm, one side scored L/1, the reverse side with the Bayer cross, containing 25 mg mefruside.

Uses Baycaron is a diuretic agent and is intended for the treatment of hypertension and oedema.

Dosage and administration Baycaron is best taken with a little fluid as a single morning dose.

Oedema: Initially for 10–14 days, 25–50 mg every morning increasing if necessary to 75–100 mg to obtain the desired response. Daily doses in excess of 100 mg usually do not further increase diuresis.

For maintenance, and for long-term therapy, 25 mg each morning.

Alternate day dosage may also be used.

Hypertension: Initially for 10–14 days, 25–50 mg, then a maintenance dose of 25 mg each morning. Alternate day dosage may also be used.

Contra-indications, warnings, etc

Contra-indications: Severe hypokalaemia and hepatic coma.

Side-effects: Occasionally with daily doses up to 100 mg dyspepsia and nausea are encountered initially, but usually subside on continuing treatment. Patients with known sulphonamide sensitivity may show allergic reactions to Baycaron.

Overdosage: There is no special antidote or other action to be taken, since an adverse reaction is unlikely.

Precautions: As with other diuretics, during long-term treatment with Baycaron, potassium supplements may be necessary, especially for patients with impaired liver function, or for those also receiving cardiac glycosides. No teratogenic effect has been shown to be related to the use of Baycaron in animals or following its use in toxemia of pregnancy, but the benefits of the preparation should be weighed against the possible risks in the first trimester of pregnancy.

Pharmaceutical precautions There are no special precautions or requirements regarding the storage of Baycaron.

Legal category POM.

Package quantities Bottles of 150 tablets.

Further information Nil.

Product licence number 0010/5903.

BAYOLIN*

Presentation A white cream. Each 100 g cream contains heparinoid 'Bayer' 5,000 HDBu., glycoester of monosalicylic acid 10 g, benzyl nicotinate 2.5 g.

Uses Bayolin is a rubefacient used to treat all forms of muscular rheumatism, muscular stiffness due to exertion, lumbago, lumbar and cervical syndrome, local therapy of pains in muscles and joints due to rheumatic polyarthritis, arthroses and spondylosis deformans.

Dosage and administration Topical application two or three times daily, the cream being massaged gently into the affected area until absorbed.

Contra-indications, warnings, etc **Side-effects:** Occasionally a skin reaction to the nicotinic acid component of Bayolin may be seen.

Precautions: Bayolin is very well tolerated, but like any other rubefacient it can be very painful if it is allowed to get into the eyes, or come into contact with mucous membranes. It is advisable for the hands to be washed after application.

Pharmaceutical precautions There are no special requirements for storage or other precautions to be taken.

Legal category P.

Package quantities Bayolin Cream is available in 35 g tubes.

Further information Nil.

Product licence number 0010/5907.

BAYPEN*

Presentation Vials containing 0.5 g, 1 g, 2 g mezlocillin as mezlocillin sodium monohydrate. Infusion vials containing 5 g mezlocillin as mezlocillin sodium monohydrate. Baypen infusion sets containing 3 × 5 g mezlocillin, 3 × 50 ml Water for Injections and 3 transfer needles.

Uses Mezlocillin is a broad spectrum antibiotic indicated for the treatment of infections caused by sensitive organisms and prophylaxis of post-operative sepsis following abdominal surgery and vaginal hysterectomy.

The following Gram-positive and Gram-negative pathogens are sensitive to mezlocillin: *Escherichia coli*, species of the *Klebsiella-Enterobacter-Serratia* group, *Proteus* spp. (indole-positive and indole-negative), *Providencia* spp., *Citrobacter* spp., *Pseudomonas aeruginosa*, *Salmonella* spp. and *Shigella* spp., enterococci, staphylococci (penicillin sensitive), *Corynebacteria* and *Clostridium* spp. as well as *Bacteroidaceae*, in particular *Bacteroides fragilis*, *Haemophilus influenzae*, gonococci, meningococci, pneumococci and streptococci are particularly sensitive.

Mezlocillin is, therefore, indicated for the treatment of the following systemic and/or local infections in which the above-named organisms have been detected or are suspected: Septicaemia, infections of the urogenital tract (including gonorrhoea), respiratory and biliary tracts, meningitis, bone and soft tissue infections, peritonitis, infected wounds and burns, proven or suspected infections in patients with impaired or suppressed immunological status.

Mezlocillin may be administered concomitantly with an aminoglycoside antibiotic or with beta-lactamase stable isoxazolyl penicillins since there is evidence of synergy.

An aminoglycoside should not be mixed in the same syringe or intravenous fluid container as mezlocillin.

Dosage and administration Mezlocillin is normally given by the intravenous route but may be given intramuscularly if required.

Intravenous administration: Mezlocillin is prepared for injection by shaking the powder with a suitable volume of Water for Injections for 30–60 seconds until completely dissolved to make a 10% solution, i.e. 0.5 g in 5 ml, 1 g in 10 ml, 2 g in 20 ml and 5 g in 50 ml. A 10% aqueous solution is isotonic.

It is recommended that the 5 g strength is given by infusion over 15–20 minutes; all other strengths by bolus

injection over two to four minutes depending on the volume.

Intramuscular administration: Mezlocillin may be administered by the IM route if required as an alternative to the IV route (e.g. patients with poor veins). A single dose should not exceed 2 g, each 1 g of powder requiring 3.5 ml of water for injection to achieve complete solution.

Adults:

1. **Patients with normal renal function:** Life-threatening infections and infections due to unidentified organisms or *Pseudomonas* strains should be treated with 5 g, IV, six to eight hourly, by infusion over 15–20 minutes.

Non life-threatening infections due to sensitive organisms, and biliary and urinary tract infections, should be treated with 2 g, IV, six to eight hourly, as a bolus injection over two to four minutes.

If required, an intramuscular injection of 0.5–2 g may be given by deep injection into the buttocks in these cases.

For the treatment of acute gonorrhoea the dose is a single IM injection of 1 g.

Prophylactic dosage: 2.0 g i.v. to be given pre-operatively followed by two injections of 2.0 g post-operatively at eight hourly intervals.

2. **Patients with renal insufficiency:** These patients should receive the appropriate doses outlined above but at intervals of only 12 hours. Monitoring of the serum levels is recommended to ensure that adequate and constant levels are maintained.

Children: In the dosage schedule below the individual dose for premature babies and neonates is based on 75 mg/kg twice daily as a prolonged IV infusion and for infants and older children 3 × 75 mg/kg as bolus injection or short transfusion (IV).

Children over six years old, over 20 kg body weight: 1.5 g eight hourly.

Children two to six years old, 13–20 kg body weight: 1–1.5 g eight hourly.

Children one to two years old, 10–13 kg body weight: 0.75–1 g eight hourly.

Infants over three months, 5–10 kg body weight: 0.4–0.75 g eight hourly.

Infants up to three months, 3–5 kg body weight: 0.2–0.4 g eight hourly.

Infants and premature babies, below 3 kg body weight: 75 mg/kg body weight 12 hourly corresponding to 0.2 g 12 hourly.

Duration of treatment: The duration of treatment depends upon the severity of the case and also the clinical response and bacteriological findings. In principle, treatment should be carried out for at least three days after disappearance of clinical symptoms. Duration of treatment is usually 7–10 days.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity.

As with all new drugs mezlocillin should not be used during the first three months of pregnancy.

Side-effects: As for other penicillins.

Pharmaceutical precautions Mezlocillin should not be stored in temperatures exceeding 25°C.

Mezlocillin should be freshly prepared prior to administration, any unused solution being discarded.

Mezlocillin should be administered separately unless compatibility is proven.

Mezlocillin is compatible with dextrose 5% and 10%,

laevulose 5%, Ringer's Solution and physiological saline during the period of administration.

Legal category POM.

Package quantities Vials containing 0.5 g, 1 g, 2 g in boxes of 5 vials.

Vials of 5 g: single vials.

Baypen Infusion Packs of 3 × 5 g.

Further information Sodium content:

Each 5.0 g vial contains	9.27 mEq sodium (213.1 mg)
Each 2.0 g vial contains	3.71 mEq sodium (85.2 mg)
Each 1.0 g vial contains	1.85 mEq sodium (42.6 mg)
Each 0.5 g vial contains	0.93 mEq sodium (21.3 mg)

Product licence number 0010/0070

CANESTEN®

Presentation

- 1. Cream:** A white cream containing 1.0% clotrimazole.
- 2. Atomiser Spray:** A clear solution containing 1.0% clotrimazole in 30% isopropanol. The spray is produced by an atomiser and contains no propellant.
- 3. Solution:** A clear solution containing 1.0% clotrimazole in polyethylene glycol 400.
- 4. Powder:** A white powder containing 1.0% clotrimazole.
- 5. Vaginal Tablets:** White convex tablets, measuring 25 mm × 6.5 mm × 10 mm, 100 mg tablet marked 'BAYER' on one side and 'AD' on the other. 200 mg tablet marked 'BAYER' on one side and 'F9' on the other.

500 mg tablet (Canesten 1) marked 'Bayer' on one side and 'MU' on the other.

5. Vaginal Cream: A white cream containing 2.0% clotrimazole.

7. Duopak: A combination pack comprising 6 Canesten vaginal tablets (each containing 100 mg clotrimazole) plus a 20 g tube of Canesten cream (containing 1.0% clotrimazole).

indications Clotrimazole is a broad spectrum anti-fungal. It also exhibits activity against *Trichomonas*, *Streptococci* and *Bacteroides*. It has no effect on *Lactobacilli*:

- 1. Cream:** All fungal skin infections due to dermatophytes (e.g. *Trichophyton* species), yeasts (e.g. *Candida* species), moulds and other fungi. These include ringworm (tinea) infections, athlete's foot, paronychia, pityriasis versicolor, erythrasma, intertrigo, fungal nappy rash, candida vulvitis and candida balanitis.
- 2. Atomiser Spray:** As Canesten cream, recommended on infections covering large and/or hairy areas.
- 3. Solution:** The solution is particularly suitable for use on hairy skin and in fungal infections of the outer ear (otitis externa).
- 4. Powder:** As an adjunct to treatment with cream or atomiser spray and as a prophylactic against re-infection, particularly in infections such as athlete's foot. The powder should be applied to the lesions simultaneously and dusted inside articles of clothing in contact with infected areas.

5. Vaginal Tablets: Candida vaginitis and mixed vaginal infections where trichomonas is present or suspected. Canesten is not recommended as sole treatment for pure trichomoniasis, except in cases where systemic therapy is contra-indicated.

6. Vaginal Cream: As for (5) above.

7. Duopak: Vaginal tablets for candida vaginitis; cream for associated vulvitis and to treat the sexual partner to prevent re-infection.

Dosage and administration

1. Cream: Canesten cream should be thinly and evenly applied to the affected area two to three times daily, and rubbed in gently.

Treatment should be continued for at least one month, or for at least two weeks after the disappearance of all signs of infection (to prevent relapse).

If the feet are infected, they should be thoroughly washed and dried, especially between the toes, before applying the cream.

2. Atomiser Spray: As per Canesten cream.

3. Solution: as per Canesten cream.

4. Powder: Sprinkle on to the affected areas two to three times daily after using the cream or atomiser spray. The powder may also be dusted inside articles of clothing and footwear which are in contact with the infected area.

5. Vaginal Tablets 100 mg: Two vaginal tablets should be inserted daily, preferably at night, for three consecutive days. Alternatively, 1 vaginal tablet daily for six days may be given.

Vaginal Tablets 200 mg: One vaginal tablet should be inserted daily, preferably at night for three consecutive days.

Vaginal tablet 500 mg: (Canesten 1). The single tablet should be inserted at night.

Using the applicator provided, each vaginal tablet should be inserted as deeply as is comfortable into the vagina. This is best achieved when lying back with the legs bent up.

6. Vaginal Cream: insert one filled applicator (5 g) intravaginally twice daily for three consecutive days or once daily for six consecutive days preferably at night.

7. Duopak: 100 mg vaginal tablets as in 5, above. The cream should be applied night and morning to the vulva and surrounding area and/or to the sexual partner's penis to prevent re-infection.

Contra-indications, warnings, etc

Contra-indications: None known.

Side-effects: Rarely patients may experience local mild burning or irritation immediately after applying cream or atomiser spray or after inserting the vaginal tablet. Very rarely, the patient may find this irritation intolerable and stop treatment.

Precautions: Canesten atomiser spray should not be used near a naked flame, should not be allowed to come into contact with the eyes, ears or mucous membranes and should not be inhaled.

Pharmaceutical precautions Storage:

Cream – none.

Atomiser Spray – none.

Solution – none.

Powder – none.

Vaginal Tablets – none.

Vaginal Cream – none.

Duopak – none.

FABAHISTIN*

Presentation *Tablets*: orange-coloured sugar-coated tablets measuring approximately 8.5 mm × 5.5 mm, each tablet containing 50 mg mebhydrolin base.

Suspension: An orange-coloured suspension in a 100 ml glass bottle, each 5 ml suspension containing 50 mg mebhydrolin as mebhydrolin napadisylate.

Uses Fabahistin is an antihistamine recommended for the treatment of hay fever, urticaria, rhinitis and all other allergic disorders.

Dosage and administration Oral administration as follows:

Adults: 1 or 2 × 50 mg tablets three times a day.

Children: Over 10 years: 1 or 2 × 50 mg tablets three times a day.

Under 10 years: 1–4 × 5 ml spoonfuls of suspension daily, according to age, in divided doses after meals.

Contra-indications, warnings, etc

Contra-indications: None known.

Side-effects: Very rarely cases of granulocytopenia or agranulocytosis associated with the use of mebhydrolin have been reported.

Overdosage: No symptoms have been reported in a patient receiving 140 × 50 mg tablets.

Precautions: The substance may cause drowsiness. If affected, do not drive or operate machinery. Avoid alcoholic drinks.

No embryotoxic or teratogenic effects have been reported, but, on principle, caution should be exercised when prescribing any new medication during pregnancy and lactation.

Pharmaceutical precautions There are no special requirements for storage.

The suspension should not be diluted with water, but a suitable suspending agent should be used such as tragacanth. Suspensions to be stored for long periods should be diluted with a suspending agent containing methyl hydroxybenzoate BP 0.07 g, sodium carboxymethyl cellulose 0.5 g in 100 ml Purified Water BP.

Legal category P.

Package quantities Strip packs of 20 tablets. Bottles of 250 tablets. Bottles of 100 ml suspension.

Further information Nil.**Product licence numbers**

Suspension	0010/5915

LASONIL*

Presentation *Ointment*: A yellow-tinged transparent soft ointment contained in aluminium tubes. Each 100 g ointment contains heparinoid 'Bayer' 5,000 HDBu., hyaluronidase 15,000 i.u.

Uses Lasonil is a preparation containing heparinoid and hyaluronidase, which counteracts inflammation, promotes resorption of local oedema and extravasated blood, and locally delays blood clotting.

Ointment: Traumatic conditions: bruises, sprains, soft tissue injuries.

Varicose conditions: thrombophlebitis, superficial thrombosis, varicose ulcers.

Haemorrhoids.

Dosage and administration *Ointment*: *Traumatic conditions*: Unless otherwise directed, apply thickly and gently massage into the affected area two to three times daily.

Varicose conditions: In varicose ulcers Lasonil should be applied around the ulcer and gently massaged into the skin.

In thrombophlebitis and superficial thrombosis Lasonil should be massaged gently into the affected area three to five times daily.

Haemorrhoids: Apply night and morning, and after defaecation, to the anal region and inject a small quantity into the anal canal through the applicator.

There is no special dosage for children.

Contra-indications, warnings, etc *Contra-indications*: None.

Side-effects: None.

Precautions: Lasonil should not be applied to open or infected wounds.

Pharmaceutical precautions There are no special precautions or requirements regarding the storage, etc of Lasonil.

Legal category P.

Package quantities *Ointment*: Aluminium tubes containing 14 g and 40 g Lasonil.

Further information Nil.

Product licence number 0010/5914.

OSPOLOT®

Presentation *Tablets*: White lacquer-coated convex tablets 50 mg marked with Bayer Cross on one side and C4 on the other. 200 mg marked with the Bayer Cross on one side and the Letters 'F' and 'S' divided by a score mark on the other.

Suspension: A yellow/orange suspension contained in 100 ml and 500 ml glass bottles, each 5 ml of suspension containing 50 mg sulthiame.

Uses Ospolot is an anticonvulsant recommended for the treatment of grand mal, temporal lobe epilepsy, Jacksonian seizures, myoclonic attacks, hyperkinetic behaviour and disturbed behaviour associated with epilepsy, mental subnormality and psychiatric disorders.

Dosage and administration Oral administration as follows:

Adults: **Initial**: 100 mg twice daily.

Optimum: 200 mg three times daily.

Children: According to body weight:

Initial: 3–5 mg/kg daily in equal divided doses.

Optimum: 10–15 mg/kg daily in equal divided doses.

Contra-indications, warnings, etc

Contra-indications: None known, but caution should be exercised in patients with a history of renal disease.

Side-effects: These are usually mild and subside after 8–14 days. Paraesthesia of the extremities and face is the commonest. A usually transient hyperpnoea sometimes occurs unassociated with biochemical or cardiovascular changes. Gastric disturbances, headaches and vertigo have also been reported.

Where Ospolot is used in combination with phenytoin, it has been shown that there is a rise in phenytoin serum levels. This fact should be borne in mind when using this combination.

Overdosage: Crystalluria and renal damage are the main risks of overdosage with Ospolot. Alkaline fluid should therefore be administered, both orally and by intravenous infusion. Symptoms of overdosage are vomiting, severe headache, vertigo, ataxia and hyperventilation. Catatonia may develop; patients remain conscious.

Pharmaceutical precautions There are no special requirements for storage.

The suspension should not be diluted with water, but a suitable suspending agent should be used such as tragacanth. Suspensions to be stored for long periods should be diluted with a suspending agent containing methyl hydroxybenzoate BP 0.07 g, sodium carboxymethyl cellulose 1.0 g in 100 ml Purified Water BP.

Legal category POM.

Package quantities Bottles of 50 and 250 scored and lacquered tablets of 200 mg.

Bottles of 250 lacquered tablets of 50 mg.

Bottles of 500 ml suspension 50 mg/5 ml.

Further information Nil.

SECUROPEN®

Presentation Vials containing 0.5 g, 1.0 g, 2.0 g azlocillin as azlocillin monosodium. Infusion vials containing 5.0 g as azlocillin monosodium.

Securopen infusion set containing 3 × 5 g azlocillin, 3 × 50 ml Water for Injections and 3 transfer needles.

Uses Azlocillin is a broad spectrum antibiotic with especially significant anti-pseudomonal activity. In addition to *Pseudomonas* strains the spectrum of activity of azlocillin includes the following Gram-negative and Gram-positive pathogens: *Escherichia coli*, *Klebsiella Enterobacter Serratia* group, *Proteus* (indole-positive and indole-negative), *Providencia*, *Citrobacter*, *Salmonella* and *Shigella*, enterococci, staphylococci (penicillin sensitive), *Haemophilus influenzae*, gonococci, meningococci, pneumococci, streptococci and *Corynebacterium* spp. The spectrum also includes the anaerobic organisms *Clostridia* and *Bacteroides species*, including *Bacteroides fragilis*.

Azlocillin is specifically indicated for the treatment of infections due to *Pseudomonas* strains especially those of the respiratory and urinary tracts and for septicæmia. Also for infections in other areas due to this organism.

Azlocillin may be administered concomitantly with an aminoglycoside or with beta-lactamase stable isoxazolyl-penicillins, since there is evidence of synergy with these groups.

Dosage and administration *Adult Dosage*: **Patients with normal renal function**: Life-threatening infections 5.0 g every 8 hours. In non life-threatening and urinary tract infections 2.0 g every 8 hours.

Patients with severely impaired renal function: i.e. with a serum creatinine above 2 mg% or with creatinine clearance less than 30 ml/minute, the unit dose should be as above but at 12 hourly intervals.

Patients on haemodialysis: Azlocillin is dialysable. On non-dialysing days, patients receive the recommended unit dose of azlocillin twice daily. Before each dialysis an additional unit dose should be given to compensate for the amount of azlocillin removed by dialysis.

Children's Dosage:

Children 1–14 years	: 3 × 75 mg/kg bodyweight/day
Infants > 7 days–1 year	: 3 × 100 mg/kg bodyweight/day
Neonates < 7 days	: 2 × 100 mg/kg bodyweight/day
Premature babies	: 2 × 50 mg/kg bodyweight/day

From this the following dosages can be derived:

Children 6–14 years (20–40 kg bodyweight)	1.5–3.0 g 3 × daily
Children 2–6 years (13–20 kg bodyweight)	1.0–1.5 g 3 × daily
Children 1–2 years (10–13 kg bodyweight)	0.75–1.0 g 3 × daily
Infants 7 days–1 year (about 3–10 kg bodyweight)	0.3–1.0 g 3 × daily
Neonates 7 days (about 3 kg bodyweight)	0.3 g 2 × daily

Premature babies up to 2.5 kg bodyweight	2.5 kg bodyweight: 125 mg 2 × daily
	2.0 kg bodyweight: 100 mg 2 × daily
	1.5 kg bodyweight: 75 mg 2 × daily.

Duration of Treatment: The duration of treatment depends upon the severity of the case and also the clinical and bacteriological course of the disease. In principle, treatment should be maintained for at least 3 days after fever or clinical symptoms have disappeared. This on average requires 7–10 days therapy.

Administration: Azlocillin is administered intravenously as a 10% solution in Water for Injections. For doses of 2.0 g or less it is administered as a bolus injection and for higher doses as an infusion over 20–30 minutes. Aminoglycosides, when given concomitantly, should not be mixed in the same syringe or infusion fluid as azlocillin.

Combination Therapy: In patients already receiving intravenous infusion therapy with other drugs, azlocillin should be infused during the intervening periods or as a parallel infusion. In order to achieve higher initial concentrations in the serum and tissues, part of the dose – up to half – may be injected slowly through the tubing of the existing infusion. Azlocillin solution is compatible with glucose solution (5% and 10%), laevulose solution (5%), Ringer's solution and physiological saline. Supplementary drugs should be injected through the drip tubing and not introduced into the bag or bottle. Injectable tetracycline derivatives, for example, have proved to be incompatible. Before administering special, rarely used solutions or drugs the compatibility of the individual components must be ascertained; precipitation, cloudiness or discolouration indicates possible incompatibility.

Stability in other infusions: Azlocillin is stable in the common infusion fluids provided the solution has been freshly prepared. If azlocillin must be prepared before administration it may be kept as the 10% solution at room temperature for 6 hours without loss of efficacy.

Contra-indications, warnings, etc

Contra-indications: A history of allergy to other penicillins and cephalosporins. Securopen is inactivated by β -lactamases (penicillinases). As with all new drugs Securopen should not be used during the first 3 months of pregnancy.

Side-effects: Uncommon and typical for other injectable penicillins.

Toxicity and treatment of overdose: There have been no reports of toxic effects or overdosage.

Pharmaceutical precautions *Storage:* The shelf life is 4 years when stored below 25°C and expiry date is printed on the packaging. Azlocillin should not be stored in temperatures exceeding 25°C.

Dilution: Azlocillin should be freshly prepared immediately before administration by shaking the powder with a suitable volume of Water for Injections until completely dissolved to make a 10% solution – that is, 0.5 g in 5 ml, 1.0 g in 10 ml, 2.0 g in 20 ml and 5.0 g in 50 ml. Any unused solution should be discarded. Azlocillin is stable in 5% and 10% dextrose solution, laevulose 5%, Ringer's solution and physiological saline.

Legal category POM.

Package quantities 0.5 g, 1.0 g, 2.0 g vials packed in boxes of 5.
5.0 g vial packed singly.
Securopen infusion pack of 3 × 5 g.

Further information

Sodium content:	
Each 5.0 g vial contains	10.84 mEq sodium (249.1 mg)
Each 2.0 g vial contains	4.33 mEq sodium (99.6 mg)
Each 1.0 g vial contains	2.17 mEq sodium (49.8 mg)
Each 0.5 g vial contains	1.08 mEq sodium (24.9 mg)

Product licence number 0010/0075

TRASYLOL®

Presentation A colourless ampoule containing a solution of aprotinin for injection, each 5 ml ampoule containing 100,000 kallikrein inactivator units (KIU) and each 10 ml ampoule containing 200,000 KIU.

Uses Trasylol is a broad-spectrum protease inhibitor. Its indications are as follows:

Traumatic, haemorrhagic, pancreatogenic, endotoxin shock and fat-embolism syndrome.

Acute pancreatitis.

Prophylaxis in upper abdominal surgery.

Hyperfibrinolytic haemorrhage.

Dosage and administration *Traumatic, haemorrhagic, pancreatogenic, endotoxin shock and fat-embolism syndrome:* An initial 500,000 KIU should be administered immediately by slow i.v. injection (at a rate not exceeding 5 ml/min.) followed by 200,000 KIU four-hourly by i.v. infusion. It may be necessary to continue this dosage for three days or longer, depending on the clinical picture.

Acute pancreatitis: As above.

Prophylaxis in upper abdominal surgery: 200,000 KIU should be administered by slow i.v. injection immediately before commencing the operation. During the day of the operation, as well as during the first and second post-operative days, 200,000 KIU should be administered four-hourly by slow i.v. injection or continuous i.v. infusion.

Hyperfibrinolytic haemorrhage: Up to 500,000 KIU should be administered by slow i.v. injection within the first 30 minutes; subsequently 200,000 KIU four-hourly should be given by continuous i.v. infusion until haemostasis has definitely been achieved. In disseminated intravascular coagulation with secondary hyperfibrinolysis (consumption coagulopathy) higher dosages up to 1,000,000 KIU or more may be required. In fibrinogen deficiency substitution may be necessary.

The dose for children should be calculated in proportion to the adult dose on the basis of body weight.

Contra-indications, warnings, etc

Contra-indications: There are no contra-indications.

Side-effects: Trasylol is very well tolerated, even in high dosage. Local or general reactions are very rare (less than 0.1%). However, being a polypeptide, care should be exercised in treating patients intermittently or those who have previously received Trasylol, since an anaphylactic reaction can occur.

Trasylol is incompatible with most corticosteroids and nutrient solutions containing amino-acids or fat emulsions.

Overdosage: There is no special antidote or other action to be taken.

Pharmaceutical precautions Trasylol is very stable when stored in sealed ampoules at room temperature. Opened ampoules, however, quickly lose activity if bacterial contamination is not prevented.

Legal category POM.

Package quantities Trasylol is supplied in strengths of 100,000 KIU per 5 ml ampoule and 200,000 KIU per 10 ml ampoule in boxes of 5 and 25 ampoules.

Further information Nil.

Product licence number 0010/5900.

YOMESAN*

Presentation Yellowish tablets measuring 13 mm x 4 mm, each tablet containing 500 mg niclosamide BP. One side marked FE, the reverse side with the Bayer cross. The tablets are flavoured with vanilla.

Uses An anthelmintic for treatment of tapeworm infections:

<i>Taenia saginata</i>	(beef tapeworm)
<i>Taenia solium</i>	(pork tapeworm)
<i>Diphyllobothrium latum</i>	(fish tapeworm)
<i>Hymenolepis nana</i>	(dwarf tapeworm)

It has no effect in cysticercosis and echinococcosis due to cestode larvae (cysticerci) lodging in extra intestinal tissues.

Dosage and administration *Taenia saginata*, *Taenia solium*, *Diphyllobothrium latum*.

<i>Adults and children over 6 years:</i>	4 tablets
<i>Children 2 to 6 years:</i>	2 tablets
<i>Children under 2 years:</i>	1 tablet

In *Taenia solium* the tablets should be taken as a single dose after a light breakfast but in the case of *Taenia saginata* and *Diphyllobothrium latum* the dose may be divided, half being taken after breakfast and the remainder one hour later.

An aperient should be administered two hours later and in the case of *Taenia solium* a drastic purge should be given.

If reinfection occurs repeat treatment.

Infection due to *Hymenolepis nana* should be treated for 7 days:

First day:

<i>Adults and children over 6 years:</i>	4 tablets
<i>Children from 2 to 6 years:</i>	2 tablet
<i>Children under 2 years:</i>	1 tablets

The subsequent 6 days:

<i>Adults and children over 6 years:</i>	2 tablets
<i>Children from 2 to 6 years:</i>	1 tablet
<i>Children under 2 years:</i>	1/2 tablets

It is important that the tablets are chewed thoroughly before washing down with water. In the case of small children the tablets should be ground up before administration.

Contra-indications, warnings, etc

Contra-indications: there are no known contra-indications.

Side-effects: limited to occasional gastrointestinal upsets, light headedness and pruritus.

Overdosage: Yomesan is not absorbed and no cases of overdosage have occurred.

Use in Pregnancy: In common with most drugs it is wise to avoid treatment in the first trimester of pregnancy. Healthy children have been born to women treated with Yomesan in the first trimester of pregnancy.

Experimental studies in rats showed no embryotoxic or teratogenic effects.

Warning: In infections with *Taenia solium* there is always a danger of cysticercosis. A drastic purge is therefore recommended after treatment to eject the lower segment of the tapeworm containing mature eggs.

The hands should be thoroughly scrubbed after defaecation not only on the treatment day but for several days afterwards to avoid reinfection.

The consumption of alcohol during treatment must be avoided.

Pharmaceutical precautions The tablets are light sensitive and should only be stored in the original foil.

Legal category P.

Package quantities Packs of 4 tablets of 0.5 g.

Further information Unless the tapeworm is expelled by a drastic purgative, residual parts of it may be eliminated with the stools during the next two or three days. Thereafter, neither tapeworm segments nor ova should be present in the stools. In re-infection with *Taenia saginata* and *Taenia solium* new tapeworm segments or ova should only appear after three months.

In infections with *Hymenolepis nana* the follow-up period is only 14 days as surviving scolices regenerate very rapidly to sexually mature tapeworms and accordingly, after approx. 10 days, ova are eliminated with the stools.

Product licence number 0010/5910.

Middlesex TW8 9BD

AMPICLOX* INJECTION

Presentation *Ampiclox Injection*: Vials containing 250 mg ampicillin as Ampicillin Sodium BP with 250 mg cloxacillin as Cloxacillin Sodium BP.

Uses Ampiclox is indicated for the immediate treatment of severe infections before the infecting organism is identified, and for mixed staphylococcal and Gram-negative infections.

Typical indications include: Bronchopneumonia, post-influenzal pneumonia and other severe respiratory infections. Post-operative chest and wound infections. Septic abortions and infections during the puerperium. Septicaemia. Infections in patients receiving immunosuppressive drugs. Prophylaxis in major surgery.

Dosage and administration *Adult dosage: Intramuscular/Intravenous*: 1–2 vials four to six hourly.

Children's dosage: Up to 2 years: $\frac{1}{4}$ adult dose.†
2–10 years: $\frac{1}{2}$ adult dose.

Administration: Intramuscular: Dissolve vial contents in 1.5 ml Water for Injections BP.

Intravenous: Dissolve vial contents in 10 ml Water for Injections BP and administer slowly (three to four minutes). Ampiclox may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes.

Dosage may be further increased where necessary.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity; ocular administration.

Side-effects: As with other penicillins. An erythematous rash may occasionally occur, as with ampicillin. The incidence of this rash is particularly high in patients with infectious mononucleosis. If a rash is reported it is advisable to discontinue treatment.

Pharmaceutical precautions Ampiclox should be stored in a cool, dry place. Solutions for injection should be used immediately.

Ampiclox may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates). In intravenous solutions containing dextrose or other carbohydrates, Ampiclox should be infused within two hours.

Legal category POM.

Package quantities *Ampiclox Injection*: Boxes of 10.

Further information Nil.

Product licence number 0038/5003.

† Ampiclox Neonatal (regd) is recommended for the treatment of infections in neonates and premature babies.

**AMPICLOX* NEONATAL INJECTION
AMPICLOX* NEONATAL SUSPENSION**

Presentation *Ampiclox Neonatal Injection*: Vials containing 50 mg ampicillin as Ampicillin Sodium BP with 25 mg cloxacillin as Cloxacillin Sodium BP.

Ampiclox Neonatal Suspension: Bottles containing powder for the preparation of 10 ml suspension. When reconstituted each 0.6 ml dose contains 60 mg ampicillin as Ampicillin Trihydrate BP with 30 mg cloxacillin as Cloxacillin Sodium BP. A pipette to measure the 0.6 ml dose is provided.

Uses Ampiclox Neonatal is indicated for the prophylaxis or treatment of infections in premature babies or neonates, particularly:

Suspected or confirmed infections.

Babies born of mothers with infected liquor or whose membranes ruptured more than 48 hours before delivery.

Babies requiring certain surgical procedures carrying risk of infection such as exchange transfusions.

Babies born with respiratory distress necessitating endotracheal procedures, when subsequent infection is a possible hazard.

Babies following difficult delivery, when inhalation of much liquor, mucus or meconium has occurred.

Dosage and administration *Dosage: Oral*: 0.6 ml suspension (90 mg) every four hours.

Intramuscular/Intravenous: 1 vial (75 mg) three times a day.

Administration: Ampiclox Neonatal Injection:

Intramuscular: Dissolve vial contents in 0.5 ml Water for Injections BP.

Intravenous: Dissolve vial contents in 2 ml Water for Injections BP and administer slowly (three to four minutes). Ampiclox Neonatal may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes.

Contra-indications, warnings, etc

Contra-indications: Penicillin-hypersensitivity; ocular administration.

Caution should be observed when administering Ampiclox Neonatal to babies whose mothers are hypersensitive to penicillin.

Side-effects: As with other penicillins. An erythematous rash may occasionally occur, as with ampicillin. The incidence of this rash is particularly high in patients with infectious mononucleosis. If a rash is reported it is advisable to discontinue treatment.

Pharmaceutical precautions Ampiclox Neonatal should be stored in a cool, dry place.

Solutions for injection should be used immediately. Ampiclox Neonatal may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates). In intravenous solutions containing dextrose or other

carbohydrates, Ampiclox Neonatal should be infused within two hours.

Ampiclox Neonatal Suspension, once dispensed, should be kept in a refrigerator and used within five days.

Legal category POM.

Package quantities *Ampiclox Neonatal Injection:* boxes of 10.

mpiclox Neonatal Suspension: 10 ml bottles.

Further information Ampiclox Neonatal Suspension sugar-free to minimise the risks of diarrhoea in the newborn.

If tube feeding is necessary the suspension can easily be passed down a Ryle's tube.

Product licence numbers

mpiclox Neonatal Suspension 0038/5009

ANXON* CAPSULES ▼

Presentation Anxon Capsules: Dark pink/light pink capsules, in two sizes containing 15 mg or 30 mg citalopram overprinted with product name Anxon and its strength.

Uses *Action:* Anxon is a benzodiazepine and shares the general characteristics of this group of products.

Indications: Anxon is indicated for the treatment of anxiety, tension, irritability and similar stress related symptoms. Anxon also possesses muscle-relaxant properties and may be used in the management of spasticity associated with conditions such as spinal cord trauma, cerebrovascular accident and multiple sclerosis.

Dosage and administration *Usual Adult Dosage:* for most patients it is recommended that treatment should commence with a single dose of 30 mg, taken before retiring.

The effective dosage is usually in the range 15–60 mg per day, taken either as a single dose before retiring or in divided doses. When treating elderly or debilitated patients (e.g. those with cerebral disorders or cardio-respiratory insufficiency), a reduced dosage should be used initially until tolerance and efficacy have been assessed.

Patients undergoing therapy with centrally active products should be periodically reviewed.

Children: Insufficient data are available to recommend the administration of Anxon to children.

Contra-indications, warnings, etc

Precautions: The usual precautions when prescribing products of the benzodiazepine group should be observed.

Anxon may potentiate other centrally acting drugs such as alcohol, tranquillisers, anti-depressants, hypnotics, analgesics and anaesthetics.

Patients should be warned to exercise care when driving or operating heavy machinery, since drowsiness and modification of their reactions may occur depending on dosage and individual sensitivity.

Use cannot be recommended during pregnancy, labour or lactation.

Side-effects: Anxon is well tolerated; in comparative studies the overall incidence of side-effects was no greater than that observed with placebo.

As with other benzodiazepines daytime drowsiness has been reported.

Overdosage: Symptoms of overdosage may include drowsiness and ataxia, with coma in severe cases. The toxicity of the benzodiazepine group of drugs is very low, however, and symptomatic treatment only is required. Gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions Anxon capsules should be stored in well closed containers in a cool place.

Legal category POM.

Package quantities

Anxon Capsules: 15 mg – packs of 100.

30 mg – packs of 100.

Further information Anxon is particularly appropriate for those patients for whom a simple once daily dosage and a low incidence of side-effects are important considerations.

Anxon Capsules 30 mg 0038/0253

AUGMENTIN* TABLETS ▼

AUGMENTIN* DISPERSIBLE TABLETS ▼

Presentation *Augmentin Tablets:* White oval film coated tablets engraved 'AUGMENTIN' on one side. Each tablet contains potassium clavulanate equivalent to 125 mg clavulanic acid with amoxycillin trihydrate equivalent to 250 mg amoxycillin.

Augmentin Dispersible Tablets: White round tablets engraved 'AUGMENTIN'. Each tablet contains potassium clavulanate equivalent to 125 mg clavulanic acid with amoxycillin trihydrate equivalent to 250 mg amoxycillin.

Uses Augmentin is an antibiotic agent with a notably broad spectrum of activity against the commonly occurring bacterial pathogens in general practice and hospital. The novel action of clavulanate extends the spectrum of amoxycillin to embrace a wider range of organisms, including many resistant to other β -lactam antibiotics.

Augmentin is indicated for the short term oral treatment of common bacterial infections such as:

Upper Respiratory Tract Infections (including ENT) e.g. tonsillitis, sinusitis, otitis media.

Lower Respiratory Tract Infections e.g. acute and chronic bronchitis, lobar and bronchopneumonia.

Genito-urinary Tract Infections e.g. cystitis, urethritis, pyelonephritis, septic abortion, puerperal sepsis.

Other Infections e.g. skin and soft tissue infections, intra-abdominal sepsis, osteomyelitis.

Augmentin is bactericidal to a wide range of organisms including:

Gram-positive

Aerobes:

Streptococcus faecalis

Streptococcus pneumoniae

Streptococcus pyogenes

Streptococcus viridans

Staphylococcus aureus

Corynebacterium species

Bacillus anthracis

Listeria monocytogenes

Anaerobes:

Clostridium species
 Peptococcus species
 Peptostreptococcus

Gram-negative**Aerobes:**

Haemophilus influenzae
 Escherichia coli
 Proteus mirabilis
 Proteus vulgaris
 Klebsiella species
 Salmonella species
 Shigella species
 Bordetella pertussis
 Brucella species
 Neisseria gonorrhoeae
 Neisseria meningitidis
 Vibrio cholerae
 Pasteurella septica

Anaerobes:

Bacteroides spp.

Dosage and administration *Dosage: Adults and Children over 12 years:* One Augmentin or Augmentin Dispersible tablet (375 mg) three times a day. In severe infections this may be increased to two tablets three times a day. Treatment with Augmentin should not be extended beyond 14 days without review.

At present there is insufficient clinical evidence to permit a firm dosage recommendation to be made for younger children.

Administration: The absorption of Augmentin is unaffected by food.

Dispersible tablets should be stirred into a little water before taking.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Precautions: A number of studies at high dosages have shown Augmentin to be free from teratogenicity in animals; however, its safety in human pregnancy has not yet been established.

Renal impairment delays the excretion of clavulanate and amoxycillin but unless impairment is severe enough to require dialysis, no reduction of dosage is necessary. Each 375 mg tablet contains 0.63 m.mol of potassium.

Side-effects: Side-effects, as with amoxycillin, are uncommon and mainly of a mild and transitory nature.

Diarrhoea, indigestion, nausea, vomiting and candidiasis have been reported. Nausea, although uncommon, is more often associated with higher dosages. If gastrointestinal side-effects occur they may be reduced by taking Augmentin at the start of meals.

Urticarial and erythematous rashes sometimes occur but their incidence has been particularly low in clinical trials. Erythematous rashes have been associated with glandular fever in a few patients receiving amoxycillin. Treatment should be discontinued if either type of rash appears.

Pharmaceutical precautions Augmentin preparations should be stored in a dry place.

Bottles of Augmentin tablets should be kept tightly closed and the tablets should be dispensed in moisture-proof containers.

Legal category POM

Package quantities *Augmentin tablets:* Bottles of 30 and 100.

Augmentin Dispersible tablets: Foil wrapped in cartons of 30 and 90.

Further information Augmentin is a novel concept in antibiotic therapy.

Resistance to many antibiotics is caused by bacteria enzymes which destroy the antibiotic before it can act on the pathogen. The clavulanate in Augmentin anticipates this defence mechanism by blocking the β -lactamase enzymes, thus rendering the organisms sensitive to amoxycillin's rapid bactericidal effect at concentration readily attainable in the body. Clavulanate by itself has little antibacterial activity; however, in association with amoxycillin as Augmentin it produces a novel antibiotic agent of broad spectrum with wide application in hospital and general practice.

The pharmacokinetics of the two components of Augmentin are closely matched. Peak serum levels of both occur about 1 hour after oral administration. Both clavulanate and amoxycillin have low levels of serum binding; about 70% remains free in the serum.

Doubling the dosage of Augmentin approximately doubles the serum levels achieved.

BROXIL* CAPSULES**BROXIL* TABLETS****BROXIL* SYRUP**

Presentation *Broxil Capsules* (Phenethicillin Capsules BP): Black and ivory capsules overprinted 'Broxil' containing 250 mg phenethicillin as Phenethicillin Potassium BP.

Broxil Tablets (Phenethicillin Tablets BP): Yellow scored tablets engraved 'Broxil', containing 250 mg phenethicillin as Phenethicillin Potassium BP.

Broxil Syrup (Phenethicillin Elixir BP): Bottles containing powder for the preparation of 100 ml syrup.

When reconstituted each 5 ml contains 125 mg phenethicillin as Phenethicillin Potassium BP.

Uses Broxil is indicated for the oral treatment of infections caused by sensitive organisms. Typical indications include:

Ear, nose and throat infections: Tonsillitis, pharyngitis, sinusitis, laryngitis, otitis media, 'Strep' throat, dental abscess.

Respiratory tract infections: Acute bronchitis and lobar pneumonia.

Skin and soft tissue infections.

Dosage and administration *Adults:* 250 mg orally four times a day.

Children 2 to 10: $\frac{1}{2}$ adult dose.

Children under 2: $\frac{1}{4}$ adult dose.

Broxil should be given half to one hour before meals. Dosage may be doubled where necessary. Broxil Syrup may be diluted with Syrup BP.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Side-effects: As with other penicillins.

Pharmaceutical precautions Broxil should be stored in a cool, dry place.

Broxil Syrup when dispensed should be stored in a cool place and used within seven days.

Legal category POM.

Package quantities *Broxil Capsules and Tablets:* 100 capsules of 100.

Broxil Syrup: 100 ml bottles.

Further information Nil.

Product licence numbers

Broxil Tablets 0038/5020
Broxil Syrup 0038/0094

CELBININ* INJECTION

Presentation *Celbenin Injection* (Methicillin Injection BP 1973): Vials containing 1 g Methicillin Sodium BP 973.

Uses Celbenin is indicated for the treatment of infections suspected or confirmed to be caused by penicillinase-producing staphylococci.

Typical indications include: Respiratory tract infections. Skin and soft tissue infections. Osteomyelitis and septic arthritis. Staphylococcal urinary tract infections. Endocarditis. Meningitis.† Septicaemia.

Dosage and administration *Usual adult dosage:* Intramuscular: 1 g four to six hourly.

Intravenous: 1 g four to six hourly.

All recommended dosages are a guide only. In severe infections systemic dosages may be increased.

Intra-articular: 500 mg to 1 g once daily.

Intrapleural: 500 mg to 1 g once daily.

Subconjunctival: 500 mg once daily.

By nebuliser: 500 mg four times a day.

Usual children's dosage: 2–10 years: $\frac{1}{2}$ adult dose.

Under 2 years: $\frac{1}{4}$ adult dose.

Administration: *Intramuscular:* Dissolve 1 g in 1.5 ml Water for Injections BP.

Intravenous: Dissolve 1 g in 20 ml Water for Injections BP and give by slow injection (three to four minutes).

Celbenin may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes. Infusion bottles containing Celbenin should be changed every five hours.

Intra-articular: Dissolve 1 g in 5 ml Water for Injections BP or 0.5% lignocaine hydrochloride solution.

Intrapleural: Dissolve 1 g in 10 ml Water for Injections BP.

Subconjunctival: Dissolve 0.5 g in 0.5–0.75 ml of sterile water.

Nebuliser Solution: Dissolve 500 mg in 5 ml sterile water and administer by a suitable nebuliser.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity.

Side-effects: As with other penicillins.

Pharmaceutical precautions Celbenin should be kept in a cool, dry place.

Solutions should be used within 30 minutes of preparation.

Celbenin may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates).

Legal category POM.

Package quantities Celbenin vials are supplied in boxes of 10.

Further information Nil.

Product licence number 0038/5024.

FLOXAPEN* CAPSULES FLOXAPEN* SYRUP FLOXAPEN* INJECTION

Presentation *Floxapen Capsules* (Flucloxacillin Capsules BP): Black and caramel capsules overprinted 'Floxapen', containing 250 mg or 500 mg flucloxacillin as Flucloxacillin Sodium BP.

Floxapen Syrup (Flucloxacillin Elixir BP): Bottles containing powder for the preparation of 100 ml syrup. When reconstituted each 5 ml contains 125 mg flucloxacillin, as Flucloxacillin Sodium BP.

Floxapen Vials for Injection (Flucloxacillin Injection BP): Each vial contains 250 mg, 500 mg or 1 g flucloxacillin as Flucloxacillin Sodium BP.

Uses Floxapen is indicated for the treatment of infections due to Gram-positive organisms, including infections caused by penicillinase-producing staphylococci.

Typical indications include:

Skin and soft tissue infections: Boils. Abscesses. Carbuncles. Furunculosis. Cellulitis. Infected wounds. Infected burns. Protection for skin grafts. Otitis media and externa.

Infected skin conditions: e.g. ulcer, eczema and acne.

Respiratory tract infections: Pneumonia. Lung abscess. Empyema. Sinusitis. Pharyngitis. Tonsillitis. Quinsy.

Other infections caused by Floxapen-sensitive organisms: Osteomyelitis. Enteritis. Endocarditis. Urinary tract infection. Meningitis.† Septicaemia.

Dosage and administration *Usual adult dosage – Oral:* 250 mg four times a day.

Intramuscular: 250 mg four times a day.

Intravenous: 250–500 mg four times a day.

Systemic dosages may be doubled where necessary; oral doses should be administered a half to one hour before meals.

Intrapleural: 250 mg once daily.

By nebuliser: 125–250 mg four times a day.

Intra-articular: 250–500 mg once daily.

Usual children's dosage: 2–10 years: $\frac{1}{2}$ adult dose.

Under 2 years: $\frac{1}{4}$ adult dose.

Administration – Intramuscular: Dissolve 250 mg vial contents in 1.5 ml Water for Injections BP or 500 mg vial contents in 2 ml Water for Injections BP.

Intravenous: Dissolve 250–500 mg in 5–10 ml or 1 g in 15–20 ml Water for Injections BP. Administer by slow intravenous injection (three to four minutes). Floxapen may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes.

† *Intrathecal:* An intrathecal preparation and further information may be obtained from the Company's Medical Department.

Intrathecal: Consult the Company's Medical Department.

Intrapleural: Dissolve 250 mg in 5–10 ml Water for Injections BP.

Intra-articular: Dissolve 250–500 mg in up to 5 ml Water for Injections BP or 0.5% lignocaine hydrochloride solution.

Nebuliser Solution: Dissolve 125–250 mg of the vial contents in 3 ml sterile water.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity; ocular administration.

Side-effects: As with other penicillins.

Pharmaceutical precautions Floxapen should be stored in a cool, dry place.

Floxapen Syrup when dispensed should be stored in a cool place and used within seven days; it may be diluted with Syrup BP.

Solutions for IM and direct IV injection should normally be administered within 30 minutes of preparation. However, aqueous solutions of Floxapen retain their activity for up to 24 hours at room temperature (25°C) and for up to 72 hours in the refrigerator (5°C). If storage for this increased period is necessary, reconstitution should be carried out under appropriate aseptic conditions.

Floxapen may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates).

Legal category POM.

Package quantities *Capsules 250 mg:* Canisters of 20 and 100; bottles of 500.

Capsules 500 mg: bottles of 100.

Syrup 125 mg: 100 ml bottles.

Vials 250 mg, 500 mg: Boxes of 10.

Vials 1 g: Boxes of 5

Further information Floxapen has the same spectrum of activity as the earlier antistaphylococcal penicillins methicillin and cloxacillin against Gram-positive organisms, including penicillinase-producing strains. However, following oral administration Floxapen gives blood levels comparable with those achieved by intramuscular injection.

MAGNAPEN* CAPSULES

MAGNAPEN* SYRUP

MAGNAPEN* INJECTION

Presentation *Magnapen Capsules:* Black and turquoise capsules overprinted 'Magnapen', containing 250 mg ampicillin as Ampicillin Trihydrate BP with 250 mg flucloxacillin as Flucloxacillin Sodium BP.

Magnapen Vials for Injection: 500 mg Vial: containing 250 mg ampicillin as Ampicillin Sodium BP with 250 mg flucloxacillin as Flucloxacillin Sodium BP.

1 g Vial: containing 500 mg ampicillin as Ampicillin Sodium BP with 500 mg flucloxacillin as Flucloxacillin Sodium BP.

Magnapen Syrup: Bottles containing powder for the preparation of 100 ml suspension. When reconstituted

each 5 ml contains 125 mg ampicillin as Ampicillin Trihydrate BP with 125 mg flucloxacillin as Flucloxacillin Sodium BP.

Uses Magnapen is indicated for the treatment of severe infections where the causative organism is unknown, and for mixed infections involving 'resistant' staphylococci. Typical indications include:

In general practice: Chest infections, ENT infections, skin and soft tissue infections, and patients with an underlying pathology which makes them more susceptible to infection.

In hospital (prior to laboratory results being available): Severe respiratory infections. Post-operative chest and wound infections. Septic abortion; puerperal fever. Septicaemia. Prophylaxis in major surgery. Infections in patients receiving immuno-suppressive therapy.

Magnapen's spectrum also makes it suitable for the treatment of many mixed infections, particularly those where penicillinase-producing staphylococci are suspected or confirmed.

Dosage and administration *Oral: Adult:* 1 capsule or 10 ml syrup four times a day.

Children: Under 10 years: 5 ml syrup four times a day.†

Intramuscular/Intravenous: Adult: 500 mg four times a day.

2–10 years: $\frac{1}{2}$ adult dose. *Under 2 years:* $\frac{1}{4}$ adult dose.†

Dosage for adults and children may be doubled where necessary. Oral doses should be given a half to one hour before meals.

Administration: *Intramuscular:* 500 mg Vial: contents should be dissolved in 1.5 ml Water for Injections BP. 1 g Vial: contents should be dissolved in 2.0 ml Water for Injections BP.

Intravenous: Dissolve 500 mg Vial in 10 ml Water for Injections BP. Dissolve 1 g Vial in 20 ml Water for Injections BP. Administer by slow intravenous injector (3–4 minutes). Magnapen injection may be added to infusion fluids or injected, suitably diluted into the drip tube over a period of 3–4 minutes.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity; ocular administration.

Side-effects: As with other penicillins. An erythematous rash may occasionally occur, as with ampicillin. The incidence of this rash is particularly high in patients with infectious mononucleosis. If a rash is reported it is advisable to discontinue treatment.

Pharmaceutical precautions Magnapen should be stored in a cool, dry place.

Magnapen Syrup, when dispensed, should be stored in a cool place and used within seven days. It may be diluted with Syrup BP.

Magnapen solutions for injection should be used immediately.

Magnapen may be added to most intravenous fluid; but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates). In intravenous solutions containing dextrose or other carbohydrates, Magnapen should be infused within two hours.

† Ampiclox* Neonatal is recommended for the treatment of infections in neonates and premature babies.

Legal category POM.

Package quantities *Magnapen Capsules*: Canisters of 20 and 100.

Magnapen Syrup: 100 ml bottles.

Magnapen Injections: Boxes of 10 vials.

Further information Infections encountered in medical practice can be of mixed bacteriology, often including penicillinase-producing strains. Magnapen provides the broad spectrum of activity which should be considered when dealing with such infections.

MAXOLON* TABLETS**MAXOLON* SYRUP****MAXOLON* PAEDIATRIC LIQUID****MAXOLON* INJECTION**

Presentation *Maxolon Tablets*: (Metoclopramide tablets BP): Small, white, scored tablets, engraved Maxolon. Each tablet contains Metoclopramide Hydrochloride BP equivalent to 10 mg of the anhydrous substance.

Maxolon Syrup: Clear yellow lemon/lime solution. Each 5 ml dose contains Metoclopramide Hydrochloride BP equivalent to 5 mg of the anhydrous substance.

Maxolon Paediatric Liquid: Clear, yellow, lemon/lime flavoured solution, in a bottle with a 1 ml pipette. Each 5 ml contains Metoclopramide Hydrochloride BP equivalent to 1 mg of the anhydrous substance.

Maxolon Ampoules (Metoclopramide Injection BP): Clear, colourless solution. Each 2 ml ampoule contains Metoclopramide Hydrochloride BP equivalent to 10 mg of the anhydrous substance.

Uses *Digestive disorders*: Maxolon restores normal co-ordination and tone to the upper digestive tract and relieves symptoms of gastro-duodenal dysfunction including:

Dyspepsia. Flatulence. Heartburn. Regurgitation of bile. Sickness. Pain. – associated with such conditions as:

peptic ulcer. Reflux oesophagitis. Gastritis. Duodenitis. Hiatal hernia. Cholelithiasis and post-cholecystectomy dyspepsia.

Nausea and vomiting: Maxolon is indicated for the treatment of nausea and vomiting associated with:

Gastro-intestinal disorders. Cyclical vomiting. Intolerance to essential drugs including digitalis, antibacterial and cytotoxic drugs. Congestive heart failure. Deep X-ray or cobalt therapy. Post-anaesthetic vomiting.

Migraine: Maxolon relieves symptoms of nausea and vomiting, and overcomes gastric stasis associated with attacks of migraine. This improvement in gastric emptying assists the absorption of concurrently administered oral anti-migraine therapy (e.g. paracetamol) which may otherwise be impaired in such patients.

Post-operative conditions: Post-operative gastric hypomotility. Post-vagotomy syndrome. Maxolon promotes normal gastric emptying and restores motility in vagotomised patients, and where post-operative symptoms suggest gastro-duodenal dysfunction.

Diagnostic procedures: Radiology. Duodenal intubation.

Maxolon speeds up the passage of a barium meal by decreasing gastric emptying time, co-ordinating peristalsis and dilating the duodenal bulb. Maxolon also facilitates duodenal intubation procedures.

Dosage and administration Total daily dosage of Maxolon, especially for children and young adults, should not normally exceed 0.5 mg/kg bodyweight.

Medical indications:**Oral:****Adults:**

Young adults 15–20 years

10 mg three times daily
5–10 mg three times daily, commencing at the lower dosage.

Children

Maxolon should only be used after careful examination to avoid masking an underlying disorder, e.g. cerebral irritation. The following dosage recommendations should be strictly adhered to if side-effects of the dystonic type are to be avoided.

Accurate dosage is facilitated by the use of the paediatric liquid. Tablets should not be used in children under the age of 15: more accurate dosing can be obtained using the liquid presentations for the younger age groups.

5–14 years: 2½–5 mg three times daily.

3–5 years 2 mg two to three times daily.

1–3 years 1 mg two to three times daily.

Under 1 year 1 mg twice daily.

Treatment of children should commence at the lower dosage.

IM or IV:

Maxolon may be administered at the dosages stated above.

Diagnostic indications:

A single dose of Maxolon may be given 5–10 minutes before the examination.

Adults (over 15 years) 10–20 mg

Children 5–14 years 2½–5 mg

3–5 years 2 mg

Under 3 years 1 mg

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Maxolon.

If vomiting persists the patient should be re-assessed to exclude the possibility of an underlying disorder, e.g. cerebral irritation.

Various extrapyramidal reactions to Maxolon, usually of the dystonic type, have been reported. The incidence of these reactions in children and young adults may be increased if daily dosages higher than 0.5 mg/kg body weight are administered. Reactions include: spasm of the facial muscles, trismus, rhythmic protrusion of the tongue, a bulbar type of speech, spasm of extra-ocular muscles including oculogyric crises, unnatural positioning of the head and shoulders and opisthotonos. There

may be a generalised increase in muscle tone. The majority of reactions occur within 36 hours of starting treatment and the effects usually disappear within 24 hours of withdrawal of the drug. Should treatment of a reaction be required, an anticholinergic anti-Parkinsonian drug or a benzodiazepine may be used. Since extrapyramidal symptoms may occur with both Maxolon and phenothiazines, care should be exercised in the event of both drugs being prescribed concurrently.

Raised serum prolactin levels have been observed during metoclopramide therapy; this effect is similar to that noted with many other compounds.

Maxolon's action on the gastro-intestinal tract is antagonised by anticholinergics.

Although animal tests in several mammalian species have shown no teratogenic effects, treatment with Maxolon is not advised during the first trimester of pregnancy.

Following operations such as pyloroplasty or gut anastomosis Maxolon therapy should be withheld for three or four days as vigorous muscular contractions may not help healing.

Pharmaceutical precautions Maxolon Syrup must be protected from light and should be dispensed into amber glass containers. It may be diluted with Purified Water BP but should not be stored diluted for long periods.

Both Syrup and Paediatric Liquid should be stored in a cool place, and the Paediatric Liquid, once dispensed, should be used within 14 days.

If ampoules are removed from their carton, they should be stored away from light. If inadvertent exposure occurs, ampoules showing a yellow discoloration must be discarded.

Legal category POM.

Package quantities *Tablets:* Canisters of 100 and 500.

Syrup: Bottles of 200 ml and 1 litre.

Paediatric Liquid: 15 ml bottles with 1 ml pipette.

Ampoules: Boxes of 10.

Further information Maxolon's action is closely associated with parasympathetic nervous control of the upper gastro-intestinal tract, where it has the effect of encouraging normal peristaltic action. This provides for a fundamental approach to the treatment of those conditions where disturbed gastro-intestinal motility is a common underlying factor.

The absorption of any concurrently administered oral medication may be modified by the normalising effect of Maxolon.

The IV use of Maxolon 'High Dose' (100 mg in 20 ml) in the treatment of nausea and vomiting associated with cytotoxic drugs is the subject of a separate Data Sheet available from the Company.

ORBENIN* CAPSULES ORBENIN* SYRUP ORBENIN* INJECTION

Presentation *Orbenin Capsules* (Cloxacillin Capsules BP): Orange and black capsules overprinted 'Orbenin',

containing 250 mg or 500 mg cloxacillin as Cloxacillin Sodium BP.

Orbenin Syrup (Cloxacillin Elixir BP): Bottles containing powder for the preparation of 100 ml syrup.

When reconstituted each 5 ml contains 125 mg cloxacillin as Cloxacillin Sodium BP.

Orbenin Vials for Injection (Cloxacillin Injection BP): Each vial contains 250 mg, 500 mg or 1 g cloxacillin as Cloxacillin Sodium BP.

Uses Orbenin is indicated for the treatment of infections caused by Gram-positive organisms, including infections caused by penicillinase-producing staphylococci.

Typical indications include:

Skin and soft tissue infections: Boils. Abscesses. Carbuncles. Furunculosis. Cellulitis. Infected wounds. Infected burns. Protection for skin grafts. Otitis media and externa.

Infected skin conditions, e.g. ulcer, eczema and acne.

Respiratory tract infections: Pneumonia. Lung abscess. Empyema. Sinusitis. Pharyngitis. Tonsillitis. Quinsy.

Other infections caused by Orbenin-sensitive organisms: Osteomyelitis. Enteritis. Endocarditis. Urinary tract infection. Meningitis.† Septicaemia.

Dosage and administration *Usual adult dosage:*

Oral: 500 mg four times a day.

Intramuscular: 250 mg four to six hourly.

Intravenous: 500 mg four to six hourly.

Systemic dosages may be doubled where necessary: oral dosages should be administered half to one hour before meals.

Intrapleural: 500 mg once daily.

Intra-articular: 500 mg once daily.

By nebuliser: 125–250 mg four times a day.

Usual children's dosage:

2–10 years: $\frac{1}{2}$ adult dose.

Under 2 years: $\frac{1}{4}$ adult dose.

Administration: Intramuscular: Dissolve 250 mg in 1.5 ml Water for Injections BP.

Intravenous: Dissolve 500 mg in 10 ml or 1 g in 15–20 ml Water for Injections BP. Administer by slow intravenous injection (three to four minutes). Orbenin may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes.

Intrapleural: Dissolve 500 mg in 5–10 ml Water for Injections BP.

Intra-articular: Dissolve 500 mg in up to 5 ml Water for Injections BP or 0.5% lignocaine hydrochloride solution.

Nebuliser Solution: Dissolve 125–250 mg of the vial contents in 3 ml sterile water and administer by a suitable nebuliser.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity; ocular administration.

Side-effects: As with other penicillins.

Pharmaceutical precautions Orbenin should be stored in a cool, dry place.

Orbenin Syrup when dispensed should be stored in a cool place and used within seven days: it may be diluted with Syrup BP.

Solutions for IM and direct IV injection should normally be administered within 30 minutes of preparation.

† *Intrathecal:* An intrathecal preparation and further information may be obtained from the Company's Medical Department.

however, aqueous solutions of Orbenin retain their activity for up to 24 hours at room temperature (25°C) and for up to 72 hours in the refrigerator (5°C). If storage or this increased period is necessary, reconstitution should be carried out under appropriate aseptic conditions.

Orbenin may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates).

Legal category POM.

Package quantities Capsules 250 mg or 500 mg: Canisters of 50 and 250.

Vials 250 mg or 500 mg: Boxes of 10.

Vials 1 g: Box of 100.

Syrup: 100 ml bottles.

Further information Nil.

'ARAMAX' ▼

Presentation *Paramax Tablets*: White, round scored tablets, engraved 'Paramax' on one side.

Paramax Sachets: Sachets containing effervescent powder.

Each tablet or sachet contains 500 mg Paracetamol BP with Metoclopramide Hydrochloride BP equivalent to 5 mg of the anhydrous substance.

Uses *Indications*: Paramax is indicated for the symptomatic treatment of migraine.

Action: Paracetamol relieves pain. More rapid absorption; promoted by the action of metoclopramide which also relieves gastric stasis and overcomes nausea and vomiting.

Dosage and administration For oral administration only.

Paramax should be taken at the first warning of an attack. If symptoms persist, further doses may be taken at four-hourly intervals. Total dosage in any 24-hour period should not exceed the quantity stated.

Usual Recommended Dosage (Tablets or Sachets)

	Initial dose at first warning of attack	Maximum dosage in any 24-hour period
Adults	2	6
Young Adults (15–20 years)	1 or 2	5
Adolescents (12–14 years)	1	3

Children: A presentation of Paramax suitable for the treatment of children under 12 years of age is not available.

Note: Total daily dosage of metoclopramide should not exceed 0.5 mg/kg body weight.

Paramax Sachets: The contents should be emptied into about $\frac{1}{4}$ of a tumbler of water and stirred before taking.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Paramax.

If vomiting persists the patient should be re-assessed to exclude the possibility of an underlying disorder, e.g. cerebral irritation.

Various extra-pyramidal reactions to metoclopramide, usually of the dystonic type, have been reported. The incidence of these reactions may be increased if the metoclopramide dosage exceeds 0.5 mg/kg body weight/day. Reactions include: spasm of the facial muscles, trismus, rhythmic protrusion of the tongue, a bulbar type of speech, spasm of extra-ocular muscles, including oculogyric crises, unnatural positioning of the head and shoulders and opisthotonos. There may be a generalised increase in muscle tone. The majority of reactions occur within 36 hours of starting treatment and the effects usually disappear within 24 hours of withdrawal of the drug. Should treatment of a reaction be required, a benzodiazepine or an anticholinergic anti-Parkinson drug may be used.

Care should be exercised in the event of Paramax being prescribed concurrently with a phenothiazine since extra-pyramidal symptoms may occur with both products. The action of metoclopramide on the gastrointestinal tract is antagonised by anticholinergics.

Raised serum prolactin levels have been observed during metoclopramide therapy; this effect is similar to that noted with many other compounds.

There is no evidence that metoclopramide by itself has teratogenic effects; however, treatment with Paramax is not advised during the first trimester of pregnancy.

As with other paracetamol-containing products, an overdose of Paramax can be toxic to the liver. Overdosage should be treated by gastric lavage with appropriate supportive measures. Intravenous N-acetylcysteine or oral methionine if administered within 10 hours of paracetamol overdosage appears to exert a protective effect on the liver.

Pharmaceutical precautions Protect tablets from light. Store sachets in a dry place.

Legal category POM.

Package quantities *Paramax tablets*: bottles of 100. *Paramax sachets*: cartons of 30.

Further information An acute attack of migraine is frequently characterised by impaired absorption of analgesics even when abdominal symptoms are absent. The beneficial effect of Paramax on delayed gastric emptying, nausea and vomiting contrasts with the gastric stasis which may occur following administration of phenothiazine or antihistamine antiemetics.

Paramax Sachets 0038/0257

PAYNOCIL*

Presentation *Appearance*: Flat, circular, white, scored tablet embossed on one side with the product name PAYNOCIL.

Active ingredients: Each tablet contains:

Aspirin (acetylsalicylic acid)	600 mg
Glycine (aminoacetic acid)	300 mg

Uses *Principal action*: Aspirin is an analgesic, and antipyretic.

The glycine content allows the tablet to disperse instantly on the tongue and be rapidly distributed into the stomach in the finest glycine-coated particles; the risk of gastric irritation is therefore minimised.

Uses: Pain and Febrile conditions in which aspirin is indicated.

Rheumatoid Arthritis and other rheumatic conditions in which high and sustained dosage with plain aspirin tablets may increase the risk of intolerance.

Dosage and administration Paynocil should be taken orally. It can be taken without water as the lemon flavoured glycine coating of the particles masks the unpleasant taste of aspirin.

Adult dosage using Paynocil Tablets: As Paynocil contains 600 mg aspirin per tablet it is twice the strength of Aspirin Tablets BP and in equivalent dosage is twice as rapidly absorbed.

Analgesic/antipyretic: 1 tablet, every four to six hours if required.

In Rheumatoid Arthritis: for the treatment of early and recurrent rheumatoid arthritis, it is recommended that 2–3 tablets should be taken three times a day for two to three weeks. When the patient responds, the dosage should be reduced to 1–2 tablets three times a day as a maintenance dose.

Do not exceed the stated dose.

Contra-indications, warnings, etc

Contra-indications: Paynocil should not be given when aspirin is contra-indicated: e.g. hypersensitivity, peptic ulceration, haemophilia.

Warnings and precautions: Aspirin may enhance the effects of anti-coagulants, inhibit the action of uricosurics and precipitate attacks of asthma in susceptible individuals. As aspirin is a prostaglandin inhibitor and may affect blood clotting, therapy should ideally be withheld at term and during labour.

Side-effects: Aspirin may induce gastro-intestinal haemorrhage (occasionally severe). Gastric irritation, however, is minimised with Paynocil as the aspirin particles are coated with glycine.

Overdosage: Irrespective of the reported time interval since ingestion, gastric aspiration and lavage should be performed. Blood must be taken for plasma salicylate estimation. Forced alkaline diuresis may be needed.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities 18 tablets in foil strips of 6; 240 tablets in foil strips of 6.

Further information Paynocil is rapidly absorbed and well tolerated. It is easy to take because of its palatable lemon flavour.

Product licence number 0038/5081.

PENBRITIN* CAPSULES
PENBRITIN* SYRUP
PENBRITIN* SYRUP FORTE
PENBRITIN* PAEDIATRIC SUSPENSION
PENBRITIN* PAEDIATRIC TABLETS
PENBRITIN* INJECTION

Presentation *Penbritin Capsules* (Ampicillin Capsules BP): black and red capsules overprinted 'Penbritin', containing 250 mg or 500 mg ampicillin as Ampicillin Trihydrate BP.

Penbritin Syrup (Ampicillin Mixture BP): Bottles containing powder for the preparation of 100 ml cream coloured suspension. When reconstituted each 5 ml contains 125 mg ampicillin as Ampicillin Trihydrate BP.

Penbritin Syrup Forte (Strong Ampicillin Mixture BP) Bottles containing powder for the preparation of 100 ml cream-coloured suspension. When reconstituted each 5 ml contains 250 mg ampicillin as Ampicillin Trihydrate BP.

Penbritin Paediatric Suspension: Bottles containing powder for the preparation of 25 ml pink-coloured suspension. When reconstituted each 1.25 ml contains 125 mg ampicillin as Ampicillin Trihydrate BP. A pipette to measure the 1.25 ml dose is provided.

Penbritin Paediatric Tablets (Ampicillin Tablets BPC) Flavoured, off-white, scored tablets engraved 'Penbritin' Each tablet contains 125 mg ampicillin as Ampicillin Trihydrate BP.

Penbritin Vials for Injection (Ampicillin Sodium BP for Injection): Each vial contains 250 mg or 500 mg ampicillin as Ampicillin Sodium BP.

Uses Penbritin is a broad-spectrum penicillin, indicated for the treatment of a wide range of bacterial infection caused by most commonly occurring pathogens.

Typical indications include: Ear, nose and throat infections. Bronchitis. Pneumonia. Urinary tract infections. Gonorrhoea. Gynaecological infections. Septicaemia. Peritonitis. Endocarditis. Meningitis. Enteric fever. Gastro-intestinal infections. Or any other infection caused by Penbritin-sensitive organisms.

Penbritin is also indicated for the prevention of surgical infections by extraperitoneal application to wounds.

Dosage and administration *Usual adult dosage* (Oral except where stated):

Ear, nose and throat infections: 250 mg four times a day.
Bronchitis: Routine therapy: 250 mg four times a day.

High-dosage therapy: 1 g four times a day.
Pneumonia: 500 mg four times a day.

Urinary tract infections: 500 mg three times a day.
Gonorrhoea: 2 g orally with 1 g probenecid as a single dose. Repeated doses are recommended for the treatment of females.

Gastro-intestinal infections: 500–750 mg three to four times daily.

Enteric: Acute: 1–2 g four times a day for two weeks.

Carriers: 1–2 g four times a day for four to twelve weeks.

Septicaemia, endocarditis, osteomyelitis: 500 mg four to six times a day i.m. or i.v. for one to six weeks.

Peritonitis, intra-abdominal sepsis: 500 mg four times a day i.m. or i.v.

Meningitis: Adult dosage: 2 g six-hourly i.v. for two days. 500 mg to 1 g six-hourly i.m. from third day onwards. *Children's dosage:* 150 mg/kg daily i.v. for two days in divided doses. 100 mg/kg daily in divided doses from third day onwards. (Intrathecal therapy may be given concurrently – see below.)

Usual children's dosage (under 10 years): $\frac{1}{2}$ adult routine dosage.

All recommended dosages are a guide only. In severe infections dosages may be increased, or Penbritin given by injection. Oral doses of Penbritin should be taken half an hour before meals.

Administration: *Oral:* Capsules, Syrups, Paediatric Suspension or Paediatric Tablets.

Intramuscular: Dissolve 250 mg or 500 mg in 1.5 ml Water for Injections BP.

Intravenous: 250 mg dissolved in 5 ml or 500 mg in 10 ml Water for Injections BP given by slow injection (three to four minutes). Penbritin may also be added to infusion fluids or injected, suitably diluted, into the drip tube over a period of three to four minutes.

Intraperitoneal: At least 500 mg per 10 ml Water for Injections BP daily.

Intrapleural: 500 mg daily in 5–10 ml Water for Injections BP.

Intra-articular: 500 mg daily, dissolved in up to 5 ml Water for Injections BP or 0.5% procaine hydrochloride solution.

Intrathecal: An intrathecal preparation and further information may be obtained from the Company's Medical Department.

Local use in surgery: 1 g sterile powder sprinkled into the wound extraperitoneally or into muscle layers to prevent wound infection post-operatively.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity.

Side-effects: Side-effects, as with other penicillins, are rare and usually of a mild, transitory nature. Two types of rashes have been observed: an urticarial rash which is usually indicative of true penicillin hypersensitivity and an erythematous rash which is generally specific to ampicillin. The incidence of this erythematous rash is particularly high in patients with infectious mononucleosis. If a rash is reported it is advisable to discontinue treatment.

Pharmaceutical precautions Penbritin should be stored in a cool dry place.

Penbritin Syrup and Suspension, when dispensed, should be stored in a cool place and used within seven days: the syrups may be diluted with Syrup BP.

Penbritin solutions for injection should be used immediately.

Penbritin may be added to most intravenous fluids but should not be mixed with blood products or other proteinaceous fluids (e.g. protein hydrolysates). In intravenous solutions containing dextrose or other carbohydrates, Penbritin should be infused within one hour of preparation.

Legal category POM.

Package quantities *Penbritin Capsules* 250 mg: Canisters of 20, 100 and 500.

Penbritin Capsules 500 mg: Canisters of 20 and 100.

Penbritin Vials for Injection 250 mg, 500 mg: Boxes of 10.

Penbritin Syrup and Syrup Forte: 100 ml bottles.

Penbritin Paediatric Suspension: Bottles of 25 ml.

Penbritin Paediatric Tablets: Canisters of 100.

Further information Nil.

PYOPEN* INJECTION PYOPEN* INFUSION

Presentation *Pyopen 1 g Vial:* Vials containing 1 g carbenicillin as Carbenicillin Sodium BP.

Pyopen 5 g Vial: Vials containing 5 g carbenicillin as Carbenicillin Sodium BP.

Pyopen Infusion: Infusion bottles containing 5 g carbenicillin as Carbenicillin Sodium BP.

Uses Pyopen is indicated primarily for the treatment of infections caused by sensitive *Pseudomonas* and *Proteus* species.

At recommended dosages, Pyopen is also effective against a wide range of other Gram-negative and Gram-positive bacteria, including: *Escherichia coli*, *Haemophilus influenzae*, *Bacteroides fragilis* and other anaerobes, *Clostridium* spp., *Staphylococcus aureus* (penicillin sensitive), *Streptococcus* spp.

Typical indications include: General Systemic Infections, Respiratory Tract Infections, Septicaemia, Urinary Tract Infections, Post-surgical Infections, Intra-abdominal sepsis, Endocarditis, Meningitis, Infected Burns, Infected Wounds.

In life-threatening infections, consideration should be given to the synergistic effects of Pyopen and a parenteral aminoglycoside; they should be given separately, at recommended dosages.

Dosage and administration *Dosage:* See table below.

Preparation 1 gram vial: *Intramuscular:* Add 2 ml Water for Injections BP to the contents of the vial and shake vigorously.

Intravenous: Add 5 ml Water for Injections BP to the contents of the vial and shake vigorously. Dilute to 20 ml.

5 gram vial (50 ml): *Intravenous injection:* Add at least 20 ml Water for Injections BP to the contents of the 5 g vial and shake vigorously.

Intravenous infusion: Add 20 ml Water for Injections BP to the contents of the 5 g vial, shake vigorously and add to a suitable volume of infusion fluid (approximately 100–150 ml).

5 g vials are not suitable for multidose use.

Infusion pack: See detailed instructions contained in Package Enclosure Leaflet.

Administration: *Intramuscular:* Pyopen should be given every six hours.

Intravenous: Pyopen should be given every four to six hours by slow injection (three to four minutes) or by rapid infusion over 30–40 minutes (i.e. at a rate of approximately 50 drips per minute). Infusion over longer periods may result in sub-therapeutic serum concentrations.

Higher and more prolonged serum concentrations may be achieved with concurrent oral administration of probenecid (1 g three times a day in adults); however, caution should be exercised in the administration of probenecid to patients with impaired renal function.

† *Intrathecal:* An intrathecal preparation and further information may be obtained from the Company's Medical Department.

Pyopen may be administered by other routes in conjunction with systemic therapy.

Intra-articular: Add 2–4 ml Water for Injections BP or

† Intrathecal therapy: see 'Administration'

Dosage of Pyopen

<i>Infection</i>	<i>Organism</i>	
	<i>Pseudomonas</i>	<i>Proteus spp.</i>
Adult		
Respiratory tract infections Chronic urinary tract infections Infected wounds and burns	5 g i.v. four to six-hourly	2 g i.m. six-hourly
Systemic infections Septicaemia, endocarditis, meningitis†		
Acute uncomplicated urinary tract infections		
Paediatric (daily dosage per kg body weight: to be administered in divided doses 4–8 hourly)		
Respiratory tract infections Chronic urinary tract infections Infected wounds and burns	250–400 mg i.v.	100 mg i.m.
Systemic infections Septicaemia, endocarditis, meningitis†		
Acute uncomplicated urinary tract infections		

† Intrathecal therapy: see 'Administration'.

0.5% lignocaine solution to the contents of a 1 g vial. 500 mg to 1 g is a suitable dosage.

Intrapleural: Add 5 ml Water for Injections BP to the contents of a 1 g vial. Dilute to 10 ml. This dosage is normally given once daily.

Nebuliser Solution: Dissolve 250–500 mg Pyopen powder in 3–5 ml of water and administer four times daily by a suitable nebuliser.

Subconjunctival: A 25% solution (125 mg in Lignocaine and Adrenaline Injection BP) is recommended.

Local irrigation: A 0.2% solution of Pyopen should be used.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Side-effects: Side-effects are uncommon and typical of other injectable penicillins. If pain at the intramuscular injection site is troublesome, the vial contents may be dissolved in 0.5% lignocaine hydrochloride solution. In rare cases, spontaneous skin and mucous membrane haemorrhages due to interference with normal clotting mechanisms have been reported.

Precautions: Except in cases of renal impairment, recommended dosages should never be reduced. Administration at less than full dosage may permit the multiplication of resistant strains, especially of *Pseudomonas*. Where renal function is impaired, Pyopen dosage may be reduced. However, monitoring is advisable in these cases to ensure that adequate serum antibiotic concentrations are achieved. In treating patients on sodium restriction it should be noted that each 1 g vial of Pyopen contains 5.4 mmol sodium (approx. 124 mg), and each 5 g vial contains 27.1 mmol sodium.

When Pyopen is used with an aminoglycoside the usual dosage should be adopted; concurrent therapy is not an opportunity to secure dosage reduction unless indicated for other reasons – for instance renal failure.

If Pyopen is prescribed with a parenteral aminoglycoside, the compounds should be administered separately.

Pharmaceutical precautions *Stability and storage:* Pyopen is unstable to heat and is very hygroscopic. The

vials of dry powder should be stored in a refrigerator at 5°C.

Solutions for IM and direct IV injection should normally be administered within 30 minutes of preparation. However, aqueous solutions of Pyopen retain their activity for up to 24 hours at room temperature (25°C) and for up to 72 hours in the refrigerator (5°C). If storage for this increased period is necessary, reconstitution should be carried out under appropriate aseptic conditions. Details of the stability of Pyopen in various fluids are given in the Package Enclosure Leaflet.

Compatibility: Pyopen is compatible with intravenous solutions in general use except: proteinaceous fluids (e.g. protein hydrolysates), blood and plasma.

Legal category POM.

Package quantities

Pyopen 1 g Vials: Cartons of 10.

Pyopen 5 g Vials: Cartons of 6 (50 ml vials).

Pyopen Infusion: 5 g infusion bottle, with diluent and transfer needle, in packs of 6.

Further information Pyopen continues to be effective in patients with lowered host defences.

TALPEN*

Presentation *Talpen Tablets:* Red film coated tablets, engraved Talpen on one side. Each tablet contains 250 mg of the ampicillin ester, talampicillin hydrochloride.

Talpen Syrup: Bottles containing powder for the preparation of 100 ml suspension. When reconstituted each 5 ml contains talampicillin napsylate (167 mg) equivalent to 125 mg talampicillin hydrochloride.

Talpen Syrup Forte: Bottles containing powder for the preparation of 100 ml suspension. When reconstituted each 5 ml contains talampicillin napsylate (334 mg) equivalent to 250 mg talampicillin hydrochloride.

Uses Following oral administration, Talpen is particularly well absorbed and rapidly hydrolysed to give high blood levels of ampicillin. Talpen is indicated for the oral treatment of a wide range of bacterial infections caused by commonly occurring pathogens, for example:

Gram-positive: Penicillin sensitive *Staph. aureus*, *Strep. pyogenes*, *Strep. faecalis*, *Strep. viridans*, *Strep. pneumoniae*, *Clostridium species*, *Bacillus anthracis*, *Corynebacterium diphtheriae*.

Gram-negative: *Neisseria gonorrhoeae*, *Neisseria meningitidis*, *Escherichia coli*, *Haemophilus influenzae*, *Bordetella pertussis*, *Salmonella typhi*, *Salmonella paratyphi*, *Salmonellae* (other), *Shigella species*, *Brucella species*, *Proteus mirabilis*.

Typical indications include: Acute and chronic bronchitis; Pneumonia; Ear, nose and throat infections; Gynaecological infections; Urinary tract infections; Skin and soft tissue infections; Gonorrhoea.

Dosage and administration *Usual adult oral dosage:* †One Talpen tablet or 5 ml Talpen Syrup Forte, three times a day.

Gonorrhoea: 1.5–2 g talampicillin hydrochloride as a single dose, is recommended.

Usual children's oral dosage: (2–10 years) †5 ml Talpen Syrup, three times a day. (Under two years) the equivalent of 3–7 mg talampicillin hydrochloride per kilogram body weight, three times a day. (Talpen Syrup may be diluted with Syrup BP.)

Total ampicillin availability following oral administration of Talpen is unaffected by food.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Precaution: Talpen is not recommended for patients with severe renal or hepatic impairment.

Side-effects: As with other penicillins. These are rare and usually of a mild and transitory nature. An erythematous rash may occasionally occur. The incidence of this rash is particularly high in patients with infectious mononucleosis. Controlled clinical trials have shown that the incidence of diarrhoea as a side-effect is significantly lower following the administration of Talpen than following oral ampicillin.

Pharmaceutical precautions Talpen should be stored in tightly closed containers and kept in a cool dry place. Talpen Syrup and Syrup Forte should be used within seven days of dispensing, and should be kept in a cool place, preferably a refrigerator.

Legal category POM.

Package quantities *Talpen Tablets:* Bottles of 100 and 500.

Talpen Syrup: Bottles of 100 ml.

Talpen Syrup Forte: Bottles of 100 ml.

Further information Following oral administration of 250 mg Talpen, ampicillin peak serum concentrations are twice those obtained from 250 mg ampicillin capsules and are usually achieved in half the time. This excellent absorption is further reflected in urinary recovery studies.

Each 250 mg of talampicillin hydrochloride is chemically equivalent to 169 mg of ampicillin.

Talpen Syrup Forte 0038/0245

TICAR* ▼

Presentation *Ticar 1 g vial:* Vials containing 1 g ticarcillin as the disodium salt.

Ticar 3 g vial: Vials containing 3 g ticarcillin as the disodium salt.

Ticar 5 g vial: Vials containing 5 g ticarcillin as the disodium salt.

Ticar infusion: Infusion bottles containing 5 g ticarcillin as the disodium salt.

Uses Ticar is an injectable broad-spectrum penicillin indicated for the treatment of a wide range of bacterial infections. Sensitive organisms include:

Streptococcus species
Staphylococcus aureus (penicillin sensitive)
Clostridium species
Bacteroides species and other anaerobes
Pseudomonas species
Proteus species
E. coli
Haemophilus influenzae

Typical indications include:

General Systemic Infections
Respiratory Tract Infections
Septicaemia
Urinary Tract Infections
Peritonitis, intra-abdominal sepsis
Endocarditis
Infected burns
Infected wounds
Post-surgical infections

Ticar acts synergistically with aminoglycosides against *Pseudomonas* and other organisms. When Ticar is prescribed concurrently with an aminoglycoside the two products should be administered separately, at recommended dosages.

Dosage and administration *Dosage: Adults:* The normal recommended daily dosage is 15–20 g administered in divided doses, usually at 4–8 hourly intervals.

For the treatment of acute uncomplicated urinary tract infections the normal recommended daily dosage is 3–4 g in divided doses, usually at 4–8 hourly intervals.

Children: The normal recommended dosage for children is 200–300 mg/kg/day in divided doses, usually at 4–8 hourly intervals.

For acute uncomplicated urinary tract infections the recommended dosage is 50–100 mg/kg/day in divided doses, usually at 4–8 hourly intervals.

Abnormal Renal Function: If renal function is impaired as indicated by urea or creatinine levels monitoring of antibiotic serum levels is advised and a reduction in dosage may need to be considered. In renal failure an appropriate adult dose would be 2 g every 8–12 hours. In such cases the serum half life may be as long as 13 hours compared with 70 minutes in normal subjects. (Corresponding reductions in dosage should be considered for children.)

† Dosage may be doubled in severe infections.

Haemodialysis removes Ticar from the blood stream therefore a supplementary 2 g dose is recommended midway through the dialysis period.

Peritoneal dialysis removes Ticar at a slower rate than haemodialysis therefore a dosage of 2 g 8 hourly is recommended.

Preparation: 1 gram vial: Intramuscular – Add 2 ml Water for Injections BP and shake vigorously.

Intravenous – Add 5 ml Water for Injections BP and shake vigorously. Dilute to 20 ml.

3 gram vial: Intravenous injection: Add 20 ml Water for Injections BP and shake vigorously.

Intravenous infusion: Add 20 ml Water for Injections BP shake vigorously and add to a suitable volume of infusion fluid (approximately 100 ml).

5 gram vial: Intravenous injection: Add 20 ml Water for Injections BP and shake vigorously.

Intravenous infusion: Add 20 ml Water for Injections BP shake vigorously and add to a suitable volume of infusion fluid (approximately 100–150 ml).

Water for Injections BP is the preferred diluent for intravenous infusion of Ticar. Alternatively, the antibiotic may be infused in 5% dextrose solution. (The use of 0.9% sodium chloride solution as diluent will add to the sodium load of ticarcillin and is, therefore, not usually recommended). The use of these appropriate diluents, when Ticar is given intravenously, will reduce the possibility of phlebitis.

Infusion pack: See detailed instructions on Package Enclosure Leaflet.

Reconstituted solutions of Ticar are normally a pale straw colour.

Heat is generated when Ticar dissolves. Ticar vials may therefore become warm during preparation of solutions for injection.

Ticar vials are not suitable for multi-dose use.

Administration: When administered intravenously Ticar should be given by slow injection (three to four minutes) or by infusion over e.g. 30–40 minutes (i.e. at a rate of approximately 50 drops per minute). Infusion over long periods may result in subtherapeutic concentrations.

Higher and more prolonged serum concentrations may be achieved with concurrent oral administration of probenecid (1 g three times a day in adults); however, caution should be exercised in the administration of probenecid to patients with impaired renal function.

Other routes of administration: Insufficient clinical information is available to assess fully the value of Ticar by the following routes of administration. In life-threatening infections, however, the following dosage guidelines may be helpful. In all cases systemic Ticar therapy, at full dosage, should also be administered.

Nebuliser solution: Dissolve 500 mg Ticar powder in 3–5 ml water (or smaller volume if required). Administer this dosage three to four times daily by a suitable nebuliser.

Intra-articular: Add 2–4 ml Water for Injections BP or 0.5% lignocaine solution to the contents of a 1 g vial. 500 mg to 1 g is a suitable dosage.

Intrapleural: Add 5 ml Water for Injections BP to the contents of a 1 g vial. Dilute to 10–20 ml. This dosage is normally given once daily.

Local irrigation: A 0.2% solution of Ticar may be used.

Intrathecal: Further information may be obtained from the Company's Medical Department.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Side-effects: Side-effects are uncommon and typical of other injectable penicillins. If pain at the intramuscular injection site is troublesome the vial contents may be dissolved in 0.5% lignocaine hydrochloride solution. In rare cases spontaneous skin and mucous membrane haemorrhages due to interference with normal clotting mechanisms have been reported.

Precautions: Use of Ticar at less than recommended dosages may permit multiplication of resistant strains of bacteria especially of *Pseudomonas*. For patients with abnormal renal function see 'Dosage and Administration'. In treating patients on sodium restriction it should be noted that each 1 g vial of Ticar contains 5.3 mmol of sodium (approx.) each 3 g vial contains 16.0 mmol of sodium (approx.) and each 5 g vial contains 26.7 mmol of sodium (approx.)

Pharmaceutical precautions *Stability and storage:* Vials of Ticar powder should be stored at room temperature (25°C or below).

Solutions for IM and direct IV injection should normally be administered within 30 minutes of preparation. However, aqueous solutions of Ticar retain their activity for up to 24 hours at room temperature (25°C) and for up to 72 hours in the refrigerator (5°C). If storage for this increased period is necessary, reconstitution should be carried out under appropriate aseptic conditions. Details of the stability of Ticar in various fluids are given in the Package Enclosure Leaflet.

Compatibility: Ticar is compatible with intravenous solutions in general use except:

Proteinaceous fluids (e.g. protein hydrolysates)
Blood and plasma
Intravenous lipids

If Ticar is prescribed concurrently with an aminoglycoside the antibiotics should not be mixed in the syringe or intravenous fluid container because loss of activity of the aminoglycoside can occur under these conditions.

Legal category POM.

Package quantities Ticar 1 g vials: Cartons of 10.

Ticar 3 g vials: Cartons of 6.

Ticar 5 g vials: Cartons of 4.

Ticar infusion: 5 g infusion bottle with diluent and transfer needle, in packs of 4.

Further information Ticar has proved to be particularly valuable in the treatment of patients with lowered host defences.

Synergy has been observed between Ticar and aminoglycosides, such as gentamicin, tobramycin and amikacin, against *Pseudomonas* and other organisms. When Ticar is used with an aminoglycoside the usual recommended dosages of both products should be used. Concurrent therapy is not an opportunity to secure dosage reduction unless indicated for other reasons – for example renal failure. (See manufacturers' literature for details of aminoglycoside prescribing information.)

As with other penicillins, Ticar is eliminated by glomerular filtration and tubular secretion. It is not highly bound to serum protein (approximately 45%) and is excreted unchanged in high concentrations in the urine.

Ticar can be detected in tissues and interstitial fluid following parenteral administration. Penetration into the cerebrospinal fluid, bile and pleural fluid has been demonstrated.

UTICILLIN* TABLETS

Presentation Oval, white tablets, engraved 'Uticillin'. Each Uticillin Tablet contains 500 mg carfecillin sodium.

Uses Uticillin is indicated for the treatment of acute and chronic infections of the upper and lower urinary tract when these are caused by sensitive organisms, including *Escherichia coli*, *Proteus* spp. and *Strep. faecalis*. Uticillin is of particular value in the treatment of *Pseudomonas* urinary tract infections.

Typical indications include: Cystitis. Pyelonephritis. Asymptomatic bacteriuria.

Dosage and administration *Adults*: Simple urinary tract infections – 1 tablet (500 mg) three times a day.

Complicated and recurrent urinary tract infections – 2 tablets (1 g) three times a day.

Children: 2–10 years: $\frac{1}{2}$ adult dose.

Children's dosage should be in the range 30–60 mg/kg daily in 3 divided doses.

Contra-indications, warnings, etc

Contra-indication: Penicillin hypersensitivity.

Side-effects: As with other penicillins.

Precaution: In mild and moderate degrees of renal impairment, the normal dosage recommendations should be followed. In patients with severe renal failure (creatinine clearance of 10 ml/min or less) carfecillin is not recommended; in such patients the levels of carbenicillin in the urine may be insufficient for therapeutic efficacy.

Pharmaceutical precautions Uticillin should be stored in a cool, dry place.

Legal category POM.

Package quantities Bottles of 30.

Further information *Pharmacology*: Following oral administration, Uticillin is rapidly absorbed in the body and hydrolysed to carbenicillin, producing high concentrations in the urine.

Product licence number 0038/0155.

ALAVAC-P*

Presentation Alavac-P vaccine contains alum-precipitated extracts from aqueous pyridine solutions or twelve varieties of common grass pollens: (Bent, Brome, Cocksfoot, Crested Dogtail, False Oat, Fescue, Meadow Foxtail, Meadow Grass, Rye Grass, Timothy, Vernal and Yorkshire Fog).

The vaccine consists of a set of three multidose vials in graded concentrations as follows:

Vial Number	Concentration
1. (Green Label)	250 Noon units per ml.
2. (Buff Label)	2,500 Noon units per ml.
3. (Red Label)	25,000 Noon units per ml.

The aluminium hydroxide content is not more than 3 mg/ml and the preparation is preserved with Phenol BP 0.5% w/v.

Uses Indicated for the treatment of classical hayfever and pollen asthma, to give long-term protection whenever grass pollens are considered to be the sole or predominant cause.

Alavac-P is formulated from the pollens of twelve common grasses which are responsible for the majority of classical hayfever and pollen asthma cases and provides a convenient and effective preventive treatment.

Dosage and administration Please note that the section on 'Contra-Indications, Warnings, Etc.' must be studied before Alavac-P is administered.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

The administration procedures shown in the leaflet included with each course of Alavac-P should be carefully followed.

Alavac-P may be given to adults and children aged 5 years and over in accordance with the provisions given below.

Injections should be given at intervals of 7-14 days.

The vial should be shaken thoroughly immediately before withdrawing a dose.

Sterile syringes should always be used for the withdrawal of doses. Since each vial is used more than once, aseptic precautions must be sufficient to avoid the risk of microbial contamination.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Treatment should be given pre-seasonally. The course should normally be started by mid-March (in the UK) to ensure completion before the onset of the grass pollen season. For continued clinical improvement it is recommended that a course should be given in each of three successive years.

Dosage schemes:

Adults

The dosage scheme should be selected according to the patient's previous history of asthma and severity of allergic symptoms as outlined below. When in doubt, treatment should be commenced at the lowest dosage.

Patient Classification

Very sensitive	Moderately sensitive	Mildly sensitive
Severe symptoms of allergy (e.g. eczema) or any history of asthma	Moderate symptoms of allergy with no history of asthma	Mild symptoms of allergy with no history of asthma

Children

Children aged 5-14 years: treat according to the child's dosage scheme shown below. However, in the presence of a history of asthma or severe symptoms, consultant advice should be sought.

Children under five: consultant advice should be sought.

Recommended dosage schemes

Not to be used during the grass pollen season.

Commence with the No. 1 (Green label) vial then proceed to the No. 2 (Buff label) vial and the No. 3 (Red label) vial as indicated in the scheme below.

If a reaction occurs during treatment, dosage should be reduced: see 'Adjustment of Dosage'.

Adults:

Vial number	Very sensitive adult patients	Moderately sensitive adult patients	Mildly sensitive adult patients
	dosage (ml)	dosage (ml)	dosage (ml)
1. Green label	0.1 0.2 0.4 0.8	0.2 0.5	0.5
2. Buff label	0.15 0.3 0.6	0.1 0.2 0.4 0.8	0.1 0.3 0.7
3. Red label	0.1 0.2	0.15 0.25 0.4	0.15 0.3 0.5 1.0

Children:

Vial Number	Dosage for children aged 5–14 years (ml)	Children under five
1. Green label	0.1 0.2 0.4 0.8	Children under five: consultant advice should be sought
2. Buff label	0.15 0.3 0.6	
3. Red label	0.1 0.2	

Extended treatment: when time is available before the onset of the pollen season and there is sufficient vaccine, it may be beneficial to repeat the top treatment dose at fortnightly intervals, the final dose being given two weeks before the pollen season is expected to start.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from febrile conditions or an acute attack of asthma should not be given an injection until 24 hours after the condition has subsided.

It is advisable to avoid use during pregnancy, especially in the first trimester.

Precautions: Children under five: consultant advice should be sought.

Patients should be warned not to eat a heavy meal immediately before an injection is due to be given.

In very sensitive patients, it is advantageous to give an antihistamine tablet about one hour before each injection.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

All patients should be instructed to remain under observation in the surgery for at least 20 minutes after each injection and advised to contact the doctor immediately in the unlikely event of a delayed reaction.

The patient should not take any strenuous physical exercise for several hours following the injection.

Note: A patient must not be transferred from Alavac-P to an aqueous vaccine unless a complete course of the aqueous vaccine is to be given, commencing with the lowest strength (No. 1) vial.

Reactions: (see also 'Adjustment of Dosage'):

Local reactions, such as slight swelling or irritation, can sometimes occur and may require symptomatic treatment if they persist.

Mild systemic reactions such as rhinitis or urticaria may be treated with antihistamines orally, or by injection if necessary. In mild bronchospasm, a sympathomimetic bronchodilator such as salbutamol and possibly an anti-inflammatory steroid should be given. If required, 0.5 ml Adrenaline Injection BP (1 in 1,000) may be given subcutaneously.

Severe systemic reactions may occasionally arise in the form of typical allergic symptoms; anaphylaxis is rare.

Treatment of anaphylaxis:

Anaphylactic shock: characterised by bronchospasm,

laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.

2. 0.5 ml† Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml† over 15 minutes if necessary. In extreme cases, 0.5 ml† Adrenaline (1 in 10,000) can be given by slow intravenous injection.

3. If bronchospasm persists, 10–20 ml† of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml† per minute.

4. In addition, 200–400 mg† of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.

5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

Adjustment of Dosage (in the event of the occurrence of a reaction):

Reaction to the first injection:

Moderately sensitive or mildly sensitive adult dosage scheme: The patient should be transferred to the very sensitive adult dosage scheme.

Very sensitive adult dosage scheme and children: return the complete course to Bencard. An appropriate course of Alavac-S containing grass pollens together with a Special Dilution Vial (No. 0 – Black label, 1/10th dilution of the No. 1 vial) will be supplied free of charge. Treatment should recommence from the Special Dilution Vial according to the dosage scheme issued with it; the normal dosage scheme should then be continued, but no attempt should be made to exceed the maximum tolerated dose.

Reaction to subsequent injections:

Local

Mild reaction: Reduce the dose by one step.

Severe reaction: Reduce the dose by two steps.

Systemic

Mild reaction: Reduce the dose by two steps.

Severe reaction: Treatment should be discontinued.

Except in cases where a severe systemic reaction has occurred, the course may be continued with caution up to the top dose quoted, or to the highest dose tolerated without significant reaction.

Pharmaceutical precautions Alavac-P must be stored in a refrigerator (2–8°C). It must not be frozen. Vaccine left over from an Alavac-P course must not be used the following year.

Legal category POM.

Package quantities Each course of treatment consists of a set of three multidose vials of vaccine in graded concentrations. Ready assembled disposable syringes with attached needles and an instruction leaflet are included with each set.

Further information Alavac-P is formulated from the pollens of twelve common grasses responsible for classical hayfever and pollen asthma and offers a fundamental alternative to symptomatic treatment. Alavac-P may be prescribed from case history and clinical symptoms alone, providing these reveal marked seasonality corresponding with the grass pollen season. Risk of

† All dosages should be reduced as required for children.

reaction is reduced because of the slow release of active material into the system.

Alavac-P may be prescribed on NHS form FP10 and is available for immediate supply from stock.

The Bencard Medical Department will be pleased to advise on any aspect of treatment.

Product licence number 0038/5085.

ALAVAC-S*

Presentation Each course of Alavac-S is a desensitising vaccine, specially prepared for an individual patient, from extracts of specific allergens, in accordance with the information obtained from the patient during case history investigations and subsequent skin tests. The vaccine comprises alum-adsorbed extracts of specific allergens precipitated from aqueous pyridine solutions. Each course is presented as three multidosed vials of allergen concentrate in graded concentrations. The No. 1 and No. 2 vials are 1/100th and 1/10th dilutions respectively of the No. 3 vial.

Special Dilution Vials (No. 0, Black label, 1/10th dilution of the No. 1 vial) are available on request to initiate treatment of highly sensitive patients.

The No. 3 vial is also available in a larger size for physicians practising maintenance therapy with courses which do not contain pollen allergens (see Dosage and Administration).

For the best clinical results with Alavac-S, no more than 4 allergens should normally be included (with a maximum of 6) in any one course.

If the patient is sensitive to more than 6 allergens, those which can be avoided without undue inconvenience, or are of little clinical significance, should be omitted and the patient given advice on avoidance; otherwise two separate vaccines will be prepared.

The aluminium hydroxide content is not more than 3 mg/ml and the preparation is preserved with Phenol BP 0.5% w/v.

The adsorbed allergen extracts available for inclusion in Alavac-S are:

Dusts: Hay dust, House dust, Straw dust, Mixed threshings (barley, maize, oats and wheat).

Epithelials: Mixed feathers, Cat fur, Rabbit fur, Cow hair, Dog hair, Horse hair, Human hair, Sheep wool.

Fabrics: Cotton flock, Kapok.

House Dust Mite: *Dermatophagoides pteronyssinus*.

Fungi: *Alternaria alternata*, *Aspergillus fumigatus*, *Aspergillus niger*, *Candida albicans*, *Cladosporium herbarum*, *Fusarium spp.*, *Merulius lacrymans*, *Neurospora sitophila*, *Penicillium notatum*, *Rhizopus nigricans*, *Sporobolomyces roseus*, *Trichophyton (T. mentagrophytes and T. rubrum)*.

Pollens: Available individually:

Elder (*Sambucus nigra*), Hazel (*Corylus spp.*), Maize (*Zea mays*), Nettle (*Urtica dioica*), Plantain (*Plantago lanceolata*), Poplar (*Populus spp.*), Rye, Cultivated (*Secale cereale*), Silver Birch (*Betula spp.*).

Available as standard groups.

Group B2-Grass pollens containing:

Bent, Brome, Cocksfoot, Crested Dogtail, False Oat, Meadow Fescue, Meadow Foxtail, Meadow Grass, Rye Grass, Timothy, Vernal, Yorkshire Fog.

Group B3-Tree pollens containing:

Alder, Ash, Beech, Birch, Elm, Hazel, Oak, Plane, Poplar, Willow.

Group B5-Weed and Shrub pollens containing:

Heather, Nettle, Plantain, Fat Hen, Mugwort, Orache.

The allergens used in the preparation of Alavac-S correspond with those available as Bencard Skin Testing Solutions. Alavac vaccines themselves are unsuitable for skin testing.

Uses To provide fundamental treatment for a wide variety of common allergic conditions such as asthma, perennial rhinitis, hay fever and some skin conditions.

Dosage and administration Please note that the section on 'Contra-Indications, Warnings, Etc.' must be studied before Alavac-S is administered.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

The administration procedures shown in the leaflet included with each course of Alavac-S should be carefully followed.

Alavac-S may be given to adults and children aged 5 years and over in accordance with the guidelines given below.

Children under five: consultant advice should be sought.

Injections should be given at intervals of 7–14 days unless otherwise stated.

The vial should be shaken thoroughly immediately before withdrawing a dose.

Sterile syringes should always be used for the withdrawal of doses. Since each vial is used more than once, aseptic precautions must be sufficient to avoid the risk of microbial contamination.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adults

The dosage scheme should be selected according to the patient's previous history of asthma and severity of allergic symptoms as outlined below. When in doubt, treatment should be commenced at the lowest dosage.

Patient Classification

Very sensitive	Moderately sensitive	Mildly sensitive
Severe symptoms of allergy (e.g. eczema) or any history of asthma	Moderate symptoms of allergy with no history of asthma	Mild symptoms of allergy with no history of asthma

Children

Children aged 5–14 years: treat according to the children's dosage scheme shown below. However, in the presence of a history of asthma or severe symptoms, consultant advice should be sought.

Children under five: consultant advice should be sought.

Alavac-S: Dosage recommendations for vaccines which contain pollen allergens:

Treatment should be given pre-seasonally. The course should be timed to end before the usual date of onset of the patient's seasonal symptoms (e.g. in the UK, by mid-May for grass pollen sensitivity and by the end of March for tree pollen sensitivity). For continued clinical improvement it is recommended that a course should be given in each of three successive years.

Recommended dosage schemes for vaccines which contain pollen allergens

Not to be used during the pollen season.

Commence with the No. 1 (Green label) vial then proceed to the No. 2 (Buff label) vial and the No. 3 (Red label) vial as indicated in the schemes below.

If a reaction occurs during treatment, dosage should be reduced: see 'Adjustment of Dosage'.

Adults:

Vial Number	Very sensitive adult patients	Moderately sensitive adult patients	Mildly sensitive adult patients
	dosage (ml)	dosage (ml)	dosage (ml)
1. Green label	0.1 0.2 0.4 0.8	0.2 0.5	0.5
2. Buff label	0.15 0.3 0.6	0.1 0.2 0.4 0.8	0.1 0.3 0.7
3. Red label	0.1 0.2	0.15 0.25 0.4	0.15 0.3 0.5 1.0

Children:

Vial Number	Dosage for children aged 5–14 years (ml)	Children under five
1. Green label	0.1 0.2 0.4 0.8	Children under five: consultant advice should be sought.
2. Buff label	0.15 0.3 0.6	
3. Red label	0.1 0.2	

Surplus vaccine must not be used the following season.

Extended treatment: when time is available before the onset of the pollen season and there is sufficient vaccine, it may be beneficial to repeat the top treatment dose at fortnightly intervals, the final dose being given two weeks before the pollen season is expected to start.

Alavac-S: Recommended dosage schemes for vaccines which do not contain pollen allergens (Initial course)
Courses may be given at any time of year.

Commence with the No. 1 (Green label) vial then proceed to the No. 2 (Buff label) vial and the No. 3 (Red label) vial as indicated in the schemes below.

If a reaction occurs during treatment, dosage should be reduced: see 'Adjustment of Dosage'.

Adults

Vial Number	Very sensitive adult patients	Moderately sensitive adult patients	Mildly sensitive adult patients
	dosage (ml)	dosage (ml)	dosage (ml)
1. Green label	0.25 0.5 1.0	0.5 1.0	
2. Buff label	0.2 0.4 0.8	0.2 0.4 0.8	0.1 0.2 0.4 0.8
3. Red label	0.15 0.25	0.15 0.3 0.6	0.15 0.3 0.6

Maintenance treatment following the initial course is recommended.

Children

Vial Number	Dosage for children aged 5–14 years (ml)	Children under five
1. Green label	0.25 0.5 1.0	Children under five: consultant advice should be sought.
2. Buff label	0.2 0.4 0.8	
3. Red label	0.15 0.25	

Maintenance treatment following the initial course is recommended.

Maintenance therapy: (for use only with vaccines which do not contain pollens)

Maintenance therapy, which consists of a series of boosting injections, is recommended particularly for patients with perennial symptoms provided that the initial treatment course has been well tolerated.

Maintenance therapy should commence between 1 and 2 weeks after completion of the initial course, and should follow the dosage scheme below. Treatment may be continued at the discretion of the physician, with review at appropriate intervals.

N.B. Maintenance therapy is not suitable for use with pollen-containing vaccines.

Recommended maintenance dosage schemes for vaccines which do NOT contain pollen allergens.

Injections should be given from vial No. 3.

If a reaction occurs during treatment, dosage should be reduced: see 'Adjustment of Dosage'.

N.B. Care should be taken when administering the first injection from a new No. 3 vial, as in a very few cases a local or general reaction may occur.

If a period of five to eight weeks has elapsed since the last injection, from the previous No. 3 vial, the first two doses from the new No. 3 vial should be modified according to the following recommendations:

Adults: Maintenance Dosage Scheme (Using No. 3 vial supplied with Initial Course).

Injection Number	Interval since previous injection	Dosage (ml) from No. 3 Vial (use maximum tolerated dose if lower)		Duration
		very sensitive adults	moderately or mildly sensitive adults	
First	1–2 weeks after completion of Initial Course	0.25	0.6	Maintenance therapy may be continued at the discretion of the physician, with review at appropriate intervals.
2nd	1–2 weeks	0.25	0.6	
3rd	2 weeks	0.25	0.6	
4th	2 weeks	0.25	0.6	
5th and subsequent	4 weeks	0.25	0.6	

Children: (aged 5–14 years) Maintenance Dosage Scheme (Using No. 3 vial supplied with Initial Course).*

Injection Number	Interval since previous injection	Dosage (ml) from No. 3 vial (use maximum tolerated dose if lower)	Duration
First	1–2 weeks after completion of Initial Course	0.25	Maintenance therapy may be continued at the discretion of the physician, with review at appropriate intervals.
2nd	1–2 weeks	0.25	
3rd	2 weeks	0.25	
4th	2 weeks	0.25	
5th and subsequent	4 weeks	0.25	

* Children under five: consultant advice should be sought.

- for very sensitive adults and for children the first dose should be 0.05 ml and the second dose 0.15 ml
 - for moderately or mildly sensitive adults the first dose should be 0.15 ml and the second dose 0.3 ml
- given at an interval of 7–14 days.

Maintenance treatment should then be continued as shown in the above tables.

If more than eight weeks have elapsed since the previous injection, it is advisable not to attempt maintenance therapy but to re-start with a complete initial course, commencing with the lowest strength (No. 1 Green label) vial.

This regimen is unsuitable for use with pollen-containing vaccines.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from febrile conditions or an acute attack of asthma should not be given an injection until 24 hours after the condition has subsided.

It is advisable to avoid use during pregnancy, especially in the first trimester.

Precautions: Children under five: consultant advice should be sought.

Patients should be warned not to eat a heavy meal immediately before an injection is due to be given.

In very sensitive patients it is advantageous to give an antihistamine tablet about one hour before each injection.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

All patients should be instructed to remain under observation in the surgery for at least 20 minutes after each injection and advised to contact the doctor immediately in the unlikely event of a delayed reaction. The patient should not take any strenuous physical exercise for several hours following the injection.

Note: A patient must not be transferred from Alavac-S to an aqueous vaccine unless a complete course of the aqueous vaccine is to be given, commencing with the lowest strength (No. 1 Green label) vial.

Reactions (see also 'Adjustment of Dosage'):

Local reactions, such as slight swelling or irritation, can sometimes occur and may require symptomatic treatment if they persist.

Mild systemic reactions such as rhinitis or urticaria may be treated with antihistamines orally, or by injection if necessary. In mild bronchospasm, a sympathomimetic bronchodilator such as salbutamol and possibly an anti-inflammatory steroid should be given. If required, 0.5 ml

Adrenaline Injection BP (Adrenaline 1 in 1,000) may be given subcutaneously.

Severe systemic reactions may occasionally arise in the form of typical allergic symptoms; anaphylaxis is rare.

Treatment of anaphylaxis:

Anaphylactic shock: characterised by bronchospasm, laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.
2. 0.5 ml† Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml† over 15 minutes if necessary. In extreme cases, 0.5 ml† Adrenaline (1 in 10,000) can be given by slow intravenous injection.
3. If bronchospasm persists, 10–20 ml† of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml† per minute.
4. In addition, 200–400 mg† of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.
5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

Adjustment of Dosage (in the event of the occurrence of a reaction):

Reaction to the first injection

Moderately sensitive or mildly sensitive adult dosage scheme: The patient should be transferred to the very sensitive adult dosage scheme.

Very sensitive adult dosage scheme and children: return the complete course to Bencard. A Special Dilution Vial (No. 0 – Black label, 1/10th dilution of the No. 1 vial) will be prepared free of charge and returned with a new complete course.

Treatment should recommence from the dilute vial according to the dosage scheme issued with it; the normal dosage scheme should then be continued, but no attempt should be made to exceed the maximum tolerated dose.

Reaction to subsequent injections:

Local

Mild reaction: Reduce the dose by one step.

Severe reaction: Reduce the dose by two steps.

Systemic

Mild reaction: Reduce the dose by two steps.

Severe reaction: Treatment should be discontinued.

Except in cases where a severe systemic reaction has occurred, the course may be continued with caution up to the top dose quoted, or to the highest dose tolerated without significant reaction.

Pharmaceutical precautions Alavac-S must be stored in a refrigerator (2–8°C). It must not be frozen.

Surplus vaccine from courses of Alavac-S containing pollen allergens must not be used the following year.

Vaccine left over from the No. 3 vial of courses which do not contain pollen allergens may be used for maintenance therapy (see Maintenance therapy for vaccines which do not contain pollen allergens).

Legal category POM.

Package quantities Each course of treatment consists of a set of three multidose vials of vaccine in graded

concentrations. Ready-assembled disposable syringes with attached needles and an instruction leaflet are included with each set. The No. 3 vial is also available in a larger size for maintenance therapy with Alavac-S vaccines which do not contain pollen allergens (see Dosage and Administration).

Normal delivery time for a complete course or a single vial is about two weeks to allow for individual formulation and sterility testing.

Further information Ordering procedure: FP10 forms (or other prescriptions) should be taken to a chemist who will arrange the supply of the vaccine. The prescription should be accompanied by the following information:

When available, a Skin Test Reaction Chart or a list of the allergens to be included in the vaccine with a note of the patient's sensitivity to each one, or, the reference number of a previous course.

Patient's name

Patient's date of birth and/or age

The Bencard Medical Department will be pleased to advise on any aspect of treatment.

Product licence number 0038/5086.

AMOXIL* CAPSULES

AMOXIL* DISPERSIBLE TABLETS ▼

AMOXIL* SYRUP 125 mg

AMOXIL* SYRUP FORTE 250 mg

AMOXIL* SACHETS 3 g ▼

AMOXIL* PAEDIATRIC SUSPENSION

AMOXIL* INJECTION ▼

Presentation *Amoxil Capsules:* (Amoxycillin Capsules BP) Maroon and gold capsules overprinted 'Amoxil 250', each providing 250 mg amoxycillin.

Maroon and gold capsules overprinted 'Amoxil 500', each providing 500 mg amoxycillin.

Amoxil Dispersible Tablets: Flat, white circular tablets, engraved 'Amoxil 500', each providing 500 mg amoxycillin.

Amoxil Syrups: (Amoxycillin Mixture BP) Citrus flavoured syrup, providing 125 mg or 250 mg amoxycillin per 5 ml.

Presented as powder in bottles for preparing 100 ml.

Amoxil 3 g Sachet: Each sachet provides 3 g amoxycillin for reconstitution in approximately one third of a glass of water.

Amoxil Paediatric Suspension. Citrus flavoured suspension, providing 125 mg amoxycillin per 1.25 ml (measured by the pipette supplied).

Presented as powder in bottles for preparing 20 ml.

Amoxil Vials for Injection: Each vial provides 250 mg, 500 mg or 1 g amoxycillin. Presented as powder for reconstitution.

The amoxycillin content per dose unit is present as the trihydrate in Amoxil oral preparations and as the sodium salt in Amoxil injections.

Uses *Treatment of Infection:* Amoxil is a broad spectrum antibiotic indicated for the treatment of commonly-occurring bacterial infections such as:

Upper Respiratory Infections

Otitis media

Acute and Chronic Bronchitis

Lobar and Bronchopneumonia

Cystitis, Urethritis, Pyelonephritis

† All dosages should be reduced as required for children.

Bacteriuria in pregnancy
Gynaecological infections including puerperal sepsis and septic abortion
Gonorrhoea
Peritonitis
Intra abdominal sepsis
Septicaemia
Bacterial endocarditis
Typhoid and Paratyphoid fever
Skin and Soft Tissue Infections
Osteomyelitis

In children with urinary tract infection the need for investigation should be considered.

Oral prophylaxis of endocarditis: Amoxil may be used for the prevention of bacteraemia, associated with procedures such as dental extraction in patients at risk of developing bacterial endocarditis.

The wide range of organisms sensitive to Amoxil's bactericidal action include.

<i>Gram-positive</i>	<i>Gram-negative</i>
Streptococcus faecalis	Haemophilus influenzae
Streptococcus pneumoniae	Escherichia coli
Streptococcus pyogenes	Proteus mirabilis
Streptococcus viridans	Salmonella species
Staphylococcus aureus (penicillin-sensitive)	Shigella species
Clostridium species	Bordetella pertussis
Corynebacterium species	Brucella species
Bacillus anthracis	Neisseria gonorrhoeae
Listeria monocytogenes	Neisseria meningitidis
	Vibrio cholerae
	Pasteurella septica

Dosage and administration *Treatment of Infection:*

Adult dosage: Oral.

Standard adult dosage: 250 mg three times daily, increasing to 500 mg three times daily for more severe infections.

High dosage therapy (maximum recommended oral dosage 6 g daily in divided doses): A dosage of 3 g twice daily is recommended in appropriate cases for the treatment of severe or recurrent purulent infection of the respiratory tract.

Short course therapy: Simple acute urinary tract infection: two 3 g doses with 10–12 hours between the doses. Gonorrhoea: single 3 g dose.

Adult dosage: Injectable: 500 mg IM eight hourly (or more frequently if necessary) in moderate infections. 1 g IV six hourly in severe infections.

Children's dosage (up to 10 years of age): Oral: 125 mg three times daily, increasing to 250 mg three times daily for more severe infections.

Injectable 50–100 mg/kg body weight a day, in divided doses.

Parenteral therapy is indicated if the oral route is considered impracticable or unsuitable, and particularly for the urgent treatment of severe infection.

In renal impairment the excretion of the antibiotic will be delayed and depending on the degree of impairment it may be necessary to reduce the total daily dosage.

Oral prophylaxis of endocarditis: Adults and children over 10 years: A single 3 g dose about one hour before the procedure from which bacteraemia may arise.

N.B. Oral prophylaxis is generally inappropriate for patients who require a general anaesthetic. Prophylaxis with parenteral antibiotics may also be considered more appropriate for patients with prosthetic heart valves or pacemakers.

Children under 10 years: Half adult dosage.

Administration: Oral: Using capsules, dispersible tablets, syrups, 3 g sachets or paediatric suspension.

Intramuscular: 250 mg: Add 1.5 ml Water for Injections BP and shake vigorously.

500 mg: Add 2.5 ml Water for Injections BP and shake vigorously.

A transient pink colouration or slight opalescence may appear during reconstitution. Reconstituted solutions are normally a pale straw colour.

If pain is experienced on intramuscular injection, a sterile 1% solution of lignocaine hydrochloride or 0.5% solution of procaine hydrochloride may be used in place of Water for Injections.

Intravenous: Dissolve 250 mg in 5.0 ml Water for Injections BP.

Dissolve 500 mg in 10 ml Water for Injections BP.

Dissolve 1 g in 20 ml Water for Injections BP.

Amoxil injection, suitably diluted, may be injected directly into a vein or drip tube, taking 3–4 minutes – or added to infusion fluids, as recommended in the package enclosure leaflet, and infused over a period of ½–1 hour.

Contra-indications, warnings, etc Amoxil is a penicillin and should not be given to penicillin-hypersensitive patients.

Side-effects: Side-effects, as with other penicillins, are usually of a mild and transitory nature; they may include diarrhoea, indigestion, or occasionally rash, either urticarial or erythematous. An urticarial rash suggests penicillin hypersensitivity and the erythematous type rash may arise if Amoxil is administered to patients with glandular fever. In either case treatment should be discontinued. Since Amoxil is a penicillin, problems of overdosage are unlikely to be encountered.

Pharmaceutical precautions Prior to use, oral presentations of Amoxil should be stored in a dry place. Amoxil injections should be stored in a cool, dry place. Once dispensed, Amoxil syrups and paediatric suspension should be used within the periods stated on the labels. Any remaining syrup or suspension should be discarded.

Amoxil Injections should be prepared immediately before use. Their stability in various infusion fluids is given in the package enclosure leaflet. They should not be mixed with blood products, other proteinaceous fluids such as protein hydrolysates, or with intravenous lipid emulsions.

Legal category POM.

Package quantities Amoxil Capsules: 250 mg packs of 100 and 500. 500 mg packs of 100.

Amoxil Dispersible Tablets: 500 mg packs of 30.

Amoxil Syrups: 125 mg and 250 mg per 5 ml: 100 ml bottles.

Amoxil 3 g Sachet: Packs of 2 and 10.

Amoxil Paediatric Suspension: 125 mg per 1.25 ml: 20 ml bottles with pipette.

Amoxil Vials for Injection: 250 mg, 500 mg and 1 g: packs of 10, 10 and 5 respectively.

Further information Amoxil is well absorbed by the oral and parenteral routes. Oral administration, usually at convenient t.d.s. dosage, produces high serum levels independent of the time at which food is taken. Amoxil gives good penetration into bronchial secretions and high urinary concentrations of unchanged antibiotic. It is rapidly bactericidal and possesses the safety of the penicillins.

Sucrose content: Amoxil Syrup 3.1 g per 5 ml; Syrup Forte 2.9 g per 5 ml; Paediatric Suspension 0.6 g per 1.25 ml; Sachet 19 g. (Amoxil Capsules and Dispersible Tablets are sugar-free.)

**ASERBINE* CREAM
ASERBINE* SOLUTION**

Presentation *Aserbine Cream:* White cream in a tube.

Aserbine Solution: Clear colourless liquid in a polythene bottle.

Aserbine is prepared from:

	<i>Aserbine cream %</i>	<i>Aserbine solution %</i>
Propylene glycol	1.7	40.0
Malic acid	0.36	2.25
Benzoic acid	0.024	0.15
Salicylic acid	0.006	0.0375

Uses *Principal action:* Aserbine is a desloughing and cleansing agent which does not affect living tissue and has antibacterial properties to guard against wound infection.

Uses:

- Whenever the presence of slough delays healing:
 - Chronic skin ulcers:
 - Venous (varicose) ulcers and other benign chronic ulcers; Trophic ulcers including pressure sores.
 - Burns.
 - Traumatic injuries:
 - Crushed limb injuries; multiple lesions.
 - Surgical procedures where slough may be a problem:
 - Preparation for skin grafting; mastectomies; amputations; post-surgical incisions.
- Cleansing:
 - Wounds and abrasions where coagulum, debris, dirt and grit, etc. are a problem.

Administration Aserbine is suitable for both adults and children and should be applied topically.

For desloughing: Aserbine Cream should be applied liberally to the wound surface and before each new application the wound should be washed with Aserbine Solution so that the loose slough and cream from the previous application are removed.

Dressing the wound twice daily has been found to produce the best results; however, more frequent dressings may be made if necessary.

Aserbine Solution may also be applied as a wet dressing which should be kept constantly moist.

For cleansing: Both Aserbine Cream and Solution have proved of value as cleansing agents in casualty work for the removal of coagulum, debris, dirt, grit, etc. from wounds and abrasions.

Contra-indications, warnings, etc

Contra-indications: None.

Warning: For external use only.

Precautions: Care should be taken to avoid contact with the eyes because of Aserbine's low pH.

As Aserbine Cream contains 0.015% hexachlorophane it should not be administered except on medical advice, to a child under two years of age.

Overdosage: Not applicable.

Side-effects: Mild pyrexia, partially due to the absorption of protein products of slough breakdown from the wound, has been reported in severely burned patients. Irritation of the hypersensitive skin surrounding the wound may occur in a few patients. In these cases, Aserbine should be kept away from the growing epithelium at the periphery of the wound.

Occasionally a mild urticarial rash has been seen a small distance around the treated area. The discomfort was slight and readily controlled by antihistamines.

Pharmaceutical precautions Prolonged contact of Aserbine Solution with metallic surfaces is inadvisable.

Legal category GSL.

Package quantities *Aserbine Cream:* 100 g tube. *Aserbine Solution:* 500 ml bottle.

Further information The acid pH of Aserbine Cream and Solution is such that, when applied to a wound, it causes maximum differential swelling between the living protein of healthy tissues and the dead protein of slough, leading to the separation of the dead tissue (desloughing). The wound surface is cleared from the presence of slough and debris without affecting the living tissue so that uninterrupted normal healing can proceed. Aserbine also has antibacterial properties which guard against wound infection.

Dressings with Aserbine Cream are non-adherent, odourless and do not stain the skin, clothing, etc.

BENCARD* SKIN TESTING SOLUTIONS

Presentation Bencard Skin Testing Solutions for the diagnosis of allergy are available for over 200 allergens. Prick testing is the generally recommended method. The full range of extracts is available for inclusion in SDV (specific desensitising vaccines).

The more common allergens (marked † in the list of allergens below) are also available for inclusion in Alavac-S vaccines.

Prick tests: Aqueous allergen extracts containing 50% glycerin, 6% sodium chloride (with the exception of mould extracts, which contain < 1% sodium chloride) and 0.5% phenol as a preservative. Supplied in polythene-stoppered vials containing approximately 2 ml of solution, sufficient for about 100 individual tests.

Intradermal tests: When these are requested they will be supplied as aqueous allergen extracts in dilute phosphate buffer with 0.5% phenol as a preservative. Supplied in vials containing approximately 2 ml of sterile solution, sufficient for about 30 individual tests.

Form and appearance: The colours of individual skin testing solutions vary depending on the characteristics of the raw material involved, e.g. pollens tend to be

yellowish whilst dusts and moulds, in particular, are shades of brown.

Availability: Bencard Skin Testing Solutions are available either individually from the list specified below or as Kits (Series I and Series II) containing selections of the most important allergens.

STANDARD GROUPS OF ALLERGENS

(all allergens contained in these groups are also available individually)

† **B2 Grass pollens:** Bent; Brome; Cocksfoot; Dogstail (Crested); False oat (Oat grass); Fescue (Meadow); Foxtail (Meadow); Meadow grass; Rye grass; Timothy; Vernal (Sweet); Yorkshire fog.

† **B3 Tree pollens:** Alder; Ash; Beech; † Birch, Silver; Elm; † Hazel; Oak; Plane; † Poplar; Willow.

† **B5 Weed and shrub pollens:** Heather; † Nettle; † Plantain; Fat Hen; Mugwort; Orache.

INDIVIDUAL ALLERGENS

Dusts: Flax Dust and Fibre; † Hay; † House; † Straw; † Threshings (bran); Mixed (Barley, Maize, Oats, Wheat); Threshings (bran), Wheat.

Epithelial (feathers, fur, hair and danders): Feathers: Budgerigar; Canary; Chicken; Goose; † Mixed; Pigeon.

Fur: † Cat; Mixed (fine); (Beaver, Fox, Mink, Musquash, Squirrel); † Rabbit.

Hair: Camel; † Cow; † Dog; Goat; Guinea Pig; Hamster; † Horse; † Human; Mouse; Rat.

Pig bristle.

† Sheep wool.

Fabrics: Acrilan; † Cotton flock; Hessian (Jute); † Kapok; Linen; Nylon; Rayon; Silk; Terylene; White wool.

Flowers and foliage (mixed): Chrysanthemum (*C. morifolium*); Geranium (*Pelargonium* spp.); Grass cuttings; Primula (*Primula* spp.).

Woods (sawdust): Beech (*Fagus sylvatica*); Birch (*Betula* spp.); Cedar of Lebanon (*Cedrus libani*); Cedar, Western Red (*Thuja plicata*); Deal; (*Pinus sylvestris*); Douglas Fir (*Pseudotsuga douglasii*); Hemlock (*Tsuga heterophylla*); Iroko (*Chlorophora* spp.); Makore (*Mimusops beckelii*); Mahogany (*Khaya ivorensis*); Oak (*Quercus* spp.); Obeche (*Triplochiton scleroxylon*); Pine, Parana (*Araucaria brasiliana*); Ramin (*Gonyostylus* spp.); Teak (*Tectona grandis*).

(FOODS)

Cereals (Grain, Flour, Bread): Flour, Mixed (Plain, Self-raising and Wholewheat); Plain; Rye; Wholewheat.

Grain: Barley; Maize; Oat, Rice; Rye; Wheat.

Dairy products: Cheese, Mixed (Cheddar and Dutch); Egg Whole; Milk (Cow).

Drinks: Coffee; Tea.

Fish: Cod; Herring; Plaice; Sardine.

Shellfish: Crab; Lobster; Mussel; Oyster; Shrimp.

Fruits: Apple; Banana; Grapes (Mixed black and white); Lemon; Orange; Strawberry; Tomato.

Meats: Beef-veal; Mutton-lamb; Pork-bacon.

Nuts: Mixed (Almond, Brazil, Chestnut, Hazel and Walnut).

Vegetables: Beans, Mixed (Broad, Haricot and Runner); Cabbage; Carrot; Mushroom; Onion; Pea; Potato (New); Spinach.

Unclassified: Chocolate; Mustard; Yeast (Mixed); Yeast (Bakers).

(MICRO-ORGANISMS)

House dust mite: *Dermatophagoides farinae* (culinae); † *Dermatophagoides pteronyssinus*.

Bacteria: *Corynebacterium hofmannii*; *Escherichia coli* (*B. coli*); *Haemophilus influenzae*; *Klebsiella pneumoniae*; (*Friedlander's bacillus*); *Neisseria catarrhalis*; *Pseudomonas aeruginosa*; (*B. pyocyaneus*); *Staphylococcus aureus*; *Staphylococcus albus*; *Streptococcus Lancefield Group C*; *Streptococcus Lancefield Group G*; *Streptococcus pneumoniae* Type 1; *Streptococcus viridans*.

Fungi (moulds and yeasts): † *Alternaria alternata*; *Aspergillus amstelodami*; † *Aspergillus fumigatus*; † *Aspergillus niger*; *Aspergillus terreus*; *Botrytis cinerea*; † *Candida albicans*; *Chaetomium globosum*; † *Cladosporium herbarum*; *Epicoccum purpurascens*; † *Fusarium* spp.; † *Merulius lacrymans* (Dry rot); *Mucor mucedo*; *Mucor racemosus*; *Mucor spinosus*; † *Neurospora sitophila*; *Paecilomyces marquandii* (*Spicaria violacea*); † *Penicillium notatum*; *Phoma betae*; *Pullularia pullulans*; † *Rhizopus nigricans*; † *Sporobolomyces roseus*; † *Trichophyton (T. mentagrophytes and T. rubrum)*; *Trichophyton mentagrophytes (interdigitale)*; *Trichophyton rubrum*; *Trichophyton verrucosum*; *Ustilago*.

Insects: Bee (*Apis mellifera*); Flour beetle (*Tribolium confusum*); Mosquito (*Culex* spp.); Wasp (*Vespula* spp.).

(POLLENS)

Flower pollens: Aster (*Callistephus chinensis*); Bluebell (*Endymion non-scriptus*); Chrysanthemum (*C. morifolium koreanum*); Daffodil (*Narcissus* spp.); Dahlia (*Dahlia* spp.); Goldenrod (*Solidago canadensis*); Lupin (*Lupinus polyphyllus*); Marguerite, (*Chrysanthemum leucanthemum*); Michaelmas Daisy (*Aster novi-belgii*); Tulip (*Tulipa* spp.); Wallflower (*Cheiranthus cheiri*).

Grass pollens: Bent (*Agrostis tenuis*); Bermuda (*Cynodon dactylon*); Brome (*Bromus* spp.); Cocksfoot (*Dactylis glomerata*); Couch (*Agropyron repens*); Dogstail, Crested (*Cynosurus cristatus*); False Oat (*Arrhenatherum elatius*); Fescue, Meadow (*Festuca pratensis*); Foxtail, Meadow (*Alopecurus pratensis*); † Maize (*Zea mays*); Meadow Grass (*Poa pratensis/trivialis*); Oat, Cultivated (*Avena sativa*); Oat, Wild (*Avena fatua*); † Rye, Cultivated (*Secale cereale*); Rye-grass (*Lolium perenne/multiflorum*); Timothy (*Phleum pratense*); Vernal, Sweet (*Anthoxanthum odoratum*); Wheat, Cultivated (*Triticum* spp.); Yorkshire Fog (*Holcus lanatus*).

Shrub and tree pollens: Acacia, False (*Robinia pseudo-acacia*); Alder (*Alnus* spp.); Ash (*Fraxinus* spp.); Beech (*Fagus* spp.); † Birch, Silver (*Betula* spp.); † Elder (*Sambucus nigra*); Elm (*Ulmus* spp.); Hawthorn (*Crataegus* spp.); † Hazel (*Corylus* spp.); Heather (*Calluna vulgaris*); Horse-chestnut (*Aesculus* spp.); Laburnum (*L. anagyroides*); Lilac (*Syringa vulgaris*); Lime (*Tilia europea/cordata*); Mezquit (*Prosopis* spp.); Mock Orange (*Philadelphus* spp.); Oak, Common (*Quercus* spp.); Pine, Austrian (*Pinus nigra*); Pine Scots (*Pinus sylvestris*); Plane (*Platanus* spp.); † Poplar (*Populus* spp.); Privet (*Ligustrum* spp.); Rose (*Rosa* spp.); Sycamore (*Acer* spp.); Willow (*Salix* spp.).

Weed and miscellaneous pollens: Buttercup (*Ranunculus* spp.); Clover (*Trifolium* spp.); Dandelion (*Taraxacum* spp.); Fat Hen (*Chenopodium* spp.); Mugwort (*Artemisia vulgaris*); † Nettle (*Urtica dioica*); Orache (*Atriplex* spp.); † Plantain (*Plantago lanceolata*); Ragweed, Common or Short (*Ambrosia elatior*); Ragwort (*Senecio jacobaea*); Sorrel (*Rumex acetosa*); Willow-

herb, Rosebay (*Chamaenerion angustifolium*); Worm-wood (*Artemisia absinthium*).

SERIES I AND SERIES II KITS

The most important allergens are supplied as Series I, and the next important as Series II kits. Both kits are supplied complete with control solution, prick test instruments, Bencard Case History Charts and Skin Test Reaction Charts.

The contents are listed below:

Series I (20 prick test solutions): †House dust mite (*D. pteronyssinus*); †House dust; †Feathers; †Horse hair and dander; †Cat fur; †Dog hair; †Sheep wool; †Human hair and dandruff; †Rabbit fur; †Cotton flock; †B2 Grass pollens; †B3 Tree pollens; †B5 Weed and shrub pollens; †Hay dust; †Straw dust; †*Cladosporium herbarum*; †*Alternaria alternata*; †Plantain pollen; †Nettle pollen; †Birch pollen.

Series II (19 prick test solutions): †Cow dander; †Kapk; †*Aspergillus niger*; †*Neurospora sitophila*; †*Rhizopus nigricans*; †*Penicillium notatum*; †*Fusarium* spp.; †*Sporobolomyces roseus*; †Dry rot; †*Aspergillus fumigatus*; †Mixed threshings; †*Staph. aureus*; †Hazel pollen; Whole egg; Wheat grain; Milk; Chocolate; Cod; Lobster.

Allergens marked † in the above lists are available for inclusion in both Alavac-S and SDV vaccines.

All other allergens listed are available for inclusion in SDV only.

Bencard tries to ensure that all allergens are immediately available from stock; however, in view of the large range, this may not always be possible.

The Bencard list of allergens is continually being reviewed to reflect current practice and demand.

Uses Bencard Skin Testing Solutions are used to confirm the significance of the most likely causative allergens indicated by case history and to establish their relative importance in allergic conditions.

Dosage and administration Prick testing solutions must not be used for intradermal testing.

Recommended technique for skin testing:

1. **General information:** Adrenaline Injection BP (1 in 1000) and other supportive measures must always be kept at hand when skin testing with any allergens.

Antihistamines and other drugs which are likely to suppress the immediate Type 1 reaction should be discontinued 48 hours prior to testing.

The flexor aspect of the forearm is a convenient site for testing. Clean the skin with soap and water if necessary – do not sterilize with organic solvents or strong antiseptics.

A ball point pen may be used to mark the skin (with suitable symbols) adjacent to planned test sites to identify the allergen and control solutions used.

Since each vial is used more than once, aseptic precautions must be sufficient to avoid the risk of microbial contamination.

2. **Prick testing:** Using the applicator attached to the vial cap, place one drop of the control solution on the skin.

In the same way, place one drop of each prick test solution required at about 3 cm intervals along the arm.

Hold the prick test instrument supplied almost parallel to the skin with its tip in the drop of control solution. Push until the tip just enters the superficial skin layer taking care not to draw blood. Raise the tip slightly and then withdraw the instrument.

Repeat the procedure with each test solution, either rinsing the prick test instrument in carbol saline and wiping it between each test, or using a fresh prick test instrument.

Carefully wipe any excess test solution away using a fresh piece of sterile cotton wool for each test.

3. **Intradermal testing:** Clean the rubber cap of the testing solution vial with sterile saline or 0.5% phenol solution. Do not use spirit or other strong antiseptics.

Using a tuberculin syringe with a short bevel needle, inject 0.01 to 0.02 ml of control solution intradermally. It is important to inject into the skin and not beneath it. This will raise a small bleb.

In the same way, inject 0.01 to 0.02 ml of each intradermal test required at about 3 cm intervals along the arm.

Use either a fresh syringe or clean the syringe and needle after each test by three times drawing into it and ejecting sterile saline or 0.5% phenol solution. The three washes are best drawn from three separate beakers (which should be used in the same order after each test) and each wash discarded into a fourth beaker.

4. **Interpretation of Skin Test Reactions:** Examine reactions approximately fifteen minutes after testing. Assess the strength of each reaction by the degree of erythema and the area of the weal formed. Weal size may be measured with a Bencard Skin Test Reaction Gauge. Record the strength of each reaction relative to the control on a Bencard Skin Test Reaction Chart as follows:

Prick testing

- No weal. Erythema absent or less than 1 mm diameter.
- + Weal absent or very slight. Erythema present, not more than 3 mm diameter.
- + + Weal not more than 3 mm diameter, with associated erythema.
- + + + Weal between 3 mm and 5 mm diameter, with erythema.
- + + + + Any larger reaction, possibly with pseudopodia.

Intradermal testing

- No increase in the size of bleb since injection. No erythema.
- + An increase in the size of bleb to a weal not more than 5 mm diameter, with associated erythema.
- + + Weal between 5 mm and 8 mm diameter, with associated erythema.
- + + + Weal between 8 mm and 12 mm diameter, with erythema.
- + + + + Any larger reaction, possibly with pseudopodia.

Small positive skin test reactions no greater than that of the control solution should be ignored.

Contra-indications, warnings, etc

Prick testing solutions must not be used for intradermal testing.

Precautions: Although the likelihood of a systemic reaction is very low, Adrenaline Injection BP (1 in 1000) and other supportive measures must always be kept at hand.

Treatment of anaphylaxis: Anaphylactic shock: characterised by bronchospasm, laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.
2. 0.5 ml Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml over 15 minutes if necessary. In extreme cases, 0.5 ml Adrenaline (1 in 10,000) can be given by slow intravenous injection.
3. If bronchospasm persists, 10–20 ml of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml per minute.
4. In addition, 200–400 mg of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.
5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

Pharmaceutical precautions Bencard skin testing solutions should be stored between 2 and 8°C. Do not freeze.

Legal category POM.

Package quantities Prick and Intradermal Testing Solutions are prepared in 2ml multidose vials available individually or in Series I and II Skin Testing Kits.

Further information Nil.

Product licence number 0038/5000.

FERRAPLEX B* TABLETS

Presentation *Appearance:* Red, capsule shaped sugar-coated tablets.

Active ingredients. Each Ferraplex B tablet contains

Dried ferrous sulphate	167 mg
Copper carbonate	0.4 mg
Ascorbic acid (vitamin C)	8 mg
Thiamine hydrochloride (vitamin B ₁)	0.5 mg
Riboflavin (vitamin B ₂)	1 mg
Nicotinamide	5 mg
Dried brewers yeast	292 mg

Uses *Principal action:* Ferraplex B provides a therapeutic quantity of easily assimilable ferrous iron with other haemopoietic factors needed for maximum absorption and utilisation of iron so that haemoglobin levels are rapidly increased and maintained.

Uses: Iron deficiency anaemias associated with pregnancy and lactation, haemorrhage and menorrhagia, childhood and adolescence, old age and debility, febrile states.

Dosage and administration Ferraplex B should be taken orally.

Adults: One or two tablets three times daily, during or after meals.

Children (under 15 years of age): Reduced dosage as indicated by age and weight.

Contra-indications, warnings, etc

Contra-indications: Nil.

† All dosages should be reduced as required for children.

Warnings and precautions: Young children should not have access to iron preparations especially in the form of sugar-coated tablets, as excessive doses may be dangerous.

Side-effects: Side-effects occasionally have been reported, usually in the form of gastro-intestinal disturbances at the beginning of therapy. These upsets are usually short-lived if the dose is reduced and then gradually increased.

Overdosage: In the event of overdosage, the patient should be referred to hospital, where desferrioxamine may be administered, if required, to reduce plasma iron levels. For full details please refer to the desferrioxamine data sheet.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 250 tablets.

Further information *Iron:* Oral iron is best given in the form of inorganic ferrous salts and ferrous sulphate is one of the most stable and most easily utilised.

Copper: Copper in minute amounts promotes the utilisation of iron for the synthesis of haemoglobin appearing to act as a catalyst.

Vitamin C: Ascorbic acid influences both the absorption and utilisation of iron.

Vitamin B Complex: Members of the B complex – provided in Ferraplex B by dried brewers yeast with added thiamine hydrochloride, riboflavin and nicotinamide – have an essential role as co-enzymes in haemopoiesis.

Product licence number 0038/5088.

JUVEL* TABLETS JUVEL* ELIXIR

Presentation *Juvel Tablets:* Bright yellow, sugar-coated tablets overprinted in black with the product name JUVEL.

Juvel Elixir: Lemon-flavoured elixir.

Active ingredients

	Tablet	5 ml elixir
Vitamin A	5,000 units	4,000 units
Vitamin D ₂	500 units	400 units
Vitamin B ₁ (Thiamine hydrochloride)	2.5 mg	2 mg
Vitamin B ₂ (Riboflavin)	2.5 mg	2 mg
Vitamin B ₆ (Pyridoxine hydrochloride)	2.5 mg	2 mg
Nicotinamide	50 mg	40 mg
Vitamin C	50 mg	40 mg

Uses *Principal action:* Juvel is a balanced multivitamin dietary supplement.

Uses: As a course of multivitamin therapy, in the elderly on restricted diets; in patients on imposed dietary regimes; when impaired absorption is suspected; or when nutritional demand is greater than normal, during periods of rapid growth in childhood or adolescence and during pregnancy and lactation.

Dosage and administration For oral administration only.

Adults: 1 tablet or one 5 ml spoonful of elixir daily.
Children: over 2 years: One 5 ml spoonful of elixir daily.
Children under 2 years: 2.5 ml of elixir daily.
 (Syrup BP is a suitable diluent.)

Contra-indications, warnings, etc

Contra-indications: None at the recommended dosage.

Precautions: Care should be exercised when Juvel is co-prescribed with levodopa therapy in Parkinson's Disease since pyridoxine may antagonise the therapy.

Side-effects: None reported.

Overdosage: Prolonged ingestion of massive doses of vitamins A and D can lead to hypervitaminosis states. Symptoms include dry rough skin, painful joint swellings, anorexia and vomiting, but these disappear on withholding the vitamins.

Pharmaceutical precautions

Store in a cool place.
 The elixir should be protected from strong light and be well shaken before dispensing into amber glass containers.

Syrup BP is a suitable diluent.

Legal category

Tablets P.

Elixir GSL.

Package quantities

Tablets: 100.

Elixir: 200 ml, 1 litre.

Further information Vitamin A is required for normal epithelial growth; vitamins of the B complex for normal intracellular carbohydrate metabolism, particularly in the brain; vitamin C for the maintenance of collagen, tissue repair and blood formation; and vitamin D for metabolism of calcium and phosphorus.

Tablets 0038/5112

Elixir 0038/5111

MIGEN*

Presentation Migen contains tyrosine-adsorbed glycerinated extract of house dust mite (*Dermatophagoides pteronyssinus*).

Initial course: Six unit-dose syringes prefilled with 0.5 ml of vaccine in graded concentrations as follows:

Syringe no.	Dose: Noon Units
1	4
2	10
3	25
4	60
5	150
6	400

Maintenance course: Six unit-dose syringes prefilled with 0.5 ml of vaccine at the top dose concentration of 400 Noon units.

The tyrosine content is 4.0% w/v; with Phenol BP as a preservative.

The *D. pteronyssinus* extract is adsorbed on to tyrosine, a naturally occurring amino acid, to ensure slow release of the active material, giving a prolonged and efficient desensitising effect.

Uses Indicated for the treatment of asthma and perennial rhinitis for patients in whom house dust mite is implicated as the principal allergen.

Dosage and administration Please note that the section on 'Contra-indications, warnings, etc.' must be studied before Migen is administered.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

The administration procedures shown in the leaflet included with each course of Migen should be carefully followed.

Migen may be given to adults and children of six years and over.

Injections should be given at intervals of 7–14 days.

Migen must be removed from the refrigerator 2–3 hours before use.

The syringe should be shaken thoroughly immediately prior to giving the injection.

Injections should be given slowly by the subcutaneous route.

Do not inject into a blood vessel, or intramuscularly. Do not rub the site of injection.

Maintenance therapy: Maintenance therapy is recommended to maintain clinical improvement. The first maintenance injection should be given one month after the final injection of the initial course. Subsequent maintenance injections should be given monthly, with review at appropriate intervals, at the discretion of the physician.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from febrile conditions or an acute attack of asthma should not be given an injection until 24 hours after the condition has subsided. It is advisable to avoid use during pregnancy, especially in the first trimester.

Precautions: Patients should be warned not to eat a heavy meal immediately before an injection is due to be given.

In very sensitive patients, it is advantageous to give an antihistamine tablet about one hour before each injection.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

All patients should be instructed to remain under observation in the surgery for at least 20 minutes after each injection and advised to contact the doctor immediately in the unlikely event of a delayed reaction.

The patient should not take any strenuous physical exercise for several hours following the injection.

Reactions: Local reactions, such as slight swelling or irritation, can sometimes occur and may require symptomatic treatment if they persist.

Mild systemic reactions such as rhinitis or urticaria may be treated with antihistamines orally, or by injection if necessary. In mild bronchospasm, a sympathomimetic bronchodilator such as salbutamol and possibly an anti-inflammatory steroid should be given. If required, 0.5 ml Adrenaline Injection BP (1 in 1,000) may be given subcutaneously.

Severe systemic reactions may occasionally arise in the form of typical allergic symptoms; anaphylaxis is rare.

Treatment of anaphylaxis: Anaphylactic shock: characterised by bronchospasm, laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.

† All dosages should be reduced as required for children.

2. 0.5 ml† Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml† over 15 minutes if necessary. In extreme cases, 0.5 ml† Adrenaline (1 in 10,000) can be given by slow intravenous injection.

3. If bronchospasm persists, 10–20 ml† of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml† per minute.

4. In addition, 200–400 mg† of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.

5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

† All dosages should be reduced as required for children.

Note: A severe local reaction, or severe systemic reaction such as urticaria or asthma, indicates that the standard vaccine is unsuitable for the treatment of the particular patient, who should be referred to a consultant for advice or transferred to a suitably dilute specific desensitising vaccine (Alavac-S or SDV) containing house dust mite obtainable from Bencard.

(For full prescribing information please refer to the relevant data sheets).

Legal category POM.

Pharmaceutical precautions Migen must be stored in a refrigerator (5°C). It must not be frozen and must be removed 2–3 hours before use.

Package quantities Initial and Maintenance courses each consist of a set of 6 unit-dose syringes prefilled with vaccine, and with needles attached. An instruction leaflet is included with each set.

Further information Migen is a standard vaccine prepared from extract of *Dermatophagoides pteronyssinus*, the predominant species of house dust mite occurring in British homes. The house dust mite is the most commonly implicated allergen in allergic asthma and perennial rhinitis.

Desensitisation with Migen offers a fundamental approach to the management of the mite allergic patient. It should be prescribed when the mite has been implicated as the principal allergen by case history, and preferably confirmed by skin-testing. An appropriate testing solution is available from Bencard.

Patients who benefit from an Initial course of treatment are likely to maintain their clinical improvement with Maintenance therapy.

Migen may be prescribed on NHS form FP10. Both Initial and Maintenance courses are available for immediate supply from stock.

The Bencard Medical Department will advise on any aspect of treatment.

Product licence number 0038/0112.

NORVAL*

Presentation *Norval tablets:* Orange film coated
tablets engraved 'Norval' on one side and '30' on the
other. Each tablet contains 30 mg mianserin
hydrochloride.

Also available, orange film coated tablets containing
10 mg and 20 mg mianserin hydrochloride. Each tablet
is engraved 'Norval' on one side and '10' or '20'
respectively on the reverse.

Uses Symptoms of depressive illness.

Dosage and administration *For oral administration:*
The tablets should be swallowed whole without chewing.

Adults: Treatment should normally be initiated, for the
first few days, at 30–40 mg a day as a single bedtime
dose, or in divided doses. The effective maintenance
dosage will normally lie between 30 mg and 90 mg a day
as indicated in the table, though higher levels may be
required in some patients.

<i>Degree of depression</i>	<i>Usual daily dosage</i>
Mild to moderate	30–60 mg nocte or in divided doses
Moderate to severe	60–90 mg nocte or in divided doses. If higher levels are re- quired these should be given in divided doses.

Divided daily dosages up to 200 mg are well tolerated.

It is often advantageous to maintain antidepressant
treatment for several months after initial clinical improve-
ment has occurred.

Elderly: Not more than 30 mg a day initially. This starting
dose should be increased with caution under close
supervision. A lower maintenance dosage than is usual
may be sufficient to produce a satisfactory clinical
response.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: Use is contra-indicated in mania,
severe liver disease and during breast feeding. (Breast
feeding should be discontinued if antidepressant therapy
is considered essential.)

Use in pregnancy: Do not use during pregnancy unless
there are compelling reasons. There is no evidence of
safety in human pregnancy. Animal studies have not
shown hazard.

Precautions: Care should always be taken in patients
with recent myocardial infarction or heart block. How-
ever, serious cardiotoxic effects appear to be rare at
therapeutic dosage, even in patients with pre-existing
cardiac disease, recent myocardial infarction or cardiac
insufficiency.

The elderly are less liable to experience adverse
reactions such as agitation, confusion and postural
hypotension with Norval, than with tricyclics or bridged

tricyclics, but all antidepressant therapy should be used with caution in this group of patients.

Patients posing a high suicide risk always require close initial supervision.

Avoid, if possible, in patients with epilepsy. When treating patients with diabetes, hepatic or renal insufficiency, normal precautions should be exercised and the dosages of any concurrent therapy kept under review. Patients with narrow angle glaucoma or symptoms suggestive of prostatic hypertrophy, should also be monitored even though anticholinergic side-effects are not anticipated with Norval therapy.

There are indications that Norval, like other antidepressants, may precipitate hypomania in susceptible subjects with bipolar affective illness.

Norval may potentiate the central nervous depressant action of alcohol.

If surgery is necessary during Norval therapy, the anaesthetist should be informed of the treatment being given.

Drug interactions: Norval should not be given concurrently with, or within two weeks of cessation of therapy with, monoamine oxidase inhibitors.

Clinical experience has shown that Norval does not interact with the antihypertensives bethanidine, clonidine, hydralazine, guanethidine and propranolol. Nevertheless, the monitoring of blood pressure is recommended for those patients receiving concurrent antihypertensive therapy.

Phenytoin plasma levels should be monitored in patients treated concurrently with Norval.

Concurrent anticoagulant therapy of the coumarin-type (e.g. warfarin) is also permissible, but close additional monitoring should be undertaken.

Interactions have not been reported between Norval and sympathomimetic agents and are unlikely.

Warnings and adverse effects: As improvement may not occur during the first 2–4 weeks of treatment, patients should be closely monitored during this period. It may be advisable to maintain treatment for several months after initial clinical improvement has occurred.

The most commonly occurring side-effect is drowsiness, particularly during the first few days of therapy. Patients should be warned of the possible hazard in driving or operating machinery. Any drowsiness may be potentiated by alcohol.

Serious adverse effects are uncommon. A small number of cases of bone marrow depression, usually presenting as a neutropenia, generally reversible on stopping treatment, have been reported. If a patient develops symptoms of infection, e.g. fever, sore throat or stomatitis, during treatment with Norval, treatment must be stopped and a full blood count obtained.

Jaundice, usually mild, hypomania and convulsions have also been reported at therapeutic dosage and under such circumstances treatment should be withdrawn.

Additional adverse effects that may occur include breast disorders (gynaecomastia, nipple tenderness and non-puerperal lactation), dizziness, postural hypotension, polyarthropathy, skin rash, sweating and tremor.

Psychotic manifestations including mania and paranoid delusions may be exacerbated during antidepressant therapy.

The following adverse effects although not reported with Norval can occur with tricyclics and bridged tricyclics: interference with sexual function; withdrawal symptoms in adults; withdrawal symptoms (e.g. neuromuscular irritability) in neonates whose mothers received

tricyclic or bridged tricyclic pregnancy.

Overdosage: There is no spe by gastric lavage with appr Symptoms of overdosage prolonged sedation. Cardiac tension, convulsions and unlikely to occur.

Pharmaceutical precauti light.

Legal category POM.

Package quantities Norva in foil packs of 30. Each pack of 10 tablets. Also available in tablets. Norval 10 mg tablet of 90 (three blister strips of 3 and 500 tablets. The 20 containers of 100.

Further information Nor a distinctive tetracyclic struc ant benefits over the tricyclic also been shown to possess parable with diazepam.

Antidepressant activity is amitriptyline and imipramine, for its absence of troubles effects; this may be of spec depressed patients who may conditions such as glauco prostatic hypertrophy. There that anticholinergic effects s psychosomatic feature of deJ toms have been shown to therapy. Clinical experience is significantly less toxic tl imipramine and that cardiac p appears to be particularly ef mistic thought' and 'suicid relatively high safety margir tance in view of the high nu to tricyclic overdosage.

Heavy magnesium oxide

Calcium carbonate

Heavy magnesium carbonate

Peppermint oil q.s.

Calorific content per tablet:

Uses *Principal action:* The antacids and milk protein i continuous neutralisation of the gastric acidity is maintai

The milk fat in Nulacin help excess gastric juice.

Uses: Dyspepsia. Reflux o Peptic ulcer. Whenever gastr

Dosage and administration One or more tablets as required.

For continuous therapeutic effect the tablet should be allowed to dissolve slowly in the mouth, placed between cheek and gum. For quicker relief the tablet should be chewed and swallowed.

Contra-indications, warnings, etc

Contra-indication: As Nulacin contains gluten, it is contra-indicated in coeliac disease.

Warnings and precautions: Nil.

Side-effects: No significant side-effects have been encountered with Nulacin.

Overdosage: Overdosage has not been reported. However, as with all antacids, there is a theoretical danger of alkalosis.

Pharmaceutical precautions Store in a cool dry place. Replace cap of securitainer after use.

Legal category GSL.

Package quantities 100 tablets.

Further information Nulacin contains effective doses of antacids to give rapid relief from gastric pain. Nulacin dissolves slowly in the mouth to give continuous relief which is independent of the rate of stomach emptying. Nulacin is presented in convenient tablets which have a very acceptable malt and mint flavour.

Product licence number 0038/5079.

OROVITE[®] TABLETS
OROVITE[®] ELIXIR

Presentation *Orovite Tablets:* Maroon, sugar-coated tablets overprinted in white with the product name 'OROVITE'.

Orovite Elixir: Orange-flavoured elixir.

Active ingredients

	Tablet (mg)	5 ml elixir (mg)
Thiamine hydrochloride (vitamin B ₁)	50	20
Riboflavin (vitamin B ₂)	5	2
Pyridoxine hydrochloride (vitamin B ₆)	5	2
Nicotinamide	200	80
Ascorbic acid (vitamin C)	100	40

Uses *Principal action:* Orovite contains high concentrations of the water-soluble vitamins B and C to correct disturbed carbohydrate metabolism.

Uses: Deficiency of the B complex and C vitamins, in particular when encountered: (a) in association with alcoholism, as maintenance therapy; (b) as debility after febrile illnesses such as influenza, measles; acute bronchitis, tonsillitis, enteritis, viral pneumonia; (c) in constitutional states in old age or following illness; (d) as debility following operation.

Orovite is also useful as oral maintenance therapy following a course of Parentrovite. (See Parentrovite data sheet.)

Dosage and administration For oral administration only.

Adults: One tablet or two 5 ml spoonfuls elixir three times a day.

Children: One 5 ml spoonful elixir three times a day. (Syrup BP is a suitable diluent.)

If parenteral therapy is required, treatment should be commenced with Parentrovite.

Contra-indications, warnings, etc

Contra-indications: Nil.

Precautions: Care should be exercised when Orovite is co-prescribed with levodopa therapy in Parkinson's Disease since pyridoxine may antagonise the therapy.

Side-effects: Rarely, flushing of the face may occur.

Overdosage: Nil.

Pharmaceutical precautions Store in a cool place. The elixir should be protected from strong light and be well shaken before dispensing into amber glass containers.

Syrup BP is a suitable diluent.

Legal category GSL.

Package quantities *Tablets:* 25, 100, 500.

Elixir, 200 ml, 1 litre.

Further information Vitamins of the B complex play an integral part as co-enzymes in many stages of the intracellular metabolism of carbohydrates. The efficient functioning of this metabolism is essential for normal health. Similarly, ascorbic acid plays an important part in the biochemical reactions of cells and tissues and is normally present in the highest concentrations in those parts of the brain which are the most active metabolically.

Lack of water soluble vitamins results in impairment of normal intracellular metabolism and may lead to certain disorders (see uses). The high concentrations of the water soluble vitamins contained in Orovite rapidly replenish depleted cellular stores and speed the return of normal intracellular metabolism.

Tablets 0038/5092
Elixir 0038/5091

OROVITE '7'

Presentation Orange coloured granules in unit dose sachets.

Active ingredients: Each sachet contains:

Vitamin A (Palmitate)	2,500 units
Vitamin D ₂	100 units
Vitamin B ₁ (Thiamine Mononitrate)	1.4 mg
Vitamin B ₂ (as Riboflavin)	
Sodium Phosphate)	1.7 mg
Vitamin B ₆ (Pyridoxine Hydrochloride)	2.0 mg
Nicotinamide	18 mg
Vitamin C	60 mg

Uses Orovite '7' provides a course of balanced multivitamin therapy for the management of potential vitamin deficiencies.

Dosage and administration For oral administration only.

Adults and children over 5 years of age: The contents of one sachet per day, dissolved in approximately one third of a tumbler of water.

Contra-indications, warnings, etc

Contra-indications: None at the recommended dosage.

Precautions: Care should be exercised when Orovite '7' is co-prescribed with levodopa therapy in Parkinson's Disease since pyridoxine (Vitamin B₆) may antagonise the therapy.

Side-effects: None reported.

Overdosage: Prolonged ingestion of massive doses of vitamins A and D can lead to hypervitaminosis states. Symptoms include dry rough skin, painful joint swellings, anorexia and vomiting; these disappear when treatment is discontinued.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities Thirty sachets.

Further information Orovite '7' provides adequate intake of essential vitamins for patients whose daily nutritional requirements may not be met, such as the elderly on restricted diets, patients on imposed dietary regimes, or in cases where impaired absorption is suspected.

Orovite '7' has a convenient and palatable once-daily sachet presentation which improves patient compliance and is especially suitable for patients who may have difficulty in swallowing tablets or measuring doses from bottles.

Product licence number 0079/0164.

PARENTROVITE* IVHP

PARENTROVITE* IMHP

PARENTROVITE* IMM

Presentation Paired amber glass ampoules for injectable administration in three different presentations. Intravenous High Potency (IVHP), Intramuscular High Potency (IMHP) and Intramuscular Maintenance (IMM).

Active ingredients: See table on next page.

Uses *Principal action:* Parentrovite IVHP, IMHP and IMM contain exceptionally high concentrations of the water-soluble vitamins B and C to correct disturbed carbohydrate metabolism.

Uses: Deficiency of the B complex and C vitamins, in particular that encountered: (a) in association with alcoholism; (b) in peripheral neuritis, associated with malabsorption syndromes, alcoholism or diabetic neuropathy; (c) after acute febrile illness, e.g. influenza, pneumonia; (d) in confusional states following severe illness or operation, especially in the elderly; (e) in states of acute malnutrition.

Dosage and administration

Indication	Dosage
(a) In association with alcoholism – acute alcoholic psychosis – delirium tremens – coma or delirium – post-operative confusional states.	2 to 4 pairs Intravenous High Potency ampoules, repeated 4 to 8 hourly for up to 2 days as indicated clinically, followed by 1 pair Intravenous High Potency or Intramuscular High Potency ampoules daily for 5 to 7 days.

Indication	Dosage
(b) Peripheral neuritis associated with malabsorption states, alcoholism or diabetic neuropathy.	1 pair Intravenous High Potency or Intramuscular High Potency ampoules, once or twice daily for 3 to 7 days.
(c) After acute febrile illness	1 to 2 pairs Intramuscular Maintenance ampoules daily.
(d) In confusional states following severe illness especially in the elderly.	"
(e) In states of acute malnutrition.	"
Maintenance therapy for longer term treatment of the above conditions.	1 to 2 pairs Intramuscular Maintenance ampoules daily, until full health is restored, or until continuation therapy by oral route is possible (e.g. with Orovite tablets).

Children: Parenteral therapy is rarely necessary as children usually respond well to oral administration of the vitamin B complex in high dosage: e.g. with Orovite elixir. (See Orovite data sheet.) However, when parenteral administration of vitamins is required, the following dosage guidelines are recommended;

6–10 years: $\frac{1}{2}$ adult dose,

10–14 years: $\frac{2}{3}$ to $\frac{1}{2}$ adult dose.

14 years and over: adult dose.

These dosages may have to be modified in individual cases.

Administration: For parenteral administration only.

The contents of each pair of ampoules (i.e. No. 1 and No. 2) should be mixed together in a single syringe immediately prior to administration.

The intramuscular presentations must not be given intravenously. The intravenous presentation must not be given intramuscularly. When given by infusion with other drugs, Parentrovite should be injected into the drip tubing immediately after mixing.

Intravenous Parentrovite – Contents of each pair of ampoules to be mixed in the syringe before injecting slowly into a vein. Dilution with normal saline may be made for drip infusion.

Intramuscular Parentrovite – Contents of each pair of ampoules to be mixed in the syringe before injecting slowly into the lateral muscles of the thigh or into the gluteal region.

Contra-indications, warnings, etc

Contra-indications: Sensitivity to any of the vitamin: present.

Warnings and Precautions: On very rare occasions: repeated injections of preparations containing high concentrations of thiamine may give rise to anaphylactic shock. Should this occur, appropriate measures, such as the injection of adrenaline and soluble gluco-corticoid: (e.g. hydrocortisone) or anti-histamine preparation: must be taken immediately. Care should be exercised when Parentrovite is co-prescribed with levodopa: therapy in Parkinson's Disease, since pyridoxine may antagonise the therapy.

Side-effects: Flushing of the face has been reported occasionally.

Overdosage: Effects of overdosage are rare. It has been reported, however, that following administration of very large doses (for example over 10 pairs IVHP daily for three or more days) a state of excitement can result which is characterised by rapid, though rational, mental activity. This subsides within 24 hours of stopping treatment, and there is often amnesia for the episode.

Pharmaceutical precautions Store in a cool place.

IM High Potency: 3 pairs, 12 pairs.

IM Maintenance: 3 pairs, 24 pairs.

Further Information Vitamins of the B complex play an integral part as co-enzymes in many stages of the intracellular metabolism of carbohydrates. The efficient functioning of this metabolism is essential for normal health. Similarly, ascorbic acid plays an important part in the biochemical reactions of cells and tissues and is normally present in the highest concentrations in those parts of the brain which are the most active metabolically.

Lack of the water soluble vitamins results in impairment of normal intracellular metabolism and may lead to certain disorders (see uses). In some cases, such as an alcoholic who develops Wernicke's encephalopathy, lack of immediate treatment can result in permanent brain damage or even death.

The very high concentrations of the water-soluble vitamins contained in Parentrovite, rapidly replenish depleted cellular stores and speed the return of normal metabolism.

POLLINEX*

Presentation Pollinex contains glutaraldehyde-modified extracts of pollen from twelve varieties of common grasses (Bent, Brome, Cocksfoot, Crested Dogtail, False Oat, Fescue, Meadow Foxtail, Meadow-grass, Rye-grass, Timothy, Vernal and Yorkshire Fog) adsorbed on to tyrosine.

Each course of treatment is presented in three unit-dose syringes each prefilled with 0.5 ml of vaccine in graded concentrations as follows:

Syringe no.	Dose: Noon Units
1	300
2	800
3	2,000

The tyrosine content is 4.0% w/v, with Phenol BP as a preservative. The grass pollen extract is modified by glutaraldehyde and adsorbed onto tyrosine, a naturally occurring amino acid, to ensure slow release of the active material, giving a prolonged and efficient desensitising effect.

Uses Indicated for the treatment of classical hayfever and pollen asthma, to give long-term protection whenever grass pollens are considered to be the sole or predominant cause.

Pollinex is formulated from the pollens of twelve common grasses which are responsible for the majority of classical hayfever and pollen asthma cases, and provides a convenient and effective preventive treatment.

Dosage and administration Please note that the section on 'Contra-indications, warnings, etc.' must be studied before Pollinex is administered.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

The administration procedures shown in the leaflet included with each course of Pollinex should be carefully followed.

The course should normally be started by mid-April (in the U.K.) in order to ensure completion before the onset of the grass pollen season. Do not use during the grass pollen season.

Pollinex may be given to adults and children of six years and over. Injections should be given at intervals of 7–14 days. Pollinex must be removed from the refrigerator 2–3 hours before use. The syringe should be shaken thoroughly immediately prior to giving the injection. Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

The three graduated doses of Pollinex constitute a complete course for one year. The administration of an initial course of treatment should produce a significant improvement during the ensuing pollen season. For

continued clinical improvement, it is recommended that a course should be given in each of three successive years.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from febrile conditions or an acute attack of asthma should not be given an injection until 24 hours after the condition has subsided.

It is advisable to avoid use during pregnancy, especially in the first trimester.

Precautions: Patients should be warned not to eat a heavy meal immediately before an injection is due to be given.

In very sensitive patients, it is advantageous to give an antihistamine tablet about one hour before each injection.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

All patients should be instructed to remain under observation in the surgery for at least 20 minutes after each injection and advised to contact the doctor immediately in the unlikely event of a delayed reaction.

The patient should not take any strenuous physical exercise for several hours following the injection.

Reactions:

Local reactions, such as slight swelling or irritation, can sometimes occur and may require symptomatic treatment if they persist.

Mild systemic reactions such as rhinitis or urticaria may be treated with antihistamines orally, or by injection if necessary. In mild bronchospasm, a sympathomimetic bronchodilator such as salbutamol and possibly an anti-inflammatory steroid should be given. If required, 0.5 ml Adrenaline Injection BP (1 in 1,000) may be given subcutaneously.

Severe systemic reactions may occasionally arise in the form of typical allergic symptoms; anaphylaxis is rare.

Treatment of anaphylaxis:

Anaphylactic shock: characterised by bronchospasm, laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.
2. 0.5 ml† Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml† over 15 minutes if necessary. In extreme cases, 0.5 ml† Adrenaline (1 in 10,000) can be given by slow intravenous injection.
3. If bronchospasm persists, 10–20 ml† of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml† per minute.
4. In addition, 200–400 mg† of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.
5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

Note: A severe local reaction, or severe systemic reaction such as urticaria or asthma, indicates that the standard

vaccine is unsuitable for the treatment of the particular patient, who should be referred to a consultant for advice or transferred to a suitably dilute specific desensitising vaccine (Alavac-S or SDV) obtainable from Bencard. (For full prescribing information please refer to the relevant data sheets.)

Pharmaceutical precautions Pollinex must be stored in a refrigerator (5°C). It must not be frozen and must be removed 2–3 hours before use.

Legal category POM.

Package quantities Each course of treatment consists of a set of 3 unit-dose syringes prefilled with vaccine, and with needles attached. An instruction leaflet is included with each set.

Further information Pollinex is a short-course 3-injection vaccine which offers a practical and more permanent alternative to temporary palliatives.

Pollinex may be prescribed on the basis of case history and clinical symptoms alone, providing these reveal marked seasonality corresponding with the grass pollen season. Pollinex is prescribable on NHS form FP10 and is available for immediate supply from stock.

The Bencard Medical Department will be pleased to advise on any aspect of treatment.

Product licence number 0038/0111.

PREGNAVITE FORTE* F

Presentation Lilac, sugar-coated tablets, overprinted (FP) in white.

Active ingredients

	Each tablet contains	Hence daily dose (1 tab. three times a day) provides
Vitamin A	1,333 units	4,000 units
Vitamin D ₂	133 units	400 units
Thiamine hydrochloride (vitamin B ₁)	0.5 mg	1.5 mg
Riboflavin (vitamin B ₂)	0.5 mg	1.5 mg
Pyridoxine hydrochloride (vitamin B ₆)	0.33 mg	1.0 mg
Nicotinamide	5.0 mg	15 mg
Ascorbic acid (vitamin C)	13.3 mg	40 mg
Dried ferrous sulphate (equiv. to 25.2 mg Fe)	84 mg	252 mg (equiv. to 75.6 mg Fe)
Calcium phosphate	160 mg	480 mg
Folic acid	0.12 mg	0.36 mg

Uses *Principal action:* Pregnavite Forte F is a balanced dietary supplement containing vitamins including folic acid, with iron and calcium.

Uses: Provision of vitamin and mineral support in pregnancy. Prevention of iron and folic acid deficiency anaemia in pregnancy.

Dosage and administration For oral administration only.

Adults: 1 tablet three times daily, during or after meals.

Children: Pregnavite Forte F is not suitable for children.

Contra-indications, warnings, etc

Contra-indications: Pernicious anaemia.

Side-effects: These are rare with Pregnavite Forte F but

† All dosages should be reduced as required for children.

and mild gastro-intestinal

in children.

On overdosage, the patient should be given desferrioxamine to reduce plasma iron to the desferrioxamine

recommended doses of vitamins A and B₁₂. Symptoms include joint swellings, anorexia and weight loss on discontinuation of

Store in a cool dry

10.

Protonix Forte F provides in addition folic acid, iron in an easily absorbed form, for the effective treatment of iron deficiency in pregnancy. It should be written in full on the prescription but without a signature.

and dyspepsia; nausea and reflux oesophagitis.

For hyperacidity, dyspepsia, heartburn. One or two

tablets every hour.

Take one hour as required. Effect 1 tablet at a time

should be allowed to dissolve in the sulcus between the lower jaw and the cheek.

For extra rapid relief tablets may be chewed and swallowed.

Contra-indications, warnings, etc

Contra-indications: Nil.

Warnings and precautions: Nil.

Side-effects: No significant side-effects have been encountered with Protonix.

Overdosage: Overdosage has not been reported.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities 30 tablets. 240 tablets.

Further information Protonix is a fast-acting buffer antacid which gives relief within minutes of placing a tablet on the tongue.

Protonix tablets are conveniently small and have a pleasant peppermint taste.

Product licence number 0038/5082.

SDV

(Specific Desensitising Vaccine)

Presentation SDV is an aqueous desensitising vaccine consisting of an individually formulated set of multidose vials of allergen extracts in graded concentrations. The No. 1 and No. 2 vials are 1/64th and 1/8th dilutions respectively of the No. 3 vial.

SDV courses are available in various strengths (full, half, quarter, eighth) to meet each particular patient's requirements. If required, special reduced strength courses can also be provided. (See 'Dosage and Administration'). When a vaccine is ordered for any patient with severe symptoms of allergy or any history of asthma a Special Dilution Vial (No. 0, Black label, 1/16th dilution of the No. 1 vial) will be provided automatically (except in cases where a special reduced strength course is supplied) and should be used to initiate therapy. Special Dilution Vials are also available on request for other patients.

The allergen extracts are incorporated in a base of physiological saline with Phenol BP 0.5% w/v as preservative.

Each course of SDV is specially prepared for an individual patient in accordance with the information on causative allergens revealed by case history and skin testing and recorded on Skin Test Reaction Charts or with orders.

For the best clinical results with SDV, no more than 6 allergens should normally be included (with a maximum of 8) in any one course.

If the patient is sensitive to more than eight allergens, those which can be avoided without undue inconvenience should be omitted, and the patient given advice on avoidance; otherwise two separate vaccines will be prepared.

Over 200 standard allergen extracts, including House Dust Mite, are available for inclusion and are listed in the Bencard Skin Testing Solutions Data Sheet.

Uses To provide fundamental treatment for a wide variety of common allergic conditions such as asthma, perennial rhinitis, hayfever and some skin conditions.

Dosage and administration Please note that the section on 'Contra-Indications, Warnings, Etc.' must be studied before SDV is administered.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

The administration procedures shown in the leaflet included with each course of SDV should be carefully followed.

In the dosage schemes which follow, all injections should be given at intervals of 3–7 days, unless otherwise stated.

These schemes should be followed for all SDV patients, irrespective of the course strength selected.

The vial should be shaken thoroughly immediately prior to withdrawing a dose.

Sterile syringes should always be used for the withdrawal of doses. Since each vial is used more than once, aseptic precautions must be sufficient to avoid the risk of microbial contamination.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

If a reaction occurs, the dosage should be adjusted accordingly (see Contra-indications, warnings etc).

SDV: Selection of course strength.

The strength of course should be selected according to the patient's previous history of asthma and severity of allergic symptoms as outlined below. When in doubt, the lowest strength course should be selected, or consultant advice sought.

Adults (aged 15 years or over):

<i>Clinical condition</i>	<i>Course strength</i>
Severe symptoms of allergy (e.g. eczema) or any history of asthma	Quarter
Moderate symptoms of allergy with no history of asthma	Half
Mild symptoms of allergy with no history of asthma	Full

Children:

Alavac-S (specific vaccine-alum adsorbed allergens) is normally preferred to SDV for the treatment of children. Please refer to the product data sheet for prescribing information. SDV may be considered when a vaccine containing allergens which are not included in the Alavac-S range is required. In such cases the following dosage schemes are recommended.

8–14 years:

<i>Clinical condition</i>	<i>Age</i>	<i>Course strength</i>
Severe symptoms of allergy (e.g. eczema) or any history of asthma	8–14	Consultant advice should be sought. If treatment is required a course of one-eighth strength or lower (special reduced strength) can be provided
Moderate symptoms of allergy with no history of asthma	8–11	Eighth
	12–14	Quarter
Mild symptoms of allergy with no history of asthma	8–11	Quarter
	12–14	Half

Under 8 years:

The use of SDV for children is not recommended by B. Consult consultant advice, treat specially reduced strength provided, with a dosage individual patient's requirements.

SDV: Dosage recommendations not contain pollen allergen:

Treatment should be given. Should be timed to end the patient's seasonal sensitivity. May for grass pollen sensitivity. For tree pollen sensitivity, treatment it is recommended each of three successive

Recommended dosage, not contain pollen allergen.

Not to be used during treatment

Commence with the first course and proceed to the No. 2 (B label) vial as indicated

If a reaction occurs, the dosage should be reduced: see 'Adjustment of dosage'

<i>Vial Number*</i>	<i>Injections</i>
1. Green label	1 2 3 4 5 6
2. Buff label	7 8 9 10 11 12
3. Red label	13 14 15 16 17 18

*When a Special Dilution is initiated, treatment, dosage provided in an accompanying leaflet.

Surplus vaccine may be used in the next season.

Extended treatment: onset of the pollen season it may be beneficial to fortnightly intervals, 4 weeks before the pollen season.

SDV: Dosage recommendations not contain pollen allergen:

Courses may be given in the following order:

Commence with the first course and proceed to the No. 2 (B label) vial as indicated

If a reaction occurs, the dosage should be reduced: see 'Adjustment of dosage'

Injection Number	Dosage
	0.1 ml 0.2 ml 0.3 ml 0.5 ml 0.7 ml 1.0 ml
	0.1 ml 0.2 ml 0.3 ml 0.5 ml 0.7 ml 1.0 ml
	0.1 ml 0.2 ml 0.3 ml 0.5 ml 0.7 ml 1.0 ml

/ial (No. 0, Black label) is supplied to instructions relating to its use are on leaflet.

ment following the initial course is

for use only with vaccines which

which consists of a series of recommended particularly for

patients with perennial symptoms provided that the initial treatment course has been well tolerated.

Maintenance therapy should commence between 1 and 2 weeks after completion of the initial course and should follow the dosage scheme below. Treatment may be continued at the discretion of the physician, with review at appropriate intervals.

Maintenance Dosage Schemes. (See tables.)

N.B. Care must be taken when administering the first injection from a new No. 3 vial as in a small number of cases, a local or general reaction may occur. If a reaction occurs during treatment, dosage should be reduced: see 'Adjustment of Dosage'.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from a febrile condition or an acute attack of asthma should not be given an injection until 24 hours after the condition has subsided.

It is advisable to avoid use during pregnancy, especially in the first trimester.

Precautions: Patients should be warned not to eat a heavy meal immediately before an injection is due to be given.

In very sensitive patients it is advantageous to give an antihistamine tablet about one hour before each injection.

Injections should be given slowly by the subcutaneous route. Do not inject into a blood vessel or intramuscularly. Do not rub the site of injection.

Adrenaline Injection BP (Adrenaline 1 in 1,000) should always be kept at hand when giving any desensitising vaccine.

Maintenance Therapy: (using No. 3 vial supplied with Initial Course).

Interval Since Previous Injection*	Dosage (ml) (From No. 3 Vial)	Duration
1-2 weeks after completion of Initial Course	1.0 ml (or maximum tolerated dose if lower)	Continue until contents of No. 3 vial are exhausted.
1 week	1.0 ml (or maximum tolerated dose if lower)	Then introduce new No. 3 vial as described below.

Maintenance Therapy: Dosage scheme to be followed when introducing a new No. 3 vial.

Interval Since Previous Injection*	Dosage (ml) (From No. 3 Vial)	Duration
1 week	0.1 ml	Maintenance therapy may be continued at the discretion of the physician, with review at appropriate intervals.
1 week	0.2 ml	
1 week	0.4 ml	
1 week	0.8 ml	
1 week	1.0 ml	
2 weeks	1.0 ml	
4 weeks	1.0 ml

ist be modified as follows:

has elapsed treatment may be resumed with caution, using the dosage scheme specified above for the vial.

e elapsed since the previous injection, it is advisable not to attempt maintenance therapy but to re-start with commencing with the lowest strength (No. 1, green label) vial.

se for use with pollen-containing vaccines.

All patients should be instructed to remain under observation in the surgery for at least 20 minutes after each injection and advised to contact the doctor immediately in the unlikely event of a delayed reaction.

The patient should not take any strenuous physical exercise for several hours following the injection.

Reactions: (see also 'Adjustment of Dosage'):

Local reactions, such as slight swelling or irritation, can sometimes occur and may require symptomatic treatment if they persist.

Mild systemic reactions such as rhinitis or urticaria may be treated with antihistamines orally, or by injection if necessary. In mild bronchospasm, a sympathomimetic bronchodilator such as salbutamol and possibly an anti-inflammatory steroid should be given. If required, 0.5 ml Adrenaline Injection BP (Adrenaline 1 in 1,000) may be given subcutaneously.

Severe systemic reactions may occasionally arise in the form of typical allergic symptoms; anaphylaxis is rare.

Treatment of anaphylaxis:

Anaphylactic shock: characterised by bronchospasm, laryngeal oedema, urticaria and shock. Immediate attention should be given as follows:

1. The patient should be laid down and treated immediately.
2. 0.5 ml Adrenaline Injection BP (Adrenaline 1 in 1,000) should be given intramuscularly close to the vaccine injection site. This should be repeated to a total of 2 ml over 15 minutes if necessary. In extreme cases, 0.5 ml Adrenaline (1 in 10,000) can be given by slow intravenous injection.
3. If bronchospasm persists, 10–20 ml of Aminophylline Injection BP (250 mg per 10 ml) should be given by slow intravenous injection at a rate of 2 ml per minute.
4. In addition, 200–400 mg of Hydrocortisone Injection BP should be given intravenously. This is to combat persistent bronchospasm which can occur 6–8 hours after the initial collapse.
5. Full supportive measures should be available and employed if necessary and patients should be closely monitored for at least 24 hours after recovery.

Adjustment of Dosage (in the event of the occurrence of a reaction):

Reaction to the first injection:

If the patient has a significant reaction to the first dose from the No. 1 vial, the complete course should be returned direct to Bencard. A Special Dilution vial (No. 0-Black label; 1/8th dilution of the No. 1 vial) will be prepared free of charge and returned with a complete new course.

Treatment should recommence from the dilute vial according to the dosage scheme issued with it, but no attempts should be made to exceed the maximum tolerated dose.

Reactions to subsequent injections:

Local

Mild reaction: Reduce the dose by one step.

Severe reaction: Reduce the dose by two steps.

Systemic

Mild reaction: Reduce the dose by two steps.

Severe reaction: Treatment should be discontinued.

Except in cases where a severe systemic reaction has occurred, the course may be continued with caution up to the top dose quoted, or to the highest dose tolerated without significant reaction.

† All dosages should be reduced as required for children.

Pharmaceutical precautions SDV must be stored in a refrigerator (2–8°C). It must not be frozen. Vaccine left over from SDV courses containing pollen allergens must not be used the following year.

Vaccine left over from the No. 3 vial of courses which do not contain pollen allergens may be used for maintenance therapy (see Maintenance therapy for vaccines which do not contain pollen allergens).

Legal category POM.

Package quantities Each course of treatment consists of a set of three multidose vials of vaccine in grade concentrations. An instruction leaflet is supplied with each set.

The No. 3 vial is also available for physicians practising maintenance therapy with SDV courses which do not contain pollen allergens (see Dosage and Administration).

Normal delivery time for a complete course or a single vial is about two weeks to allow for individual formulation and sterility testing.

Further information Ordering Procedure: FP10 form (or other prescriptions) should be taken to a chemist who will arrange the supply of the vaccine.

The prescription should be accompanied by the following information:

When available a Skin Test Reaction Chart or a list of the allergens to be included in the vaccine with a note of the patient's sensitivity to each one, or the reference number of a previous course.

Patient's name

Patient's date of birth and/or age

The Bencard Medical Department will be pleased to advise on any aspect of treatment.

VITAVEL* SYRUP

Presentation *Appearance:* Orange coloured syrup.

Active ingredients: One 5 ml spoonful contains:

Vitamin A	4000 units
Vitamin D ₂	300 units
Vitamin B ₁ (Thiamine hydrochloride)	0.8 mg
Vitamin C	16 mg
Glucose	25% w/v

in an orange flavoured sucrose base.

Uses *Principal action:* Vitavel is a multivitamin dietary supplement.

Uses: As a course of vitamin supplementation therapy in premature babies and in infancy, during periods of rapid growth in childhood and adolescence, during illness and convalescence. For adults, during pregnancy and lactation or when tablets cannot be tolerated.

Dosage and administration For oral administration only.

Children and adults: One or two 5 ml spoonfuls daily.

Infants: 2.5 ml to 5 ml in a little water daily. (Syrup B is a suitable diluent.)

Contra-indications, warnings, etc

Contra-indications: Nil.

Side-effects: None reported.

Overdosage: Prolonged ingestion of massive doses of vitamins A and D can lead to hypervitaminosis state.

BENCARD

BENGUÉ'S BALSAM*

Presentation Creamy yellow, soft, greasy ointment: odour of menthol and methyl salicylate. Menthol 20%, methyl salicylate 20% in lanolin base.

Uses Topically as a rubefacient and counter-irritant for the alleviation of rheumatic and nerve pains; as a decongestant by application to the chest or inhalation from hot water in head colds, coughs and laryngo-bronchitis.

Dosage and administration Apply with gentle massage to the affected area.

Contra-indications, warnings, etc Not to be used as an inhalant in children under the age of six years.

Pharmaceutical precautions Store in a cool place. Incompatible with aqueous liquids or emulsions.

Legal category GSL.

Package quantities Tubes of 25 g.

Further information Nil.

Product licence number 0102/5005.

BENGUÉ'S BALSAM SG*

Presentation White, non-greasy cream: odour of menthol and methyl salicylate. Menthol 10%, methyl salicylate 15% in vanishing cream base.

Uses Topically as a rubefacient and counter-irritant for the alleviation of rheumatic and nerve pains; as a decongestant by application to the chest or inhalation from hot water in head colds, coughs and laryngo-bronchitis.

Dosage and administration Apply with gentle massage to the affected area.

Contra-indications, warnings, etc Not to be used as an inhalant in children under the age of six years.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities Tubes of 25 g.

Further information Nil.

Product licence number 0102/5006.

CORTENEMA*

Presentation Off-white, slightly viscous suspension. Each 60 ml unit contains hydrocortisone 100 mg in aqueous isotonic saline.

Uses An adjunct in the treatment of idiopathic specific ulcerative colitis. It is most useful in involving the rectum, sigmoid and descending colon. Rectal steroid therapy brings about prompt and proctological remissions in a significant number of patients, but it does not alter the progressive nature of ulcerative colitis. This form of treatment is not recommended for patients during periods of remission.

Dosage and administration The usual dose is 100 ml of Cortenema Retention Enema daily for the first 7 days, and every second day thereafter. The enema should be given intra-rectally in the evening before bedtime. The patient should be made to retain the medication for at least 1 hour, preferably all night. This may be facilitated by sedation and/or antidiarrhoeal medication. If proctological improvement fails to occur after three weeks, this form of treatment should be discontinued.

Instruct the patient to lie on his left side for instillation. The bottle must be shaken well to ensure homogeneity. Expose the lubricated tip of the protective sheath, grasping the neck where it is most rigid. Carefully insert the tip into the rectum in the distal sacrum. Slowly express the contents by compressing the container. After instillation, the patient should lie on his left side for at least thirty minutes to allow distribution of the hydrocortisone throughout the descending colon and rectum. In order to reach the more distant segments of the colon, Cortenema may be given with isotonic saline, from 100 ml to 300 ml, administered by intra-rectal drip.

Contra-indications, warnings, etc Cortenema is not suitable in cases where several complications are present, including obstruction, abscesses, fistulae and sinus tracts, are present. Patients with ulcerative disease are unsuitable because of perforation of the bowel wall.

Pharmaceutical precautions Store in a cool place. Protect the enemas from light.

Legal category POM.

Package quantities Cartons of 7 x 60 ml units.

Further information The flexible disposable container with lubricated applicator nozzle is designed for ease of self-administration for out-patient use. To obtain optimum distribution of the enema it is important that patients should follow the illustrated directions enclosed in each pack.

Product licence number 0102/5010.

DERBAC* LIQUID WITH MALATHION

Presentation A white, creamy liquid containing malathion 0.5% w/w.

Uses Eradication of head lice and pubic lice and their eggs. Treatment of scabies.

Dosage and administration *Adults and children:*

1. Treatment of head lice.
 - a) Apply Derbac Liquid to the roots of the hair and scalp, paying special attention to the partings, back of the neck, fringes and around ears.
 - b) Leave the hair to dry naturally and wash in ordinary shampoo the next day.
 - c) After shampoo wash, remove dead eggs (nits) with the Derbac metal comb *while the hair is wet*.
2. Treatment of pubic lice.
 - a) Apply freely to all parts of the hair in the affected areas, paying special attention to the roots.
 - c) Leave for at least one hour and then remove by washing with a bland shampoo or soap. If more convenient, Derbac Liquid can be left on overnight.
3. Treatment of scabies.
 - a) Take a fairly prolonged soap and water bath, rubbing the principal areas of involvement with a brush or wash-cloth.
 - c) Apply Derbac Liquid to the entire skin surface, excepting the head. This is best done by someone other than the patient to avoid missing some areas.
 - c) Do not bathe for 24 hours. Put on fresh clothing. No special sterilisation of clothing is necessary; ordinary laundering or dry cleaning and hot iron pressing are sufficient.
 - d) The itching may not subside immediately; calamine lotion may be applied if necessary.

Not to be used in children under the age of six months except under medical supervision.

Contra-indications, warnings, etc There are no known contra-indications to the use of Derbac Liquid. As with all medicated products, keep out of the eyes, as some irritation may occur.

It is advisable that clinic workers in regular contact with this product should wear rubber gloves when carrying out treatment.

Derbac Liquid is for external use only and should be kept out of the reach of children. If Derbac Liquid is inadvertently swallowed, a doctor or casualty department should be contacted at once.

Continued prolonged treatment with Derbac Liquid should be avoided. It should not be used more than once a week for three weeks at a time.

Treatment of overdosage: It is most unlikely that a toxic dose of malathion will be ingested. Treatment consists of gastric lavage, assisted respiration and, if necessary, administration of atropine.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Bottles of 50 ml and 155 ml.

Further information For less severe infestations use Derbac Shampoo or Derbac Soap.

Product licence number 0102/0005.

DERBAC* SHAMPOO WITH CARBARYL

Presentation A yellow opalescent liquid containing carbaryl 0.5% w/w in a shampoo base.

Uses Treatment of head lice (pediculosis).

Dosage and administration *Adults and children:* For less severe infestations wash the hair thoroughly with Derbac Shampoo, rinse with clean water, apply a further quantity of shampoo and work into a rich lather. Allow to remain on the head for five minutes. Rinse with clean water and remove nits with the Derbac Comb.

Not to be used in children under the age of six months except under medical supervision.

Contra-indications, warnings, etc There are no known contra-indications to the use of Derbac Shampoo. As with all medicated shampoo products, keep out of the eyes, as some irritation may occur.

It is advisable that clinic workers in regular contact with this product should wear rubber gloves when carrying out treatment.

Derbac Shampoo is for external use only and should be kept out of the reach of children. If Derbac Shampoo is inadvertently swallowed, a doctor or casualty department should be contacted at once.

Continued prolonged treatment with Derbac Shampoo should be avoided. It should not be used more than once a week for three weeks at a time.

Treatment of overdosage: It is most unlikely that a toxic dose of carbaryl will be ingested. Treatment consists of gastric lavage, assisted respiration and, if necessary, administration of atropine.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Bottles of 50 ml.

Further information For severe cases of infestation, Derbac Liquid with Malathion should be used.

Product licence number 0102/0006.

DERBAC* SOAP

Presentation An ivory-white soap tablet containing γ -benzene hexachloride 1% w/w and cresol 0.779% w/w.

Uses As an adjunct to therapy with Derbac Liquid and Derbac Shampoo and for scalp hygiene.

Dosage and administration *Adults and children:*

1. For severe cases of infestation with head lice use Derbac Liquid. Apply freely to all parts of the hair, paying special attention to the roots and the scalp. Leave to dry naturally, then remove by washing with a bland shampoo or Derbac Soap. Remove nits using the Derbac Comb.
2. For less severe infestations wash the hair thoroughly with Derbac Soap, rinse with clean water, apply a further quantity of cleanser and work into a rich lather. Allow to remain on the head for 15 minutes, rinse with clean water and remove nits with the Derbac Comb.

Contra-indications, warnings, etc There are no known contra-indications to the use of Derbac Soap. As with all medicated products, keep out of the eyes, as some irritation may occur.

It is advisable that clinic workers in regular contact with this product should wear rubber gloves when carrying out treatment.

Derbac Soap is intended for external use only and should be kept out of the reach of children.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Tablets of 74 g (2½ oz).

Further information Nil.

Product licence number 0102/5900.

NESTOSYL* OINTMENT

Presentation Buff-coloured, greasy ointment; odourless. Benzocaine 2%, butyl aminobenzoate 2%, resorcin 2%, zinc oxide 10%, hexachlorophane 0.1%.

Uses Topically for the relief of local pain and irritation in lacerated skin conditions; also in haemorrhoids and anal pruritus.

Dosage and administration Apply and cover if necessary with a light dressing.

Contra-indications, warnings, etc Idiosyncrasy to aminobenzoates. Not to be used for babies.

Pharmaceutical precautions Store in a cool place. Replace cap after use. Incompatible with aqueous liquids and emulsions.

Legal category P.

Package quantities Tubes of 30 g supplied with rectal nozzles.

Further information Nil.

Product licence number 0102/5015.

OPOBYL*

Presentation Spherical pills approx. 7.5 mm diameter, coated deep blue with name of product printed in black. Desiccated liver 50 mg, sodium tauroglycocholate 50 mg, aqueous extract of boldo 10 mg, podophyllin 2 mg, alcoholic extract of euonymus 2 mg, aloes 20 mg per pill.

Uses Hepatic insufficiency. Biliary stasis. Habitual constipation caused by intestinal sluggishness.

Dosage and administration *Adults:* One or two pills before or after meals.

Not recommended for children.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tubes of 50 pills.

Further information Nil.

Product licence number 0102/5017.

PYOREX* MEDICATED TOOTHPASTE

Presentation Homogeneous pink paste, odour a taste of aniseed and peppermint. Acetarsol lithic equivalent to acetarsol 0.45%, aminacrine hydrochlor 0.006%, sodium ricinoleate 0.76%.

Uses Topically, for cleansing the teeth and prevention and treatment of pyorrhoea, stomatitis & gingivitis.

Dosage and administration Apply to gums tw daily.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Tubes of 50 g.

Further information Nil.

Product licence number 0102/5021.

RHINAMID*

Presentation Clear, colourless aqueous liquid; od of rosemary; bitter taste. Sulphanilamide 0.4%, ephedrine hydrochloride 1.0%, butacaine sulphate 0.026%.

Uses As an antiseptic and nasal decongestant, inflammatory and congestive affections of rhinopharynx.

Dosage and administration Two to three drops i each nostril two to five times daily.

Contra-indications, warnings, etc Sulphanilamide sensitivities. The prolonged use of vasoconstrictor: not recommended in chronic rhinitis.

Pharmaceutical precautions To avoid crystallisation do not store in a very cold place.

Legal category POM.

Package quantities Dropper bottles of 30 ml.

Further information Nil.

Product licence number 0102/5022.

ARVIN*

Presentation A sterile, clear, colourless aqueous solution of anicrod for intravenous and subcutaneous injection. Each 1 ml contains 70 International units put up in isotonic saline. pH is 6.8, phosphate content approximately 0.0025 M, chlorbutol approximately 0.005% w/v.

The International unit is defined as the specific biological activity contained in 0.307 mg of the International Standard for anicrod.

Uses For the prevention of deep venous thrombosis after surgical repair of fractured neck of femur, and of re-thrombosis after thrombolytic therapy or vascular surgery.

For the treatment of established deep vein thrombosis, central retinal and branch vein thrombosis, priapism, pulmonary hypertension of embolic origin, embolism after insertion of prosthetic cardiac valves.

Arvin acts enzymatically on the fibrinogen molecule to form friable, unstable non cross-linked particles 1–2 μ m long, easily digested by plasmin and removed by reticulo-endothelial phagocytosis and/or fibrinolysis. Other clotting factors are not affected and unlike thrombin Arvin does not directly activate Factor XIII or plasminogen, does not degrade pre-formed fully cross-linked thrombin fibrin or produce platelet aggregation. It does not cause the release of ADP, ATP, potassium or serotonin from platelets. Platelet survival and counts are normal.

When the fate of Arvin labelled with 125 I is followed, half the radioactivity disappears from the plasma in three to five hours, and at about four days 10% remains.

The blood viscosity in patients receiving Arvin is progressively reduced by 30–40% of the pre-treatment levels.

Dosage and administration *Induction Dose i.v.*

Route: The first dose of Arvin must be given slowly so that the physiological methods of dealing with the particulate fibrin are not overloaded.

2–3 units/kg body weight in 50–500 ml Sodium Chloride Injection BP by intravenous drip during a period of 4 to 12 hours, usually six to eight hours, according to the situation. Dextran must not be used.

There is no information concerning the safety of reducing the induction dose duration to less than four hours in man.

Maintenance Doses i.v. Route: 2 units/kg body weight in 10–50 ml Sodium Chloride Injection BP by intravenous injections at 12 hour intervals, given slowly, taking about five minutes over each injection. Alternatively, the maintenance dose can be given by slow drip or pump infusion.

It is considered that the ideal period of treatment in patients with conditions such as deep vein thrombosis, central retinal vein thrombosis, etc. is of the order of seven days. Some patients have been successfully treated with Arvin for periods of up to 28 days.

Subcutaneous dosage for the prophylaxis of DVT in patients undergoing surgery for fractured neck of femur: Four ampoules as a single s.c. injection immediately after surgery then one ampoule daily for the next four post-operative days.

Control methods and recommended aims: There are three usual methods of estimating the effect of Arvin on the plasma fibrinogen. The reference and aims are given below and copies of the methods are available on application to the Company.

The general aim is to ensure that fibrinogen levels are maintained at or below 50 mg/100 ml and the clot quality observation test is adequate for this purpose.

1. **Method:** Clot quality observation test, Reid, H. A., Chan, K. E., and Thean, P. C. (1963): *Lancet*, i, 621.

Aim: Grade 4 ('Mini-clot'). Diameter of clot = 2 to 3 mm.

2. **Method:** Gravimetric method modification by Pitney, W. R., of Ratnoff, O. D., and Menzie, C. (1951): *J. Lab. Clin. Med.*, 37, 316.

Aim: Plasma fibrinogen $\leq$ 50 mg %.

3. **Method:** Titre in saline and protamine sulphate. Modification by Royal Postgraduate Medical School, London, of Sharp, A. A., Warren, B. A., Paxton, A. M., and Allington, M. J. (1968): *Lancet*, i, 493.

Aim: Saline	Protamine
0 to $\frac{1}{2}$	$\frac{1}{2}$ to $\frac{1}{4}$

Contra-indications, warnings, etc

Contra-indications: Severe infections and diffuse intravascular coagulation – there is some evidence that the Arvin effect may be dangerous in septicæmic states with or without evidence of diffuse intravascular coagulation.

Plasma expanders – Artificial plasma expanders (e.g. Dextran) may cause severe bleeding in defibrinated patients and should not be administered during or within 10 days of Arvin therapy.

Pregnancy – Arvin was not found to be teratogenic in animal studies, but some foetal deaths occurred as a result of placental haemorrhages in animals given high doses. Arvin should not, therefore, be used during pregnancy. The defibrination mechanism of Arvin might be expected on theoretical grounds to interfere with the normal implantation of the fertilised egg.

Gastro-intestinal pathology – the presence of lesions liable to bleed, such as peptic ulcer, ulcerative colitis, etc.

Ulcero-genic drugs – similarly, patients on drug regimes known to cause gastro-intestinal bleeding should not be given Arvin.

Haematological defects – underlying defects interfering with haemostasis, such as a platelet count $< 100,000/\text{cu mm}$. are also contra-indications.

Reticulo-endothelial and lytic systems – drugs that block the reticulo-endothelial system (e.g. dextrans), or the physiological lytic system (e.g. EACA), should not be used concurrently with Arvin.

Side-effects: Haemorrhage – if necessary, the effects of Arvin may be rapidly reversed by the specific antidote described below. In most instances this is unnecessary – stopping Arvin therapy will allow the fibrinogen to return to haemostatic levels within a few hours.

Whole blood, plasma or albumin may be given as needed, but artificial plasma expanders must not be used until plasma fibrinogen levels have returned to normal.

Minor bleeding and oozing – these are simply dealt with by pressure.

Skin rash – reactions are rare and have responded to antihistamine.

Precautions: Induction Dose – the first dose of Arvin must not be given faster than over a period of four hours. Six to eight hours is the ideal duration.

Pretreatment investigations – it is recommended that a blood film, platelet count and fibrinogen estimation should be made before treatment.

Daily control – it is considered necessary to repeat the fibrinogen estimation each day when Arvin is given by the intravenous route.

Arvin should not be given in association with artificial plasma expanders such as Dextran.

Cardiovascular disease – the following cardiovascular conditions may be complicated by defibrination: malignant hypertension, acute pericarditis; sub-acute bacterial endocarditis, retinopathy, grade 3 or worse; diabetic retinopathy; resting diastolic pressure > 120 mm Hg.

Other conditions – similarly, defibrination may cause bleeding in uraemia > 100 mg%; renal colic with calculus; cerebrovascular accidents; history of neurosurgery.

Circulatory insufficiency – If the Induction Dose is given rapidly there may be an initial rise in blood viscosity. Where there is circulatory insufficiency the period of administration should be lengthened to 12 hours.

Coronary thrombosis – in view of some evidence of delay in wound healing in experimental animals, it is considered at the present time that Arvin should not be used in coronary thrombosis, until further data on safety are available.

Migraine – a few patients with a history of migraine have experienced headaches after Arvin injections. Maintenance doses should be given very slowly to such patients.

Minor surgery – it is possible to carry out minor surgery (e.g. opening an abscess) while the patient is on Arvin, but each case must be carefully judged for risk of bleeding.

Major surgery – usually intravenous Arvin is not recommended before, during or within 48 hours of major surgery. An exception is to prevent rethrombosis after vascular surgery when the risk of bleeding does exist. Arvin should be given immediately post-operatively.

Intramuscular route – this is not recommended as an alternative to intravenous administration owing to the risk of inducing antibody formation. Subcutaneous Arvin has shown good control of fibrinogen levels and continues to be studied.

ESR – during treatment with Arvin, the erythrocyte sedimentation rate falls to about 1 mm/hour and cannot be used as an index of pathological activity.

Treatment of overdosage: A specific antidote to Arvin has been prepared.

It is filled in 1 ml ampoules and each 1 ml is sufficient to neutralise 70 International units of Arvin *in vivo*.

The need for the antidote has been very rare, but it is recommended that it is always available when Arvin is

used. Antidote should be used in the event of severe haemorrhage, or if major surgery becomes necessary. The following procedure is recommended for the use of the antidote:

1. 1 in 1,000 adrenaline should be available on the giving tray.

2. Give 0.2 ml antidote subcutaneously and observe for an erythematous reaction for half hour.

3. If satisfactory, give 0.8 ml antidote intramuscularly and observe for a nodular reaction for a further half hour.

4. If satisfactory, give 1 ml intravenously.

5. Give 5 g human fibrinogen intravenously (available from the Regional Blood Transfusion Centre). If this is not available, give 1 litre fresh plasma or whole blood.

The whole procedure takes about one hour and the plasma fibrinogen is normal at the end of it.

In emergencies the intramuscular dose may be omitted. It is recommended that the subcutaneous test dose is never omitted. In the case of a reaction after the subcutaneous dose, do not give any more antidote but give fresh plasma or whole blood. If a nodular reaction after the intramuscular dose is observed, it is expected that any serum sickness to follow will be very mild owing to the highly purified state of the globulin.

The above steps are those usually taken when it is considered adequate to return the plasma fibrinogen to normal levels in about one hour. *In the case of life-threatening bleeding, however, when immediate neutralisation of the Arvin effect is essential, the highly purified nature of the antidote allows intravenous injection without the usual trial doses, with a normal supportive corticosteroid/antihistamine regime ready if anaphylactic shock develops. Fibrinogen should also be administered as in paragraph 5 above.*

Pharmaceutical precautions Store under refrigeration (4–10°C). Do not freeze.

Legal category POM.

Package quantities Ampoules 1 ml containing 70 International units per ml. Pack of 4.

Further information *Clinical effects:* The properties of Arvin provide *controlled therapeutic defibrination* to prevent the formation and extension of thrombi and the dissemination of emboli. Despite marked hypocoagulability, spontaneous haemorrhage is rarely observed, although serosanguineous oozing or frank haemorrhage may be seen in incompletely healed operation wounds. Consistent clinical features include the absence of thromboembolic events during treatment, normal menstruation, absence of fibrinogen rebound and a very low incidence of rethrombosis after treatment is stopped. The plasma fibrinogen returns to haemostatic levels within 12 hours and to normal levels usually around the 10th post treatment day, but in a few patients this may be delayed for a further 10 days. Apart from apparently avoiding rebound hypercoagulation, this slow return of fibrinogen allows a smooth change over to oral anticoagulants when necessary. While Arvin does not lyse established thrombi, rapid resolution of secondary oedema has been noted frequently and is believed to result from improved flow in the microcirculation.

Product licence number 0152/0099.

ASILONE®

Presentation *Tablets:* White, square tablets marked 'ASILONE'. Each tablet contains activated dimethicone

270 mg and the equivalent Dried Aluminium Hydroxide BP 500 mg.

Orange Tablets: Orange, square tablets marked 'ASILONE'. Each orange flavoured tablet contains activated dimethicone 270 mg and the equivalent of Dried Aluminium Hydroxide BP 500 mg.

Suspension: White suspension containing in each 5 ml activated dimethicone 135 mg and the equivalent of Dried Aluminium Hydroxide BP 420 mg and Light Magnesium Oxide BP 70 mg.

Gel: Thick white suspension containing in each 5 ml, activated dimethicone 135 mg and the equivalent of Dried Aluminium Hydroxide BP 420 mg and Light Magnesium Oxide BP 70 mg.

Asilone for Infants: White, blackcurrant-flavoured suspension containing in each 5 ml, activated dimethicone 27 mg and the equivalent of Dried Aluminium Hydroxide BP 84 mg and Light Magnesium Oxide BP 14 mg.

Uses Mucosal protective, antifatulent and antacid; dyspepsia, flatulence and abdominal distension; heartburn in pregnancy; heartburn in hiatus hernia; drug-induced gastritis, dietary induced gastritis; symptomatic relief in peptic ulceration.

Asilone for Infants: The treatment of wind pains, 'gripes' and regurgitation in infants over one month of age.

Dosage and administration *Tablets and orange tablets:* 1–2 tablets chewed or sucked before meals and at bedtime. For heartburn they should be sucked slowly.

Suspension & gel: One or two 5 ml spoonfuls before meals and at bedtime.

Asilone for infants: Infants 1–3 months: 2.5 ml 3 to 4 times daily before or during a feed.

3 months and over: one 5 ml spoonful three to four times daily before or during a feed.

In windy colic it may be necessary to continue dosage for 24 hours before relief is achieved. Asilone for Infants may be given at the recommended dosage for several weeks, if that is necessary, but should not be continued for more than 48 hours without medical advice, as symptoms may not be due to intestinal gas. It should not be used in infants under one month of age.

Contra-indications, warnings, etc There are no known contra-indications to Asilone, but it is probably wise to avoid taking preparations containing antacids in the first trimester of pregnancy.

Very rarely, minor disturbances of bowel function have been reported.

Asilone Tablets and Asilone Orange Tablets each contain 1 g sucrose per tablet and are therefore less suitable for diabetic patients than the Suspension and Gel which contain no sugars.

Pharmaceutical precautions No special precautions.

Diluent for Asilone for Infants, Asilone Suspension and Gel: Purified Water BP.

Legal category

Tablets: GSL.

Suspension: GSL.

Gel: P.

Asilone for infants: P.

Orange tablets: P.

Package quantities *Tablets:* Packs of 12 and 100.

Suspension: Bottles of 100 ml, 300 ml and 500 ml.

Gel: Bottles of 300 ml and 500 ml.

Asilone for infants: Bottles of 100 ml.

Orange tablets: packs of 100.

Further information The sodium content of the adult Asilone range is low. Asilone is, therefore, particularly suited to the management of gastro-oesophageal conditions where there is co-existing hypertension, congestive heart failure, hepatic failure and/or renal failure.

Asilone suspension: typical sodium content 0.032 to 0.097 mmol per 10 ml.

Asilone gel: typical sodium content 0.040 to 0.090 mmol per 10 ml.

Orange Tablets 0152/0139

ATENSINE*

Presentation White Diazepam Tablets BP 2 mg, marked 'BERK 2', with single break line.

Yellow Diazepam Tablets BP 5 mg, marked 'BERK 5', with single break line.

Blue Diazepam Tablets BP 10 mg, marked 'BERK 10', with single break line.

Uses Acute and chronic anxiety, tension states and muscle spasm.

Dosage and administration *Acute and chronic anxiety states:* Mild anxiety in ambulant patients 2 mg t.i.d.

Severe anxiety states, 15–30 mg daily in divided doses.

Children: 1–5 mg daily in divided doses.

Insomnia associated with anxiety: 5–30 mg before retiring.

Conditions associated with muscle spasm: Spastic children with minimal brain damage: 2–40 mg daily in divided doses.

Cerebral palsy of adults, particularly associated with athetoid movements: 2–60 mg daily in divided doses.

Upper motor neuron spasticity: 5–60 mg daily in divided doses.

Muscle spasm of varied aetiology, fibrositis, cervical spondylosis: 2–15 mg daily in divided doses.

Premedication for dental operations: One 5 mg tablet the night before the appointment, 5 mg on waking and 5 mg two hours before the appointment.

Atensine should be given to elderly and debilitated patients in doses half those recommended for ordinary adults.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to benzodiazepines.

Acute pulmonary insufficiency.

Acute narrow angle glaucoma.

Use in pregnancy: Not to be taken during pregnancy, especially in the first trimester, unless there are compelling reasons.

Precautions: Chronic pulmonary insufficiency.

In chronic renal or hepatic disease.

In labour. High single doses or repeated low doses have been reported to produce hypotonia, poor sucking and hypothermia in the neonate and irregularities in the foetal heart.

Avoid if possible in lactation.

The concurrent use of other CNS depressant drugs should be avoided.

Warnings and adverse effects: Common adverse effects include drowsiness, sedation, unsteadiness and ataxia.

Performance and alertness may be impaired during the first week of administration. Patients should be warned of the possible hazard when driving or operating machinery. These effects may be potentiated by alcohol.

The elderly and the debilitated are particularly liable to experience these symptoms, together with confusion, especially if organic brain symptoms are present.

Rebound insomnia has been reported following abrupt cessation of treatment.

Abnormal psychological reaction to benzodiazepines have been reported. Rare behavioural adverse effects include paradoxical aggressive outbursts, excitement, confusion, and the uncovering of depression and suicidal tendencies.

Other rare adverse effects including hypotension, gastro-intestinal and visual disturbances, skin rashes, urinary retention, headache, vertigo, changes in libido, blood dyscrasias and jaundice have also been reported.

As with any benzodiazepine, excessive or prolonged use of Atensine may result in the development of psychological dependence with withdrawal symptoms on discontinuation.

Treatment of overdose: Ataxia is usually the most serious symptom. Gastric lavage may be carried out, followed by observation. Very occasionally a respirator may be required but Atensine generally causes few problems in overdose. In children behavioural changes are likely.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category POM.

Package quantities *Tablets 2 mg:* Containers of 50, 250, 1,000 and 5,000.

Tablets 5 mg: Containers of 50, 100, 250, 1,000 and 5,000.

Tablets 10 mg: Containers of 500.

Further information Nil.

Tablets 10 mg 0152/0158.

BERKDOPA*

Presentation *Tablets:* White Levodopa Tablets BP 500 mg, with double break line to permit quartering.

Uses Anti-Parkinsonian agent idiopathic, postencephalitic and arteriosclerotic Parkinsonism.

Dosage and administration It is essential that 'Berkdopa' be administered in quite small doses at the beginning of treatment and built up slowly until satisfactory alleviation of symptoms is obtained. 'Berkdopa' should be given in divided doses immediately after food. The following dosage regimen is only a guide to

treatment, and it should be noted that dosage can be initiated at a lower level, if desired, or increased by increments of up to 1 g every three or four days depending on patient response.

Dosage – a guide to treatment

Week 1: 250 mg daily in divided doses.

Week 2: 500 mg daily in divided doses.

Week 3: 250 mg t.i.d.

Week 4: 500 mg t.i.d.

Week 5: 750 mg t.i.d.

Week 6: 1,000 mg t.i.d.

Week 7: 1,250 mg t.i.d.

Week 8: 1,500 mg t.i.d.

Thereafter increments of 500 mg per day may be given every three or four days until the dosage is built up to a maximum of 8 g 'Berkdopa' per day or until a level is reached where satisfactory alleviation of symptoms is obtained.

The optimum alleviation of symptoms may occur at a lower dose, sometimes even 1 g per day is adequate. The decision as to what dosage level to adopt must be that of the physician.

Treatment for up to six months may be necessary before maximal improvement is achieved. Treatment with anticholinergic agents may be continued.

Contra-indications, warnings, etc Berkdopa is contra-indicated in concomitant administration with monoamine oxidase inhibitors. If the patient is being treated with one of these drugs it must be withdrawn before Berkdopa is administered and a period of 14 days should elapse between the withdrawal and the commencement of Berkdopa therapy.

Berkdopa is contra-indicated in cases of severe psychosis or neuro-psychosis and narrow angle glaucoma (but may be used in wide angle glaucoma provided there is adequate control of intra-ocular pressure). Levodopa may be implicated in activation of a malignant melanoma. Berkdopa should not be used in persons with a history of, or who may suffer from, a malignant melanoma.

Special care should be taken when using Berkdopa in endocrine, renal, hepatic, pulmonary or cardiovascular disease, particularly when there is a history of myocardial infarction, and in patients with peptic ulcer. Care should also be taken when patients have to be treated with sympathomimetic drugs, for example in the treatment of bronchial asthma and with antihypertensive drugs, particularly methyl dopa and ganglion blocking agents.

Periodic evaluation of hepatic, haemopoietic, renal and cardiovascular function is advised.

Pyridoxine (vitamin B₆) which is often in multivitamin preparations blocks the effects of levodopa.

Drugs affecting central amine mechanisms such as Rauwolfia alkaloids (reserpine) phenothiazines, thioxanthenes, butyrophenones and amphetamines should be avoided if possible. If their administration is essential care should be exercised and interactions or unusual side effects should be watched for.

When other drugs are given in conjunction with Berkdopa the patients should be carefully observed for any untoward side-effects.

The established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed for Berkdopa.

Nausea and vomiting may occur, especially if the rate of build-up of dosage is too rapid, or if not taken immediately after food. Anorexia and hypotension may also occur during the initial period of treatment. At higher

doses, involuntary movements, psychiatric disturbances and sometimes cardiac arrhythmia may be seen.

At higher levels of drug dosage, dyskinesias are sometimes induced, such as involuntary facial movements, tongue protrusion and twisting, head nodding and rotation. These may be reduced or abolished by a small reduction of between 0.5–1 g of Berkodopa per day.

Psychiatric disturbances such as mild elation, depression, anxiety, agitation, etc. can be encountered.

Treatment of overdosage: The effects of overdosage are qualitatively similar to the side effects of Berkodopa, but are of greater magnitude. Treatment should include gastric lavage and administration of intravenous fluids. The heart should be monitored for possible dysrhythmias and appropriate treatment instituted if necessary.

Pharmaceutical precautions Store in a cool place, protect from light and moisture.

Legal category POM.

Package quantities *Tablets:* Containers of 100 and 500.

Further information Levodopa is primarily useful in treating the akinesia and rigidity of Parkinsonism. Parkinson tremor is often but not always alleviated. Levodopa will also treat the 'mental akinesia' of Parkinson's disease and will induce a mood elevation and a feeling of well-being. The dysphagia, hypersalivation and dysarthria of Parkinsonism may also be relieved by levodopa.

Tablets 500 mg 0152/5036

BERKFURIN*

Presentation Plain yellow Nitrofurantoin Tablets BP 50 mg and 100 mg. Single break line.

Uses Urinary antibacterial agent. Urinary tract infection.

Dosage and administration The average adult dose is 400 mg daily:

Tablets 50 mg: 2 tablets with each meal and 2 at bedtime with milk.

Tablets 100 mg: 1 tablet with each meal and 1 at bedtime with milk.

Treatment should continue for 14 days and courses should be separated by 4 weeks.

Berkfurin is not recommended for children.

Contra-indications, warnings, etc Severe renal impairment – serum creatinine above 2 mg%, creatinine clearance below 40 ml/minute – anuria, oliguria and uraemia. Previous sensitivity to nitrofurantoin.

Polyneuropathy may occur and impaired renal function increases the risk of this complication because of raised blood levels.

Therefore, where renal function is poor, the dose of 'Berkfurin' should be reduced and the drug should be withdrawn at once if paraesthesia is reported. Similar caution is necessary in cases of diabetes mellitus, anaemia, B-avitaminosis and alcoholism. Severe renal damage is an absolute contra-indication to the use of 'Berkfurin'.

Nausea and vomiting sometimes occur and cease on reducing the dose. Allergic reactions, both generalised and cutaneous, occur occasionally and in these cases

the drug should be withdrawn. Anaemia, both megaloblastic and haemolytic, has occurred after nitrofurantoin therapy and there have been reports of liver damage.

Treatment of overdosage: Vomiting may occur but other serious symptoms are unlikely. Gastric lavage might be beneficial in the first hours after ingestion followed by conservative management.

Pharmaceutical precautions Store in a cool place, protect from light.

Legal category POM.

Package quantities *Tablets 50 mg:* Containers of 100.

Tablets 100 mg: Containers of 100.

Further information Nil.

Tablets 100 mg 0152/5031.

BERKMYCEN*

Presentation *Tablets:* Yellow film-coated Oxytetracycline Tablets BP 250 mg engraved BERK 1C5 on one side.

Capsules: Red/yellow Oxytetracycline Capsules BP 250 mg.

Uses Antibiotic.

Infections caused by oxytetracycline-sensitive organisms. These include acute and chronic bronchitis, pneumonia, urinary tract infections, brucellosis, pertussis, rickettsial fevers and psittacosis.

Dosage and administration *Adults:* 250 mg every six hours. In severe infections dosage may be increased to 250 mg every three hours after an initial loading dose of 1 g.

Contra-indications, warnings, etc 'Berkmycen' should only be given to patients with renal dysfunction or failure if its use is considered essential.

Milk, or antacids containing aluminium, magnesium or calcium, interfere with the absorption of oxytetracycline. If gastric irritation occurs the tablets should be taken with food. As with all tetracyclines, 'Berkmycen' should be used with caution in patients with hepatic or renal dysfunction.

Berkmycen should not be used in late pregnancy or given to children during the period of tooth development, unless it is essential to use a tetracycline because of resistance to other antibiotics.

Like all tetracyclines, 'Berkmycen' may produce gastro-intestinal irritations, giving rise to nausea, abdominal discomfort and diarrhoea. Intestinal overgrowth of resistant organisms (*Candida albicans* in particular) may occur. Drug fever and allergic skin rashes may occur rarely.

Treatment of overdosage: Serious symptoms are unlikely. Gastric lavage might be beneficial in the first hours after ingestion followed by conservative management. Milk will reduce absorption.

Pharmaceutical precautions Incompatible with alkalis and chloramphenicol.

Legal category POM.

Package quantities *Tablets*: Containers of 1,000 and 5,000.

Capsules: Containers of 100.

Further information 'Berkmycen' oxytetracycline is an antimicrobial agent active against most pathogenic bacteria, both Gram-positive and Gram-negative, except for the majority of strains of *Proteus vulgaris* and *Pseudomonas aeruginosa*. *Salmonella* species and *Mycobacterium tuberculosis* show resistance, as do the yeasts and fungi, but 'Berkmycen' is effective against *Actinomyces*, *Entamoeba histolytica*, *Trichomonas vaginalis*, treponemata and some rickettsias and viruses.

BERKOLOL*

Presentation

1. Pink, film-coated, Propranolol Tablets BP 10 mg embossed BERK 121, with breakline on reverse.
2. Pink, film-coated, Propranolol Tablets BP 40 mg embossed BERK 221, with breakline on reverse.
3. Pink, film-coated, Propranolol Tablets BP 80 mg embossed BERK 321, with breakline on reverse.
4. Pink, film-coated, Propranolol Tablets BP 160 mg embossed BERK 421, quadrisected with double breakline on reverse.

Uses Berkolol is a competitive blocker of adrenergic β -receptor sites. It is used in the treatment of hypertension, angina pectoris, cardiac dysrhythmias, tachycardia, anxiety and essential tremor. It may also be used as a prophylactic in migraine, and as adjunctive therapy in thyrotoxicosis.

Dosage and administration Dosage requires individual adjustment. A heart rate of 55/min or less is an indication that dosage should be increased no further.

Adults: Hypertension: Initially, 80 mg twice daily, increased where necessary at weekly intervals. The usual maintenance dosage is 160–320 mg daily. Lower doses may be effective when a diuretic or other antihypertensive drug is given concurrently.

Angina pectoris: Initially, 40 mg twice or thrice daily increased by the same amount at weekly intervals until control is achieved, or the maximum daily dose of 480 mg is reached.

Anxiety, migraine, essential tremor: 40 mg twice or thrice daily, increased at weekly intervals if needed to a daily total of 80–160 mg.

Dysrhythmias, anxiety tachycardia, hypertrophic obstructive cardiomyopathy, thyrotoxicosis: 10–40 mg three or four times daily.

Children: Dysrhythmias, thyrotoxicosis: The minimum effective dosage, based on 0.25–0.5 mg/kg body weight, three or four times daily.

Migraine: Children under the age of 12 may be given 20 mg two or three times daily. Older children may be given adult dosage.

Contra-indications, warnings, etc

Contra-indications: Second or third degree heart block; History of bronchospasm; Prolonged fasting; Metabolic acidosis.

Precautions: Although there is no evidence that pro-

pranolol is teratogenic, Berkolol should not be used in pregnancy unless it is considered essential.

Berkolol should be used with great caution in patients with heart failure, unless that is due to thyrotoxicosis alone. Concomitant therapy with digitalis and diuretics is usually desirable in these cases.

Berkolol should be withdrawn 24 hours before elective surgery, as it may interfere with response to stress. If this cannot be done, 1–2 mg atropine should be given intravenously before anaesthesia commences and anaesthetics such as ether, chloroform, cyclopropane and trichloroethylene, which may cause myocardial depression, should not be used.

Warnings and adverse reactions: Treatment with beta-blocking agents must not be stopped suddenly. If it is necessary to withdraw Berkolol, this should be done gradually, or another beta-blocker should be substituted.

Bradycardia and hypotension are usually a sign of overdosage, but may rarely be due to intolerance of the drug. In the latter case Berkolol should be withdrawn and, if necessary, the patient should be treated as for overdosage. Heart block and congestive heart failure have been reported.

Dry eyes and skin rash have been reported during treatment with β -adrenergic blocking agents. If these symptoms are not attributable to some other cause, Berkolol should be withdrawn.

Berkolol may cause or precipitate Raynaud's phenomenon, intermittent claudication or peripheral arterial insufficiency. Bronchospasm may occur, particularly in patients with a history of asthma or hay fever.

There have been rare reports of blood dyscrasias during treatment with propranolol.

Minor side-effects include cold extremities, nausea, vomiting diarrhoea, fatigue or insomnia. These are usually transient and are less common if the drug is introduced gradually.

Treatment of overdosage: The clinical features can include bradycardia, severe hypotension, bronchospasm, hypoglycaemia, delirium and unconsciousness. Initially isoprenaline should be infused, and if marked bradycardia is present atropine should be given intravenously (0.6–3 mg; 50 mcg/kg in children): if the response is limited, glucagon therapy must be instituted (50–150 mcg/kg intravenously over one minute followed by 1–5 mg/hour infused). Bronchospasm may be treated by nebulized salbutamol or intravenous aminophylline or salbutamol.

Pharmaceutical precautions Protect from light.

BERKOZIDE*

Presentation Plain white Bendrofluazide Tablets BP 2.5 mg and 5 mg. The 5 mg tablets have a single break line.

Uses Diuretic. Oedema, cardiac failure, inhibition of lactation, hypertension.

Dosage and administration In cardiac failure, 5–10 mg daily or on alternate days, a usual maintenance dosage being 5–10 mg on three days per week. For premenstrual oedema, 'Berkozide' may be given 5 mg daily for three to four days before menstruation. For inhibition of lactation 5 mg in the morning and 5 mg at noon for five days is usually adequate. In hypertension the dosage should be 2.5–5 mg daily. Bendrofluazide potentiates other antihypertensive agents, the dosage of which should be reduced and then adjusted as necessary.

Berkozide is not recommended for children.

Contra-indications, warnings, etc 'Berkozide' is contra-indicated in severe renal insufficiency and hypercalcaemia and should be used with caution in patients with renal or hepatic disorders. It may precipitate hepatic coma in advanced cirrhosis.

Potassium supplements should be given (preferably on non-diuretic days) when the dosage of 'Berkozide' is high or when diet is inadequate. It may be necessary to reduce the dosage of digitalis if this is given concurrently.

Toxic effects such as nausea, allergy, skin rashes or blood dyscrasias are rare. Hypokalaemia may develop with long use of 'Berkozide', but this risk is reduced by administration on alternate days. Like other thiazides, bendrofluazide may provoke hyperglycaemia and glycosuria in diabetic patients and may precipitate latent diabetes mellitus. It may also precipitate acute attacks of gout. Breast feeding should be avoided since thiazide diuretics are secreted in mother's milk.

Treatment of overdosage: Replace fluids with saline while monitoring plasma sodium and potassium. Potassium replacement may be required.

Pharmaceutical precautions No special precautions.

Legal category POM.

Package quantities *Tablets 2.5 mg:* Containers of 100 and 1,000.

Tablets 5 mg: Containers of 100 and 1,000.

Further information Bendrofluazide is an oral diuretic of the thiazide group which inhibits proximal tubular resorption of sodium chloride.

Tablets 5 mg 0152/5084.

CAPLENAL®

Presentation

100 mg tablets: white biconvex tablets containing 100 mg of Allopurinol, engraved BERK 1 K1 on one side with a break-line on the reverse.

300 mg tablets: white biconvex tablets containing 300 mg of Allopurinol, engraved BERK 2 K1 on one side with a break-line on the reverse.

Uses *Gout:* Primary hyperuricaemia.

Secondary hyperuricaemia: Prophylaxis of uric acid and calcium oxalate stones.

Dosage and administration *Adults:* The initial dose is 100–200 mg. The maintenance dose is 200–600 mg/daily. Maximum single dose 300 mg. It has rarely been found necessary to exceed 900 mg per day. The dose should be adjusted by monitoring serum uric

acid and/or urinary uric acid levels at appropriate intervals until the desired effect is attained, which may take one to three weeks.

Children: 10–20 mg/kg body weight/day. Use in children is mainly indicated in malignant conditions, especially leukaemia and certain enzyme disorders, for example Lesch-Nyhan syndrome.

Initiation of therapy: In the early stages of treatment with allopurinol, as with the uricosuric agents, an acute attack of gouty arthritis may be precipitated. Therefore it is advisable to give a prophylactic dose of a suitable anti-inflammatory agent or colchicine (0.5 mg three times a day) for at least one month.

Use with uricosurics: As allopurinol does not interfere with the action of uricosuric agents, they may be given concurrently. When changing from uricosuric therapy to allopurinol 1–3 weeks overlap of treatments is recommended to ensure a continuous hypouricaemic effect.

Use in neoplasia: When giving allopurinol to prevent uric acid nephropathy in neoplastic conditions, it is advisable to start treatment with allopurinol before cytotoxic therapy.

Dose recommendations in impaired renal function: Since allopurinol and its metabolites are excreted via the kidney, impairment of renal function may lead to retention of the drug and its metabolites with consequent prolongation of action. Thus, the amount and frequency of the dosage may require reduction as indicated by monitoring serum uric acid levels. The following schedule is provided for guidance in adults.

If creatinine clearance exceeds 20 ml/minute – give standard dose.

If creatinine clearance is between 10 and 20 ml/minute – give 100–200 mg/day.

If creatinine clearance is between 2 and 10 ml/minute – give 100 mg/day or at longer intervals.

Dose recommendations in renal dialysis: Allopurinol and its metabolites are removed by renal dialysis. If frequent dialysis is required an alternative schedule of 300–400 mg allopurinol after each dialysis with none in the interim should be considered.

Contra-indications, warnings, etc

Contra-indications: Acute gout. Known intolerance of allopurinol.

Precautions: Treatment should not be started during or immediately after an acute attack of gout. When 6-mercaptopurine or azathioprine is given concurrently with allopurinol, only one quarter of the usual dose of those drugs should be given because inhibition of xanthine oxidase will prolong their activity. There is no unequivocal evidence that allopurinol potentiates the activity of other cytotoxic drugs. If allopurinol is given concomitantly with chlorpropamide when renal function is poor, there may be an increased risk of prolonged hypoglycaemia activity.

The dosage of allopurinol should be reduced in patients with renal or hepatic diseases.

There is no evidence that allopurinol taken orally causes foetal abnormalities. However, as with all drugs, due caution should be exercised in pregnancy.

Warnings and adverse effects: Adverse reactions in association with allopurinol are usually rare and mostly of a minor nature. The incidence is higher in the presence of renal and/or hepatic disorders. The possible potentiation of anticoagulant action should be borne in mind when a patient on anticoagulants is given allopurinol.

Skin reactions are the most common reactions and may occur at any time during treatment. They may be pruritic, maculopapular, sometimes scaly or purpuric and rarely exfoliative. Allopurinol should be withdrawn immediately should such reactions occur. After recovery from mild reactions allopurinol may, if desired, be reintroduced at a low dose (e.g. 50 mg/day) which may be gradually increased. If the rash recurs, allopurinol should be permanently withdrawn.

Exfoliative skin reactions associated with other signs of hypersensitivity including fever, lymphadenopathy, arthralgia and eosinophilia occur rarely. If they do occur, it may be at any time during treatment. Allopurinol should then be withdrawn immediately and permanently. Corticosteroids may be beneficial in overcoming such reactions. Patients manifesting generalised hypersensitivity reactions usually have pre-existing renal and/or hepatic disorders.

Nausea and vomiting have been reported. This reaction is not a significant problem and can be avoided by taking allopurinol after meals.

There have been occasional reports of transient reduction in the numbers of circulating formed elements in the blood, usually in association with pre-existing renal and/or hepatic disorders. The clinical significance has yet to be demonstrated.

Exacerbation of acute gouty attacks may occur in the early stages of hypouricaemic therapy. In those conditions where the body's miscible urate pool is greatly increased (e.g. malignant diseases and its treatment: Lesch-Nyhan syndrome), the rise in xanthine concentration resulting from the action of allopurinol may lead to tissue deposition of xanthine. Adequate hydration will reduce the risk of xanthine deposition in the kidney and fluid intake should ensure adequate urinary output. Xanthine crystals have been seen in muscle tissue of patients receiving allopurinol but this appears to have no clinical significance.

The following complaints have been reported occasionally, but do not appear to have a clear cause and effect relationship with allopurinol: fever, general malaise, headache, vertigo, somnolence, taste perversion, hepatic necrosis, granulomatous hepatitis, abnormal liver function tests, hyperlipaemia, visual disorder, cataracts, macular changes, neuropathy, impotence, diabetes mellitus, furunculosis, alopecia, hypertension, haematuria, oedema.

Treatment of overdose: No reports of overdose or acute intoxication with Caplenal are available.

Pharmaceutical precautions Store below 25°C in a dry place.

Legal category POM.

CEPLAC

Presentation Rose coloured tablets engraved CEPLAC on one face and plain on the reverse face. Each tablet contains 6 mg erythrocine.

Uses As an aid to the efficient teaching of oral hygiene.

Dosage and administration *Adults and children:* The patient should be given a Ceplac Tablet in the surgery. This will at once demonstrate the shortcomings of his current oral hygiene techniques and make it easier to gain his co-operation.

When he has been shown the correct method of brushing his teeth, he should be sent home with a supply of Ceplac Tablets and instructions on how to use them. Ceplac will play a central role in helping him to acquire the habit of regular and correct tooth brushing.

Initially, at least once a day, the patient should crush one Ceplac Tablet between his teeth before cleaning them, and distribute saliva to all tooth and gum surfaces with the aid of the tongue for at least half a minute. He should then spit out into a bowl of running water, and rinse his mouth once or twice with water.

He should then brush his teeth in the way he has been shown until all red stain has been removed.

Once a sound brushing technique has been established the patient can use Ceplac once or twice a week after brushing, as a check on continuing proficiency.

In the same way, patients should be given Ceplac on each successive visit to the surgery, to assess their progress.

Contra-indications, warnings, etc There are no known contra-indications or adverse reactions.

Treatment of overdose: Gastric lavage.

Pharmaceutical precautions No special precautions.

Legal category GSL.

Package quantities Packs of 12 and 1,000 tablets.

Further information Ceplac stains bacterial plaque and food debris a brilliant red. The stain is non-persistent and is easily removed from lips or clothing with soap and water.

Product licence number 0152/5032.

CREMALGIN®

Presentation Pink balm containing methyl nicotinate 1.0% w/w histamine dihydrochloride 0.1% w/w capsin 0.1% w/w glycol salicylate 10.0% w/w.

Uses Rubefacient balm. In the treatment of rheumatism sciatica lumbago, fibrositis and muscular stiffness.

Dosage and administration Two or three times daily or as required. Place a sufficient quantity on the skin over the affected area and massage gently and smooth the cream through the skin.

Contra-indications, warnings, etc Cremalgin is contra-indicated in those patients with salicylate hypersensitivity. Erythematous reactions may occur in sensitive patients.

Pharmaceutical precautions No special precautions.

Legal category GSL.

Package quantities Tubes of 25 g and 50 g.

Further information Nil.

Product licence number 0152/5019.

DOMICAL®

Presentation Round film-coated bi-convex Amitriptyline Tablets BP marked 'D': 10 mg tablets are blue, 25 mg are orange and 50 mg are red-brown.

Uses Amitriptyline is an antidepressant of the tricyclic group.

It is indicated by symptoms of a depressive illness especially when sedation is required.

Dosage and administration *Adults:* Initially 75 mg/day in divided doses or as a single dose at night, increasing to 200 mg/day according to clinical response. Maintenance dose is 50–100 mg at night.

Elderly or adolescent patients: 10–50 mg daily initially (see 'Precautions').

Children: Domical is not recommended for children under 12 years of age.

Contra-indications, warnings, etc

Contra indications: History of myocardial infarction, arrhythmias, particularly heart block of any degree, congestive cardiac failure, coronary artery insufficiency.

Receipt of monoamine oxidase inhibitors within the last two weeks.

Mania. Severe liver disease. Hypersensitivity to any tricyclic antidepressant. Breast feeding.

Precautions: Safety in pregnancy and lactation has not been established. Do not use during pregnancy nor in nursing mothers unless there are compelling reasons.

The elderly or debilitated are particularly liable to experience toxic effects, especially agitation, confusion and postural hypotension. The initial dose should be increased with great caution under close supervision. Half the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

All patients with severe depression should be closely supervised, particularly during the early stages of therapy when partial response may increase the risk of suicide.

Domical should be used with great caution in patients with a history of narrow angle glaucoma, urinary retention, epilepsy or recent convulsions, hepatic insufficiency, hyperthyroidism, cardiovascular disorders or blood dyscrasias, or symptoms suggestive of prostatic hypertrophy.

Tricyclic antidepressants potentiate the central nervous depressant action of alcohol.

Anaesthetics given during tri/tetracyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that a patient is being so treated.

Drug interactions: In patients who have been treated previously with monoamine oxidase inhibitors, at least two weeks should elapse before treatment with Domical is started, with great caution, commencing with low dosage and slow increments.

Amitriptyline may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly lonidine. It is advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Amitriptyline should not be given with sympathomimetic agents such as ephedrine, isoprenaline, norrenaline, phenylephrine and phenylpropanolamine, or with ethchlorvynol.

The antidepressant action of Domical may be decreased by barbiturates and increased by methylenediamine.

The dose of thyroid hormone medication may need to be reduced if amitriptyline is given concurrently.

Warnings and adverse reactions: As improvement may not occur during the first month of therapy, patients should be closely monitored during this period.

Cardiac arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdosage. They may also occur in patients with pre-existing heart disease taking normal dosage.

Confusion may occur at high doses or in elderly patients, requiring reduction of dosage.

Drowsiness is not uncommon in the early stages of treatment, and patients should be warned not to drive or operate machinery until it has been established that their alertness is not impaired.

The following adverse effects, although not necessarily all reported with amitriptyline, have occurred with tricyclic antidepressants:

Atropine-like side-effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition are common early in treatment, but usually lessen.

Other common adverse effects include nausea, sweating, postural hypotension, dizziness, tremor and rashes. Interference with sexual function may occur.

Serious adverse effects are rare. These include bone marrow depression, agranulocytosis, cholestatic jaundice, hypomania, convulsions and peripheral neuropathy.

Withdrawal symptoms which may occur on abrupt cessation of therapy include insomnia, irritability and excessive perspiration. There have also been reports of withdrawal symptoms in neonates whose mothers received tricyclic antidepressants during the third trimester of pregnancy.

Psychotic manifestations, including mania and paranoid delusions may be exacerbated during treatment with tricyclic antidepressants.

Treatment of overdosage: The major symptoms are likely to be coma and respiratory depression. Primary therapy must be aimed at correction of hypoxia, acidosis and electrolyte imbalance. Gastric lavage should be performed and the ECG monitored. If convulsions occur they may be treated with diazepam. Serious dysrhythmias are rare and DC conversion may be preferable to anticholinesterase agents, which can exacerbate convulsions.

Pharmaceutical precautions No special precautions.

Legal category POM.

DOPAMET®

Presentation Yellow film-coated Methyldopa Tablets BP. 125 mg (marked 'BERK 1C3'). 250 mg (marked 'BERK 2C3'). 500 mg (marked 'BERK 3C3').

Uses Hypertension.

Dosage and administration *Initiating therapy:*

Adults: 250 mg twice a day for two days, increased at intervals of not less than two days by an additional 250–500 mg daily until satisfactory control is achieved. This normally follows within 12–24 hours of reaching the effective dose for the individual patient, which is generally in the range of 500–2,000 mg daily. It is seldom necessary to exceed 3,000 mg daily and, because methyldopa is largely excreted by the kidneys, patients with impaired renal function may respond to comparatively low doses.

The requirement of 'Dopamet' may be reduced by giving a thiazide diuretic concurrently; downward adjustments of dosage should likewise be made at intervals of not less than 48 hours.

In the few cases where tolerance develops, effective control can frequently be restored by increasing the dosage of 'Dopamet' or by adding a diuretic to the regimen.

When patients are on other hypotensive agents and it is desired to change them over to 'Dopamet', drug interactions must be carefully watched for.

Reserpine and other Rauwolfia alkaloids, hydralazine and mebutamate when used alone or in any combination should be discontinued before treatment with 'Dopamet' is started.

Ganglion blocking agents and adrenergic blocking agents used alone or in combination should be withdrawn cautiously and progressively. During the first week of transfer the dosage of blocking agent should be reduced by a half and 'Dopamet' added at a dosage of 250 mg twice a day. The blocking agent is then reduced still further and the dosage of 'Dopamet' adjusted upwards by 250–500 mg stages at two- to seven-day intervals to maintain optimal control of the blood pressure.

Monoamine oxidase inhibitors should be discontinued before treatment with 'Dopamet' commences. It should then be used cautiously in case of delayed excretion of the monoamine oxidase inhibitors.

Contra-indications, warnings, etc Dopamet should not be given in cases of active liver disease, such as acute hepatitis and active cirrhosis, and in patients known to be sensitive to methyldopa. Dopamet is not recommended where phaeochromocytoma is suspected, since methyldopa fluoresces at the same wavelengths as catecholamines in urine samples; spuriously high concentrations of urinary catecholamines may be reported and this will interfere in the diagnosis of phaeochromocytoma. Dopamet should not be used with reserpine, other Rauwolfia alkaloids, hydralazine, mebutamate and monoamine oxidase inhibitors. When methyldopa is used with other antihypertensive agents, potentiation of antihypertensive action may occur. The progress of patients should be carefully followed to detect side reactions or manifestations of drug idiosyncrasy. Patients may require reduced doses of anaesthetics when on methyldopa. If hypotension does occur during anaesthesia, it can usually be controlled by vasopressors. Since experience of methyldopa in pregnancy is still limited, Dopamet is not currently recommended for pregnant women or for nursing mothers, but in serious cases the benefits of the drug might be weighed against any potential risk.

Sedation is the most frequent side-effect and may occur even at the starting dose level. It usually wears off after an effective maintenance dosage has been estab-

lished. Depression may occur and corrective treatment with tricyclic antidepressants may antagonise the therapeutic effect of Dopamet. Other minor side-effects are headache and a feeling of weakness but again these wear off with time. Symptoms of cerebrovascular insufficiency associated with effective lowering of blood pressure may also occur, including dizziness, light-headedness and faintness. If such symptoms occur, dosage should be reduced. Symptoms due to postural hypotension are fewer and less severe with Dopamet than with other hypotensive agents and exercise hypotension rarely occurs. If such symptoms do occur, the dose of Dopamet should be reduced. Occasionally bradycardia, nasal stuffiness, mild dryness of the mouth and gastro-intestinal symptoms – including distension, constipation, flatus and diarrhoea – may occur. These are generally relieved by reducing the dosage. Vomiting has been reported in very few patients and sore or black tongue has been observed rarely. Weight gain and oedema occur infrequently and are usually relieved by administering a thiazide diuretic. If oedema becomes progressive or other signs of heart failure appear after the addition of a thiazide diuretic, Dopamet should be discontinued. On rare occasions breast enlargement, lactation, impotence, skin rash, mild arthralgia, myalgia, paraesthesias, Parkinsonism, psychic disturbances – including nightmares and reversible mild psychosis – have been reported. A rise in blood urea has been found in some cases. Rarely, urine from patients receiving Dopamet may darken on exposure to air simply because of the chemical breakdown of methyldopa or its metabolites. Cases of acquired haemolytic anaemia have occurred in association with methyldopa. Should clinical symptoms suggest the possibility of anaemia, appropriate tests should be undertaken. If haemolysis is found to be present Dopamet should be discontinued. In addition some patients on continued therapy with methyldopa develop a positive direct Coombs test, but this rarely develops in the first six months of therapy and if it has not developed within 12 months it is not likely to do so. Prior knowledge of a positive Coombs reaction will aid in evaluation of cross-matching for transfusion. If a patient with a positive Coombs reaction shows an incompatible minor cross-match, an indirect Coombs test should be performed. If this is negative, transfusion with blood otherwise compatible in the major cross-match may be carried out. If positive, the advisability of transfusion should be determined by a haematologist.

A reversible thrombocytopenia has occurred on rare occasions and reversible reduction of the white blood cell count has been seen with a primary effect on the granulocytes. The granulocyte count, however, returns promptly to normal when the drug is discontinued. Rare cases of clinical agranulocytosis have been reported. Or rare occasions fever occurs, usually within the first three weeks of administering methyldopa, in some cases accompanied by eosinophilia or abnormalities in one or more liver function measurements. Jaundice with or without fever may also occur, usually within the first two to three months of therapy. In some patients the findings are consistent with cholestasis. Rare cases of fatal hepatic necrosis have been reported. It is advisable to take a total and differential white blood cell count and to perform liver function tests at intervals during the first 6–12 weeks of treatment, or if the patient develops an unexplained fever. Should fever, abnormality in the liver function or jaundice occur, therapy should be withdrawn. Dialysis may remove methyldopa. Hypertension may therefore, recur after this procedure.

Rarely involuntary choreoathetotic movements have been observed during therapy with methyldopa in patients with severe bilateral cerebrovascular disease. Should these movements occur, therapy should be discontinued.

When a thiazide diuretic is added to the dosage regimen, an excessive drop in blood pressure may occur so that the dosage of Dopamet may be reduced by half when a thiazide is used additionally. Careful observation of changes in blood pressure must be made. If Dopamet is added to the regimen of a patient taking a thiazide diuretic then the initial dosage should be limited to 375 mg per day for the first two days and the dosage increased gradually at intervals of not less than two days until adequate control of the blood pressure is obtained.

Treatment of overdose: Gastric lavage may be helpful if carried out within a reasonable time after ingestion and can be assisted by dialysis if the overdose has been substantial. Other treatment should be symptomatic, with general support provided to maintain cardiac output, blood volume, electrolyte balance and urinary output.

Pharmaceutical precautions Store in a cool dry place and protect from light.

Legal category POM.

Package quantities *Tablets 125 mg:* Containers of 250.

Tablets 250 mg: Containers of 250, 1,000 and 2,500.

Tablets 500 mg: Containers of 250 and 500.

Further information 'Dopamet' is an effective hypotensive agent which possesses significant advantages over the ganglion blocking and postganglion blocking agents, controlling high blood pressure throughout the day and night after a basic regimen particular to the patient has been established. It usually reduces supine as well as standing blood pressure and produces little or no postural or exertional hypotension. Normal or elevated plasma renin activity may decrease in course of methyldopa therapy.

DRYPTAL* TABLETS 40 mg

Presentation White Frusemide Tablets BP 40 mg marked 'BERK 2B2' single break line.

Uses Diuretic. Oedema of cardiac, hepatic or renal origin. Pulmonary oedema. Toxaemia of pregnancy. Mild or moderate hypertension.

Dosage and administration The usual initial dosage is 1 tablet daily, thereafter adjusted to the minimum effective dose which may range from $\frac{1}{2}$ tablet (20 mg) on alternate days to 3 tablets (120 mg) daily.

Children: From 1 to 3 mg/kg body weight.

Contra-indications, warnings, etc Dryptal is contra-indicated in the presence of electrolyte deficiency, hepatic cirrhosis or digitalis intoxication and should be used with great caution in advanced renal failure. Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention. Cephaloridine nephrotoxicity may be in-

creased by concomitant administration of potent diuretics such as frusemide.

During prolonged use and at high dosage a close check should be kept upon plasma electrolytes.

Dryptal may potentiate the action of cardiac glycosides and of hypotensive agents, the dosage of which may need to be reduced. Dryptal may also precipitate diabetes, or necessitate increased dosage of insulin.

Serum uric acid levels tend to rise during treatment with Dryptal and an acute attack of gout may occasionally be precipitated.

Other reported side-effects include nausea, gastric upset and malaise. The incidence of allergic reactions such as skin rashes is very low but when these occur treatment should be withdrawn. Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Only when it is essential should Dryptal be given in the first trimester of pregnancy or to nursing mothers.

Treatment of overdose: Correct dehydration and electrolyte depletion. Reversible deafness may occur.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category POM.

Package quantities Containers of 50, 250 and 1,000.

Further information Nil.

Product licence number 0152/0083.

DRYPTAL* TABLETS 500 mg

Presentation Yellow, flat, bevel-edged Frusemide Tablets BP 500 mg engraved Berk 3B2 on one side and with a double breakline on the other.

Uses Diuretic for the management of oliguria due to acute or chronic renal insufficiency with a GFR below 20 ml/minute.

Dosage and administration In patients with chronic renal insufficiency an initial daily dose of 250 mg ($\frac{1}{2}$ tablet) is employed. If a satisfactory diuresis is not produced then the dose may be increased in steps of 250 mg at four to six hourly intervals up to a maximum dose of 2,000 mg (4 tablets) as a single dose.

In cases of acute renal failure which have been initially controlled using Dryptal injection oral therapy may be substituted for parenteral therapy regarding one 500 mg tablet as approximately equal to 250 mg of injection. Appropriate dosage adjustments may then be made according to the observed clinical response.

Contra-indications, warnings, etc During treatment with high-dosage forms of Dryptal, fluid balance should be carefully controlled. In the case of patients with shock, steps should be taken to normalise blood pressure and circulating blood volume before commencing therapy. Regular checks of plasma electrolytes, particularly sodium, potassium, chloride and bicarbonate should be carried out, and electrolyte replacement therapy instituted if necessary.

Contra-indications: Dryptal tablets 500 mg are contra-indicated in renal failure as a result of poisoning by nephrotoxic or hepatotoxic agents and in renal failure associated with hepatic coma.

Warnings: The dosage of concurrently administered

cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Precautions: The safety of high dosage frusemide in pregnancy has not been established and Dryptal tablets 500 mg should be used with caution, weighing potential benefit to the patient against possible hazard to the foetus.

Treatment of overdose: Correct dehydration and electrolyte depletion. Reversible deafness may occur.

Side-effects: Dryptal tablets 500 mg are generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to cause withdrawal of treatment. The incidence of allergic reactions such as skin rashes is very low but when these occur treatment should be withdrawn. In common with other sulphonamide-based diuretics hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated. Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category POM.

Package quantities Containers of 100.

Further information Nil.

Product licence number 0152/0145.

DRYPTAL* INJECTION 20 mg/2 ml

Presentation Dryptal Injection 20 mg contains 20 mg Frusemide BP in 2 ml.

Uses Dryptal is a diuretic recommended for use in all indications when a prompt and effective diuresis is required. Indications include cardiac oedema, renal oedema, peripheral oedema due to mechanical obstruction or changes in the walls of the veins, ascites, toxæmia of pregnancy, hypertension and miscellaneous conditions such as acute barbiturate poisoning, after prostatectomy and in cases where other diuretics have failed to produce the desired effect.

Dosage and administration Dryptal has an exceptionally wide therapeutic range the effect being proportional to the dosage. Dryptal is best given as a single dose either daily, on alternate days, or on three successive days of the week.

Parenteral administration: Intravenous injections of Dryptal must be given slowly. In cases of emergency or when oral therapy is precluded an initial dose of 20–40 mg (1–2 ampoules) i.m. or i.v. is recommended. Further adjustment may then be necessary according to the observed clinical response.

Parenteral doses for children range from 0.5–1.5 mg/kg body weight.

Contra-indications, warnings, etc

Contra-indications: Dryptal is contra-indicated in electrolyte deficiency and precomatose states associated with liver cirrhosis.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Infusion rates in excess of 4 mg/min are associated with an increased risk of ototoxicity, usually reversible hearing loss.

Precautions: Caution should be observed in patients liable to electrolyte deficiency.

The use of Dryptal during the first trimester of pregnancy should be subject to the normal precautions which apply to any drug at this time. As Dryptal may inhibit lactation it should be used with caution in nursing mothers.

Treatment of overdose: Correct dehydration and electrolyte depletion. Reversible deafness may occur.

Side-effects: Dryptal is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to cause withdrawal of treatment.

The incidence of allergic reactions such as skin rashes is very low but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Dryptal should be stored in a cool dry place protected from light in the original containers.

Injections of Dryptal should not be mixed with any other preparation. Opened ampoules should be used immediately and any remainder discarded.

Legal category POM.

Package quantities Dryptal ampoules are available in packs of 10 × 2 ml.

Further information Dryptal produces a prompt and effective diuresis which lasts for approximately two hours following parenteral administration. Therefore the time of administration can be adjusted to suit the patient's requirements.

Product licence number 0152/0149.

DRYPTAL* INJECTION 50 mg/5 ml

Presentation Dryptal injection 50 mg contains 50 mg Frusemide BP in 5 ml.

Uses Dryptal is a diuretic recommended for use when a prompt and effective diuresis is required. The intravenous formulation is appropriate for use in emergencies. Indications include cardiac oedema, pulmonary oedema, hepatic oedema, renal oedema and cases in which other therapy has failed to produce the desired response.

Dosage and administration Dryptal injection must always be given slowly. The diuretic effect of Dryptal is

proportional to the dosage. Up to 50 mg may be given initially, if larger doses are required, they should be given by slow infusion and titrated according to the response. In such cases the use of Dryptal 250 mg ampoules should be considered.

Contra-indications, warnings, etc Intravenous injections of Dryptal, **must** always be given slowly.

Contra-indications: Dryptal is contra-indicated in electrolyte deficiency and pre-comatose states associated with liver cirrhosis.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Infusion rates in excess of 4 mg/min are associated with an increased risk of ototoxicity, usually reversible hearing loss.

Precautions: Caution should be observed in patients liable to electrolyte deficiency. The use of Dryptal during the first trimester of pregnancy should be subject to the normal precautions which apply to any drug at this time.

As Dryptal may inhibit lactation it should be used with caution in nursing mothers.

Treatment of overdose: Correct dehydration and electrolyte depletion. Reversible deafness may occur.

Side-effects: Dryptal is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to cause withdrawal of treatment.

The incidence of allergic reactions such as skin rashes is very low but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics hyperuricaemia may occur and in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Dryptal 50 mg should be stored in a cool dry place protected from light in the original containers. Injections of Dryptal should not be mixed with any other preparations. Opened ampoules should be used immediately and any remainder discarded.

Legal category POM.

Package quantities Dryptal ampoules 50 mg are available in packs of 10 × 5 ml.

Further information Nil.

Product licence number 0152/0149.

DRYPTAL* INJECTION 250 mg/25 ml

Presentation Dryptal 250 mg ampoules contain 250 mg Frusemide BP in 25 ml.

Uses Dryptal 250 mg is a diuretic preparation for the management of oliguria due to acute or chronic renal insufficiency with a GFR below 20 ml/minute.

Dosage and administration Dryptal 250 mg should be administered by intravenous injection at a rate not exceeding 4 mg/min.

The recommended initial dose is one 25 ml ampoule (250 mg) diluted in approximately 225 ml Sodium Chloride Injection BP or Ringer's Solution for Injection administered over one hour. This gives an approximate drip rate of 80 drops/minute, ensuring that the infusion is at the level of 4 mg/minute.

If a satisfactory increase in urine output, such as 40–50 ml/hour, is not attained within the next hour a second infusion of two 25 ml ampoules (500 mg) in an appropriate infusion fluid should be given, the total volume of the infusion being governed by the patient's state of hydration. If a satisfactory output is still not achieved within one hour of the end of the second infusion, a third infusion consisting of four 25 ml ampoules (1,000 mg) can be given. The rate of infusion should not exceed 4 mg/min.

If the third infusion using the maximum intravenous dose of 1,000 mg over four hours is not effective, then dialysis will probably be required.

In oliguric or anuric patients with significant fluid overload, it may not be practicable to administer high-dose Dryptal injection by the method suggested above. Under these circumstances, the use of a constant-rate infusion pump (e.g. Sage pump) with micrometer screw-gauge adjustment may be considered for direct administration of the injection in to the vein. The rate of administration should not exceed 4 mg/min.

If the Dryptal infusion produces a satisfactory response of 40–50 ml/hour, then the effective dose (up to 1,000 mg) can be repeated every 24 hours. Alternatively, maintenance therapy can be continued with oral Dryptal 500 mg tablets when one 500 mg tablet may be regarded as being approximately equal to one 250 mg ampoule. Appropriate dosage adjustments may then be made according to the observed clinical response.

Contra-indications, warnings, etc During treatment with high-dosage forms of Dryptal, fluid balance should be carefully controlled. In the particular case of patients with shock, steps should be taken to correct the blood pressure and circulating blood volume before commencing therapy. Regular checks of plasma electrolytes, particularly sodium, potassium, chloride and bicarbonate, should be carried out, and electrolyte replacement therapy instituted accordingly.

Intravenous injections of Dryptal **must** be given slowly.

Infusion rates in excess of 4 mg/min are associated with an increased risk of ototoxicity, usually reversible hearing loss.

Contra-indications: Dryptal injection 250 mg is contra-indicated in renal failure as a result of poisoning by nephrotoxic or hepatotoxic agents and in renal failure associated with hepatic coma.

Warnings: The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Precautions: The safety of high dosage frusemide in pregnancy has not been established and Dryptal injection 250 mg should be used with caution depending on the

severity of the condition. As Dryptal may inhibit lactation it should be used with caution in nursing mothers.

Treatment of overdosage: Correct dehydration and electrolyte depletion. Reversible deafness may occur.

Side-effects: Dryptal injection 250 mg is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to cause withdrawal of treatment.

The incidence of allergic reactions such as skin rashes is very low but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Dryptal ampoules 250 mg should be stored in a cool place protected from light. Frusemide may precipitate in solutions of low pH and therefore dextrose solutions are not suitable infusion fluids for Dryptal injections 250 mg. The injection solution should not be mixed with other drugs in the infusion bottle.

Opened ampoules should be used immediately and any remainder of either the ampoule content or the prepared infusion solution should be discarded.

Legal category POM.

Package quantities Dryptal ampoules 250 mg are available in packs of 10 × 25 ml.

Further information Diuresis should commence within a few minutes and last for approximately two hours. A diuretic effect is seen during the infusion and its duration is related to the infusion time.

Product licence number 0152/0149.

ERYCEN[®]

Presentation Plain orange film-coated Erythromycin Tablets BP 250 mg (Erythromycin base).

Uses Infections caused by erythromycin-sensitive organisms especially Gram-positive pyogenic cocci and some Gram-negative bacteria, notably *Haemophilus* and *Neisseria* groups.

Dosage and administration *Adults:* 1 tablet every four to six hours increased to 4 g or more per day in unusually severe infections.

Contra-indications, warnings, etc Known sensitivity to erythromycin. Use in conjunction with other anti-infectives, except when specifically warranted.

Precautions: Caution should be exercised in administering erythromycin to patients with impaired hepatic function, since the antibiotic is excreted principally by the liver.

Side-effects are rare and usually mild. Nausea, vomiting, diarrhoea and pruritus have occurred. Allergic reactions are rare and mild, although anaphylaxis has occurred. Treatment should not usually be continued for longer than ten days. The rare possibility of superinfection caused by overgrowth of non-susceptible bacteria or fungi should be borne in mind during prolonged or repeated therapy, especially when other antibacterial agents are simultaneously employed.

Treatment of overdosage: It is unlikely that serious symptoms will occur; observation and conservative management are indicated.

Pharmaceutical precautions Store in a cool dry place.

Package quantities Containers of 100 and 500 tablets.

Legal category POM.

Further information Erythromycin is bacteriostatic and bactericidal, depending on the concentration. Its antimicrobial spectrum is similar to that of penicillin G but it shows increased activity against some Gram-negative bacteria.

Product licence number 0152/0132.

IMBRILON[®]

Presentation Opaque yellow Indomethacin Capsules BP 25 mg (marked 'BERK 1J3 25') and 50 mg (marked 'BERK 2J3 50').

Cream-coloured Indomethacin Suppositories BP 100 mg. The base is polyethylene glycol.

Uses Non steroidal analgesic and anti-inflammatory agent. Indicated in active rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout. Also may be indicated in severe acute periarticular disorders such as bursitis, tendinitis, synovitis, tenosynovitis and capsulitis.

Dosage and administration Indomethacin Capsules should always be given with food, milk or an antacid to lessen the chance of gastro-intestinal disturbance.

Imbrilcon Suppositories should be given singly, one night and morning.

Adults: 50–100 mg daily.

Children: Paediatric dosage not established.

Contra-indications, warnings, etc

Contra-indications: It is not known if indomethacin is safe to use in children or in pregnancy or during lactation and it should not be given to such patients.

Active peptic ulcer, a history of recurrent gastro-intestinal lesions, sensitivity to indomethacin or to aspirin are also contra-indications.

Precautions and drug interactions: Indomethacin should be used with caution in patients with hepatic or renal dysfunction. Hepatitis and jaundice have been reported rarely. Patients should be warned not to drive or operate machinery, if they become dizzy.

In common with other anti-inflammatory analgesic antipyretic agents, indomethacin may mask the signs and symptoms of infectious disease and this should be borne in mind in order to avoid delay in starting treatment for infection.

Indomethacin should be used with caution in patients with an existing, albeit controlled, infection.

Particular care should be taken with older patients who are more susceptible to side-effects from indomethacin.

Treatment of overdosage: Gastric lavage should be given if indomethacin is considered still to be part of the stomach contents.

Otherwise supportive therapy is required and a watch should be kept for gastro-intestinal bleeding for several days.

Warnings and adverse effects: It must be expected that about 20% of patients will complain of side-effects, but starting treatment at a low dosage and increasing it gradually until symptomatic relief is obtained will minimise their incidence.

The most common side-effects are headache, dizziness and dyspepsia. If headache persists, even after dosage reduction, indomethacin should be withdrawn.

Other CNS side-effects which may occur include mental confusion, depression, convulsions, coma, de-personalisation and tinnitus. These are often transient and disappear with time or on reduction of dosage.

Indomethacin may aggravate psychiatric disorders, epilepsy and Parkinsonism.

Gastro-intestinal disorders which occur most frequently are nausea, anorexia, vomiting, epigastric distress, abdominal pain and diarrhoea. Giving indomethacin with food, milk or antacids lowers the incidence of these side-effects. Ulceration of the oesophagus, stomach or duodenum may also occur, accompanied by haemorrhage and perforation (a few fatalities have been reported). Gastro-intestinal bleeding without obvious ulceration may also occur. If this happens indomethacin treatment should be discontinued.

Blood dyscrasias, particularly thrombocytopenia, have been reported.

Blurred vision and orbital and peri-orbital pain are seen infrequently. Corneal deposits and retinal disturbances have been reported in some patients with rheumatoid arthritis on prolonged therapy with indomethacin, and ophthalmic examinations are desirable in patients given prolonged treatment.

Oedema and increased blood pressure also sometimes occur, as does haematuria.

Hypersensitivity reactions include pruritus, urticaria, angitis, erythema nodosum. Skin rash and hair loss may also occur.

Acute respiratory distress including sudden dyspnoea and asthma, have been reported on rare occasions. Bronchospasm may be precipitated in patients suffering from, or with a previous history of bronchial asthma or allergic disease.

Pharmaceutical precautions Containers should be kept closed, in a cool place and protected from light.

Legal category POM.

MELITASE*

Presentation White Chlorpropamide Tablets BP, scored on reverse. 100 mg marked 'BERK 3D4' and '50 mg marked 'BERK 4D4'.

Uses As an oral hypoglycaemic agent in uncomplicated table, mild and moderately severe, nonketotic, maturity-onset type diabetes mellitus, where dietary treatment alone has failed. Chlorpropamide can often be used in

patients of this type in place of insulin. Its hypoglycaemic effect, however, occurs only when the β cells of the islet tissue in the pancreas retain some functional capacity. It has no effect on glucose tolerance.

Chlorpropamide is valueless in the treatment of severe diabetes.

Chlorpropamide should not be used to replace dietetic therapy where this is indicated.

Dosage and administration In uncomplicated maturity onset diabetes, the initial and maximum dose, taken as two 250 mg tablets, is 500 mg, which should be reduced to a maintenance level as soon as possible. Since three days are necessary for blood levels of chlorpropamide to become stable at a particular dosage changes should not be made at shorter intervals and should be in steps of 50–100 mg. Most patients are stabilised on a dosage of 100–375 mg daily.

Several weeks may be required to achieve a correct dosage level and the patient's blood sugar should be monitored throughout where possible and the urine tested for glycosuria at least four times daily in all cases.

Elderly patients should be started on half the usual dosage since they are often very sensitive to the sulphonylureas and may develop hypoglycaemia if given full dosage.

Contra-indications, warnings, etc 'Melitase' is contra-indicated in diabetic ketosis diabetes complicated by fever trauma or gangrene and in patients with impaired renal hepatic or thyroid function.

Patients taking 'Melitase' may become intolerant of alcohol, a reaction not unlike the disulfiram alcohol reaction being produced. Patients should be warned of this possibility.

The hypoglycaemic effect of 'Melitase' may be increased by coumarin derivatives, MAO inhibitors, salicylates and propranolol.

Because of the possibility of blood dyscrasia a white cell count should be performed and should be repeated in five days should an infection or symptoms of infection appear.

'Melitase' should not be used as a substitute for dietary treatment.

Gastric and intestinal disturbance, jaundice, headache, tinnitus, weakness, paraesthesia and skin rashes have been observed. Blood dyscrasias have been reported and include agranulocytosis, leucopenia and thrombocytopenia. A prolonged hypoglycaemia may very occasionally be produced by chlorpropamide.

Treatment of overdose: Hypoglycaemic coma can occur up to five days after an overdose. Repeated infusions of intravenous glucose may be required. The patient should be carefully monitored as sudden relapses are likely. Gastric lavage and haemodialysis will help to remove the excess Melitase.

Pharmaceutical precautions No special precautions.

Legal category POM.

MUCODYNE*

Presentation *Mucodyne Syrup*: Clear amber syrup containing carbocisteine 250 mg in each 5 ml.

Mucodyne paediatric syrup: Clear red syrup containing carbocisteine 125 mg in each 5 ml.

Mucodyne Capsules: Opaque yellow capsules marked 'MUCODYNE 375', each containing carbocisteine 375 mg.

Uses Mucolytic agent for the adjunctive therapy of respiratory tract disorders characterised by excessive or viscous mucus including Glue Ear in children.

Mucodyne reduces the viscosity of bronchial secretions and facilitates expectoration. There is also evidence that during treatment with Mucodyne the physical and chemical characteristics of the mucin components of sputum return to a more normal pattern, with reduction of fucose and sulphate content and an increase in the proportions of sialomucins.

Dosage and administration *Mucodyne Syrup*: *Adults*: 15 ml three times a day initially, reduced to 10 ml three times a day when a satisfactory response has been obtained.

Mucodyne paediatric syrup: 2–5 years: 2.5–5 ml four times a day.

5–12 years: 10 ml three times a day.

Mucodyne capsules: *Adults*: Two capsules three times a day, reduced to one capsule four times a day when a satisfactory response has been obtained.

Contra-indications, warnings, etc Although tests in mammalian species have revealed no teratogenic effects, Mucodyne is not recommended during the first trimester of pregnancy.

There have been very rare reports of skin rashes or gastro-intestinal bleeding occurring during treatment with Mucodyne.

Treatment for overdose: Gastric lavage may be beneficial, followed by observation. Gastrointestinal disturbance is the most likely symptom of Mucodyne overdose.

Pharmaceutical precautions Mixture with linctus of pholcodeine causes precipitation of carbocisteine from solution. Dilution of Mucodyne Syrup may be effected with unpreserved Syrup BP but diluted preparations should not be kept for more than 14 days.

Legal category POM.

Package quantities *Mucodyne Syrup*: Bottles of 200 ml. Bottles of 300 ml with dosage cap.

Mucodyne paediatric syrup: Bottles of 300 ml with dosage cap.

Mucodyne Capsules: Containers of 100.

Further information Nil.

Capsules 0152/0098.

NITRADOS*

Presentation White, round, flat, bevel-edged Nitrazepam Tablets BP, marked BERK 1N4, with single break line on reverse, each containing 5 mg Nitrazepam BP.

Uses Hypnotic of the benzodiazepine group, indicated for the relief of insomnia due to anxiety or stress. It may also be used as adjunctive therapy in the treatment of sleep disturbances due to organic causes.

At therapeutic doses nitrazepam induces sleep lasting some six to eight hours, from which the sleeper may be readily aroused if necessary. There is less confusion upon awakening than is observed with the barbiturates, especially in the elderly.

Dosage and administration *Adults*: Usually 5 mg before retiring. This may be increased to 10 mg when necessary or to 20 mg in hospitalised patients.

Smaller doses, 2.5–5 mg are more suitable for elderly patients.

Children: Nitrados is not recommended for the routine treatment of children but 2.5 mg may be given when necessary to children aged one to six years and 5 mg to children aged seven years or older.

Contra-indications, warnings, etc Nitrados should only be used with great caution in patients with impairment of renal or hepatic function, or who are elderly or debilitated. Particular consideration should be given to respiratory function.

Concomitant administration with CNS depressants (including alcohol), general anaesthetics, narcotic analgesics, monoamine oxidase inhibitors and anti-depressants may result in an accentuation of their effects.

Patients should be warned of the possibility of drowsiness occurring, particularly in the first few days of therapy and advised to moderate their use of alcohol. They should also be warned not to drive or operate machinery if Nitrados affects their alertness.

Although animal experiments have revealed no teratogenic effects, nitrazepam is not recommended during the first trimester of pregnancy.

Side-effects are few at the recommended dosage although fatigue, drowsiness or light-headedness are occasionally noted and confusion may occur in the elderly.

Excessive or prolonged use of nitrazepam may result in the development of psychological dependence with withdrawal symptoms on discontinuance.

Treatment of overdose: Drowsiness and ataxia will be the predominant initial symptoms and the patient may be unconscious for up to 36 hours. Gastric lavage may be useful but Nitrados causes few serious problems in overdose. In children behavioural changes are likely.

Pharmaceutical precautions Protect from light, heat and moisture.

Legal category POM.

Package quantities Containers of 50 and 500 tablets

Further information Nil.

Product licence number 0152/0130.

NODILON*

Presentation White tablets each containing 80 mg Trimethoprim BP and 400 mg Sulphamethoxazole BP.

Uses Antibacterial agent. Nodilon is effective in-vitro against a wide range of Gram-positive and Gram-negative organisms. It is not active against *Mycobacterium tuberculosis* or *Treponema pallidum*.

Pseudomonas aeruginosa is usually insensitive.

Nodilon is of value in the treatment of the following.

Respiratory tract infections:

Acute and chronic bronchitis, bronchiectasis, empyema, lung abscess, lobar- and broncho-pneumonia, Pneumocystis carinii pneumonitis, otitis media and sinusitis.

Genito-urinary tract infections:

Urethritis, cystitis, pyelitis, pyelonephritis and prostatitis. Gonorrhoea.

Gastro-intestinal tract infections:

Typhoid and paratyphoid fevers, chronic carrier states with Salmonella typhi and paratyphi, cholera, shigellosis.

Skin infections:

Pyoderma, abscesses and wound infections.

Other bacterial infections:

Acute and chronic osteomyelitis, acute brucellosis, septicaemias and other infections caused by sensitive organisms.

Dosage and administration *Adults:* Standard dosage: 2 tablets twice daily. Maximum dosage (for particularly severe infections): 3 tablets twice daily.

Minimum dosage and dosage for long-term treatment (more than 14 days): 1 tablet twice daily.

Children over 12 years: As for adults.

6-12 years: 1 tablet twice daily.

In acute infections, Nodilon should be given for at least five days or until the patient has been symptom-free for two days.

In prostatitis and brucellosis, treatment should last for a period of at least 4 weeks.

Dosage in gonorrhoea: In uncomplicated gonorrhoea 4 tablets every 12 hours for two days or 5 tablets followed eight hours later by a further dose of 5 tablets is recommended.

In the treatment of Pneumocystis carinii pneumonitis the dosage is 20 mg Trimethoprim/100 mg Sulphamethoxazole/kg/day in 2 divided doses for 2 weeks.

Dosage recommendations in renal impairment: If Nodilon is given to patients with renal impairment then the following dosage scheme, based on creatinine clearance, is suggested (no information is available for children with renal failure).

Creatinine clearance:

Above 25 ml/min	Standard dosage.
15-25 ml/min	Standard dosage for a maximum of three days followed by half the standard dosage every 24 hours.
Below 15 ml/min	Not to be administered unless haemodialysis facilities are available. Under this condition half the standard dosage may be given every 24 hours.

Measurements of plasma concentrations of sulphamethoxazole at intervals of two to three days are recommended in samples obtained 12 hours after administration of Nodilon. If the concentration of total Sulphamethoxazole exceeds 150 mcg/ml, then treatment should be interrupted until the value falls below 120 mcg/ml.

Contra-indications, warnings, etc Contra-indicated in severe renal insufficiency where repeated measurements of the plasma concentration cannot be performed. In cases with renal impairment a modified dosage schedule as described above is indicated. In such patients, measurement of the plasma concentration of

the drug is advisable, and an adequate urinary output should be maintained.

Contra-indicated in patients showing marked liver parenchymal damage or blood dyscrasias.

Nodilon should not be given to patients with a history of trimethoprim, sulphonamide or co-trimoxazole sensitivity.

Nodilon should not be given to premature babies nor to full-term infants during the first six weeks of life. The drug should not be given during pregnancy. The usual caution in prescribing any drug for women of child-bearing age should also be exercised with Nodilon.

If Nodilon treatment is prolonged, especially in patients with suspected impairment of folate metabolism, it is suggested that complete blood counts including thrombocytes should be performed fortnightly for the first month, and then monthly.

Nausea, vomiting, glossitis and skin rashes can occur. Isolated cases of severe skin sensitivity reactions such as erythema multiforme (Stevens-Johnson syndrome), and epidermal necrolysis (Lyell syndrome) have occurred.

As Nodilon contains a sulphonamide, the possibility of blood dyscrasias, like those associated with sulphonamides, should be borne in mind.

The changes reported with Co-trimoxazole consist mainly of thrombocytopenia, purpura, leucopenia, neutropenia and very rarely agranulocytosis. They have usually proved to be reversible on withdrawal of the drug. Elderly patients are more susceptible to these blood changes.

During long-term therapy, isolated cases of megaloblastic changes in the bone marrow have been reported; these are reversible with calcium folinate therapy.

Due to the relatively high degree of protein binding of sulphamethoxazole, patients receiving oral anticoagulants of the coumarin group should be monitored to ensure appropriate anticoagulant control.

Patients receiving pyrimethamine in doses in excess of 25 mg weekly who are also receiving Nodilon should have their blood pictures monitored because of the occasional report of megaloblastic anaemia apparently occurring in these circumstances.

Care should be taken when giving Nodilon to diabetic patients on sulphonylureas as it may increase the hypoglycaemic action of these drugs.

Treatment of overdosage: Gastric lavage may be useful. Forced diuresis is advised, and alkalisation of the urine will increase the elimination of the sulphamethoxazole. Calcium folinate 3-6 mg given intramuscularly for five to seven days should counteract the bone-marrow depressant effects of trimethoprim. General supportive measures should be taken.

Pharmaceutical precautions Store in a cool dry place. Protect from light.

Legal category POM.

Package quantities Securitainers of 50 and 1,000 tablets.

Further information Absorption by the oral route is rapid; significant plasma levels are obtained within an hour. Peak levels are reached between two and four hours and are maintained over a period of 12 hours.

In the treatment of tonsillo-pharyngitis due to Group A beta-haemolytic streptococci, eradication of these organisms from the oro-pharynx is less rapid than with some other antibiotics.

Both sulphamethoxazole and trimethoprim may be

found in breast milk but this does not contraindicate the use of Nodilon in lactating mothers.

Product licence number 0152/0163

PACITRON®

Presentation Film-coated, oblong orange-yellow tablets marked 'PCT 500', each containing L-tryptophan 500 mg.

Uses L-tryptophan is a metabolic precursor of 5-hydroxytryptamine (serotonin) which acts as a neurotransmitter in the central nervous system. It is indicated in endogenous and reactive depression and in depressive phases of manic-depressive psychosis.

Dosage and administration *Adults:* 3-6 g daily in divided doses. In the case of outpatients, it is generally found that a dosage of 2 tablets three times a day is sufficient. In more severely depressed patients, especially those in hospital, dosage of 12 tablets daily may be required. The last dose should be taken before bed.

Children: There is insufficient evidence to establish paediatric dosage and use is not recommended in children.

L-tryptophan may also be given to patients responding inadequately to monoamine oxidase inhibitors (MAOI), but when the two are given together the side-effects of both may be increased. Pacitron should therefore be introduced more slowly, beginning at 1 tablet daily for the first week and 2 tablets daily for the second. Normal dosage may be given from the third week onwards, but Pacitron should be discontinued at once if headache or blurring of vision occurs.

Contra-indications, warnings, etc The use of Pacitron should not replace standard management in patients with severe depression and/or a risk of suicide.

There is no absolute contra-indication to the use of this dosage of L-tryptophan, which is a normal and essential constituent of the diet. When given along with MAOI it may sometimes provoke a reaction resembling alcoholic intoxication, and when taken alone it may occasionally cause drowsiness particularly in the early stages of treatment. Patients should be warned to avoid driving or handling machinery until their reaction is known.

In patients taking Pacitron along with or following treatment with phenothiazines or benzodiazepines, there have been rare reports of sexual disinhibition and of reversible Parkinsonian-like rigidity and dyskinesias. Since these other drugs may reduce plasma binding of tryptophan, it is recommended that initial dosage of Pacitron should not exceed 1 tablet thrice daily if the patient is taking or has just finished treatment with a major tranquilliser.

Nausea occurs in a few patients early in treatment, and may be of central origin, but can usually be relieved by taking Pacitron after food.

There is as yet no information on the effects of prolonged administration of Pacitron. It is therefore advised that after six months' therapy at full dosage, the patient's condition should be re-assessed with a view to lowering or discontinuing medication unless clear evidence of benefit from the use of the product is present.

Pacitron is not advised, except for relatively short periods, in patients with active bladder disease or known bladder lesions.

The safety of large doses of L-tryptophan during pregnancy has not been established and use in pregnant women and nursing mothers is not advised.

Treatment of overdosage: No serious consequences are known to result from overdosage. Gastric lavage might be helpful followed by observation and general supportive measures.

Pharmaceutical precautions No special precautions.

Legal category POM.

Package quantities Containers of 100 tablets.

Further information As with other antidepressant therapy, the full effect of Pacitron may not develop for two or three weeks and patients should be told this.

Product licence number 0152/0117.

PONOXYLAN®

Presentation White gel containing 10% w/w polynoxylin.

Uses Topical broad spectrum antibacterial and healing agent.

Ponoxylan Gel is indicated in all infective skin conditions including furunculosis and pustular acne. It is of great value in burns wounds and cutaneous infected conditions including staphylococcal nasal infections. It reduces inflammation in intertrigo and many eczematoid eruptions.

It is of considerable value in dermatology as an alternative to broad spectrum antibiotic therapy with or without corticosteroids.

Dosage and administration Ponoxylan Gel should be gently applied to the affected areas.

Contra-indications, warnings, etc There are no known contra-indications. There are no special precautions to be taken with Ponoxylan Gel.

Ponoxylan is virtually insoluble and is therefore not absorbed into the blood stream. Systemic toxicity is thus nil. There have been no reports of sensitivity to polynoxylin. A very occasional patient may experience stinging or pain following application.

Pharmaceutical precautions No known incompatibilities.

Legal category P.

Package quantities Tubes of 25 g.

Further information Nil.

Product licence number 0152/5042.

PRAMIDEX®

Presentation White Tolbutamide Tablets BP 500 mg marked 'BERK 5E5', single break line.

Uses As an oral hypoglycaemic agent in the treatment of mild and moderately severe uncomplicated diabetes mellitus, particularly of the maturity-onset type, where control cannot be achieved by diet alone.

The hypoglycaemic effect of tolbutamide only occurs when the β cells of the islet tissue in the pancreas are intact and when they retain some functional capacity. It is therefore presumed that tolbutamide stimulates the

pancreas to a greater insulin output. It has no effect on glucose tolerance.

It follows that Pramidex has no place in the treatment of the severe diabetic, but finds its chief use in the treatment of maturity-onset diabetes, responding inadequately to dietary treatment alone. In some of these patients it can replace low doses of insulin or reduce the requirement for high doses.

Dosage and administration Pramidex should be given with or just before meals for optimum control of blood sugar.

1st day: 4–8 tablets.

2nd day: 3–6 tablets.

3rd day: 2–4 tablets.

Maintenance: 1–3 tablets daily, the exact dose being that sufficient to correct glycosuria and hyperglycaemia without producing hypoglycaemia. The full effect of therapy may take up to a week to develop.

Where a patient is already taking insulin, the change to tolbutamide may be effected directly where the dose of insulin is 15 units or less per day. Where insulin is being given in greater amounts, the number of units should be decreased over several days and a watch should be kept for glycosuria.

Contra-indications, warnings, etc Diabetes complicated by fever, trauma or gangrene and diabetic retinosis. Impaired renal, hepatic or thyroid function. Pramidex is contra-indicated during pregnancy. Sulphafurazole is thought to potentiate the action of tolbutamide and the concurrent administration of these two drugs is contra-indicated.

Gastric irritation may occur and may be reduced by giving in divided doses. Skin sensitisation weakness, paraesthesias, tinnitus, headache, intolerance to alcohol and jaundice have all been observed. Reversible blood dyscrasias have also occurred. A very small proportion of patients are thought to have difficulty in metabolising tolbutamide and in consequence develop hypoglycaemia even on low dose.

If fever or a sore throat occurs, a white cell count should be performed and should be repeated after five days as blood abnormalities may develop slowly.

Severe hypoglycaemia has occurred with the concomitant administration of coumarins.

The possibility of thrombocytopenia should be borne in mind and a platelet count performed if indicated.

Cases which respond initially to tolbutamide may elapse at a later date and this should be considered as possibility should glycosuria or hyperglycaemia appear.

Pramidex should not be used as a substitute for dietary treatment in obese diabetics.

Treatment of overdosage: Gastric lavage. Hypoglycaemia may be counteracted with dextrose and, if necessary, glucagon.

Pharmaceutical precautions No special precautions.

Legal category POM.

Package quantities Containers of 500 tablets.

Further information Nil.

Product licence number 0152/0061.

'RIMPERAN'

Presentation *Tablets:* White tablet marked 'PRIM-

PERAN' with single break line on reverse. Each tablet contains 10 mg metoclopramide monohydrochloride.

Lime-coloured syrup: Each 5 ml contains 5 mg metoclopramide monohydrochloride.

Clear ampoules: 10 mg metoclopramide monohydrochloride in 2 ml.

Uses For the relief of upper gastro-intestinal symptoms including heartburn, nausea and vomiting in flatulent dyspepsia gastritis and duodenitis.

As an anti-emetic agent for the treatment of nausea and vomiting accompanying the following conditions.

Intolerance to essential drugs such as digitalis, antibiotics and antibacterials, tuberculostatic agents, cytostatic and cytotoxic drugs.

Gastro-intestinal disorders, including peptic ulcers, gastritis and sequelae of gastrectomy.

Malignant disease.

Uraemic conditions.

Deep X-ray or cobalt therapy.

Post-anaesthetic vomiting.

Barium-meal examinations.

Post-operative gastric hypotonia.

Post vagotomy syndrome.

To facilitate barium-meal examinations:

(a) where barium-meal studies are held up by spasm of the duodenal cap making examination for the presence of the ulcer difficult;

(b) to facilitate examination of the hypotonic stomach with delayed emptying, gastric stasis and pyloric channel syndrome.

To facilitate duodenal intubation procedures.

Dosage and administration The daily dose level of Primperan is based upon 0.5 mg/kg body weight, in divided doses, which in normal circumstances should not be exceeded. It is particularly desirable to adhere to this level in children and young adults.

General therapeutic dosage:

Tablets: Adults: 1 tablet (10 mg) three times daily.

Young adults: (15–20 years): $\frac{1}{2}$ –1 tablet two to three times daily.

Syrup: Adults: Two 5 ml spoonfuls (10 mg) three times daily.

Young adults (15–20 years): One to two 5 ml spoonfuls two to three times daily.

Children (5–14 years): Half to one 5 ml spoonful three times daily.

Ampoules: Adults: 1 ampoule (10 mg) i.m. or i.v. one to three times daily according to the severity of the condition.

Young adults (15–20 years): $\frac{1}{2}$ –1 ampoule i.m. or i.v. one to three times daily.

Children (5–14 years): Up to $\frac{1}{2}$ ampoule i.m. or i.v. one to three times daily.

To facilitate barium meal examinations and small bowel intubations:

Ampoules: Adults: One (10 mg) to two (20 mg) ampoules i.m. or i.v. 5–10 minutes before the examination.

Children (5–14 years): Up to $\frac{1}{2}$ an ampoule, according to age, i.m. or i.v. 5–10 minutes before the examination.

Oral: Adults: Four 5 ml spoonfuls or 2 tablets (20 mg) 10–15 minutes before the examination.

Young adults (15–20 years): Two 5 ml spoonfuls or 1 tablet (10 mg) 10–15 minutes before the examination.

Children (5–14 years): Half to one 5 ml spoonful 10–15 minutes before the examination.

Contra-indications, warnings, etc Since atropine effectively blocks the action of 'Primperan', the concomitant administration of this and other anticholinergic drugs should be avoided.

As both Primperan and phenothiazines may cause benign transient dystonia, care should be exercised in the event of both drugs being prescribed concurrently.

The recommended dosage should not be exceeded, particularly in children, young adults and other patients of low body weight, who may be more liable to dystonic reactions.

Primperan is not recommended during pregnancy, although animal tests in several mammalian species have revealed no teratogenic effect.

'Primperan' has given rise to a remarkably low incidence of side-effects, with absence of serious toxicity and excellent tolerance by oral and parenteral routes. Although rare, drowsiness and dystonic reactions have been reported, these are reversible usually disappearing within 24 hours of stopping treatment.

The rarely occurring symptoms include spasm of facial extra-ocular or cervical muscles which may be constant or rhythmic. There may also be a generalised increase in muscle tone. Anti-Parkinsonian drugs of the anticholinergic type may be used to counteract these reactions.

Treatment of overdosage: Gastric lavage and intensive supportive therapy should be initiated. Dystonic symptoms are likely and may be treated in severe cases with atropine, benztropine or other anticholinergic agents. Generalised convulsions may appear in infants.

Pharmaceutical precautions No known incompatibilities.

Diluent for Syrup: Syrup BP.

Diluent for ampoules: Water for injection BP.

Protect from direct light.

Legal category POM.

Package quantities *Tablets:* Containers of 100 and 500.

Syrup: Bottles of 100 ml.

Ampoules: Boxes of 10 × 2 ml.

Further information Primperan has the unique action of normalising the hypomotile stomach and small intestine and also possesses a powerful antiemetic effect.

Product licence numbers

Tablets 0152/5001

Syrup 0152/5002

Ampoules 0152/5003.

SILBE* INHALANT

Presentation Clear liquid for aerosolisation containing Papaverine Hydrochloride BP 0.95% w/v, Adrenaline Acid Tartrate BP 1% w/v, Atropine Methonitrate BP 0.125% w/v, Chlorbutol BP 1% w/v, Hyoscine Hydrobromide BP 0.050% w/v.

Uses For the treatment of Bronchospasm occurring in asthma.

Dosage and administration Adults should inhale for one to two minutes and children for half to one minute.

Treatment should be started as soon as an attack is imminent and may be repeated two or three times a day.

Contra-indications, warnings, etc 'Silbe' Inhalant is contra-indicated in hyperthyroidism, hypertension, coronary disease.

Side-effects: Palpitations, cardiac dysrhythmias may develop in adrenaline-sensitive patients.

Treatment of overdosage: Gastric lavage if taken by mouth. Observation and intensive supportive therapy.

Pharmaceutical precautions Keep bottles tightly closed.

Legal category POM.

Package quantities Bottles of 25 ml.

Further information Nil.

Product licence number 0152/5066.

SILBEPHYLLINE*

Presentation *Tablets:* White tablets marked 'BERK' with single break line on reverse. Each tablet contains 200 mg Diprophylline PhEur.

Clear ampoules: Each ampoule contains 500 mg Diprophylline PhEur in 2 ml.

White suppositories: Each contain 400 mg Diprophylline PhEur.

Red syrup: Each 5 ml contains 100 mg Diprophylline PhEur.

Uses Bronchodilator. Chronic bronchitis, bronchial asthma and congestive heart failure.

'Silbephylline' is a soluble, neutral, stable theophylline derivative. It dilates bronchiolar vessels and relaxes bronchial musculature. When injected there is direct myocardial stimulation and dilation of coronary and other circulatory vessels. 'Silbephylline' also has a mild diuretic action.

Dosage and administration *Adults: Tablets: Acute conditions:* 2 tablets every six hours.

Maintenance therapy: 1–2 tablets three times daily.

Suppositories: 2 inserted within 24 hours or one at night.

Injection: Intramuscularly: 1 ampoule two or three times daily.

Intravenously: 1 ampoule by slow administration over one to two minutes.

Syrup: Adults: Two to four 5 ml spoonfuls every six hours.

Children: Under 1 year: 0.5–1.5 ml every six hours.

1–2 years: 2 ml every six hours.

3–5 years: 3 ml every six hours.

6–12 years: 5 ml every six hours.

Dilution of syrup may be effected with Syrup Simplex.

Contra-indications, warnings, etc No known contra-indications.

Intravenous injections must be given slowly, otherwise headache, palpitation, dizziness, nausea and fall in blood pressure may occur.

Reported side-effects are few and mild. Overdosage may produce symptoms of xanthine poisoning – e.g. nausea, headache, vomiting, thirst, restlessness and shock.

Treatment of overdosage: Gastric lavage and intensive symptomatic therapy. Convulsions, acidosis, hypokalaemia and possibly cardiac dysrhythmia may require correction.

Pharmaceutical precautions No special precautions.

Diluent for ampoules: Water for Injection BP.

Diluent for syrup: Syrup BP.

ETRACHEL*

Presentation *Tablets:* Orange film-coated Tetracycline Tablets BP 250 mg engraved BERK 3C7.

Capsules: Orange Tetracycline Capsules BP 250 mg.

Syrup: Red Syrup (Tetracycline Syrup BPC) containing tetracycline equivalent to tetracycline hydrochloride 25 mg per 5 ml.

Uses Infections caused by organisms sensitive to tetracycline. These include pneumonia, acute and chronic bronchitis, whooping cough, psittacosis, urinary tract infections, amoebic dysentery, brucellosis and chlamydial fevers.

Dosage and administration *Adults:* 1 tablet or capsule or 2 teaspoonfuls syrup every six hours.

Children: $\frac{1}{2}$ –1 teaspoonful syrup every six hours according to age.

Contra-indications, warnings, etc Tetrachel is contra-indicated in patients with advanced renal insufficiency and in those hypersensitive to tetracyclines.

Administration of Tetrachel with milk, antacids, calcium or iron preparations may affect absorption.

Tetracyclines should only be administered with great caution to patients with hepatic insufficiency. Careful monitoring of dosage by serum levels is necessary.

Prolonged use of an anti-infective agent may result in the development of superinfection due to micro-organisms resistant to the anti-infective.

Tetracyclines are absorbed to some extent by developing bones and teeth and may produce staining and enamel hypoplasia. For this reason, during the second half of pregnancy, during breast feeding and in children up to the age of eight years, tetracycline should only be administered if considered essential by the physician, and for as short a treatment period as feasible. Repeated courses should be avoided. The effect appears to be

related to total dosage given and not only to duration of treatment.

Tetracyclines should only be administered with great caution to patients with renal insufficiency and dosage may need to be reduced.

Tetracyclines may prolong the action of coumarin anticoagulants, and may themselves delay coagulation.

Tetracyclines should only be used with great caution in conjunction with other potentially hepatotoxic drugs.

Cross-resistance between tetracyclines may develop in micro-organisms, and cross-sensitisation in patients.

Tetrachel should not be used in conjunction with penicillins.

Side-effects may include nausea, vomiting or diarrhoea, and glossitis, stomatitis, vaginitis or pruritus and due to candidal overgrowth. Resistant staphylococci may occasionally give rise to enterocolitis. Skin rashes and allergic reaction are rare.

Treatment of overdosage: Serious symptoms are unlikely. Gastric lavage might be beneficial in the first hours after ingestion followed by conservative management. Milk will reduce absorption.

Pharmaceutical precautions Incompatible with alkalis and chloramphenicol.

Diluent for syrup: Syrup BP.

Legal category POM.

Package quantities *Tablets:* Packs of 100 and 1,000.

Capsules: Containers of 100 and 500.

Syrup: Containers of 500 ml.

Further information Nil.

TRIMOPAN*

Presentation

Trimopan 200 mg tablet: White, circular, biconvex tablets, marked 'Berk 3H7' on one side with a single breakline on the reverse. Each tablet contains 200 mg Trimethoprim BP.

Trimopan 100 mg tablets: White, circular, biconvex tablets marked 'Berk 2H7' on one side with a single break-line on the reverse. Each tablet contains 100 mg Trimethoprim BP.

Trimopan suspension: White suspension containing 50 mg Trimethoprim BP in each 5 ml.

Uses Trimopan has potent antimicrobial activity due to its selective inhibition of bacterial dihydrofolate reductase. It is effective *in-vitro* against most Gram-positive and Gram-negative aerobic organisms, including *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Klebsiella pneumoniae*, *Staphylococcus aureus*, *E. coli*, *Enterobacter*, *Proteus* and *Streptococcus faecalis*.

Exceptions include anaerobic bacteria. *Mycobacterium tuberculosis*, *Neisseria gonorrhoeae*, *Pseudomonas aeruginosa* and *Treponema pallidum*.

Indications: Treatment of susceptible infections caused by trimethoprim-sensitive organisms including urinary tract and respiratory tract infections.

Prophylaxis of recurrent urinary tract infections.

Dosage and administration

Adults and children over 12 years of age: Treatment of urinary tract infections and all other susceptible infections: 200 mg twice daily.

Long-term prophylaxis of recurrent urinary tract infections: 100 mg at night.

Children 4 months to 12 years of age: Treatment of urinary tract infections and all other susceptible infections is based on a dosage of 6 mg/kg body weight daily subdivided into two equal doses. Suggested regimens are:

4 months–2 years	25 mg twice daily
2–6 years	50 mg twice daily
6–12 years	100 mg twice daily

Long-term prophylaxis of recurrent urinary tract infections is based on 2.5 mg/kg body weight daily given as a single dose at night. Suggested regimens are:

4 months–2 years	25 mg at night
2–8 years	50 mg at night
8–12 years	100 mg at night

Contra-indications, warnings, etc *Contra-indications:* Severe hepatic insufficiency. Severe renal insufficiency, unless blood trimethoprim concentrations can be monitored regularly.

Megaloblastic anaemia and other blood dyscrasias.

Trimethoprim should not be administered to pregnant women, premature infants or children under 4 months of age.

Precautions: In patients with marked impairment of renal function, care should be taken to avoid accumulation and resulting adverse haematological effects. Regular haematological tests should be undertaken in patients receiving long-term treatment and those predisposed to folate deficiency. Particular care should be exercised in the haematological monitoring of children on long-term therapy. The usual caution in prescribing any drug for women of childbearing age should be exercised with trimethoprim. Trimethoprim is excreted in breast milk but is not contra-indicated for short term use in lactating mothers.

Side-effects: Nausea, vomiting, gastrointestinal disturbance, headache, skin rashes and pruritus have been reported but are rare.

Isolated cases of megaloblastic anaemia during prolonged therapy with trimethoprim in doses higher than those recommended have been reported but these are reversible with discontinuation of therapy and administration of calcium folinate.

Treatment of overdosage: Symptomatic treatment, gastric lavage and forced diuresis can be used. Depression of haematopoiesis by trimethoprim can be counteracted by intramuscular administration of calcium folinate.

Pharmaceutical precautions No special precautions.

Legal category POM.

UBRETID*

Presentation *Tablets:* White tablets marked 'UBRETID' with single break line on reverse. Each tablet contains 5 mg distigmine bromide.

Ampoules: Clear ampoules each containing 0.5 mg distigmine bromide in 1 ml.

Uses Anticholinesterase. Post-operative urinary retention. Post operative ileus and intestinal atony. To assist emptying of the neurogenic bladder. As an adjuvant in the treatment of myasthenia gravis.

'Ubretid' distigmine bromide is an anticholinesterase with a much longer duration of action than neostigmine or pyridostigmine. In man, maximum inhibition of plasma cholinesterase occurs nine hours after a single intramuscular dose of 0.5 mg 'Ubretid', and persists for approximately 24 hours returning to normal after 48 hours.

Dosage and administration *In prevention of urinary retention, ileus or intestinal atony following surgery:* 1 'Ubretid' Ampoule by intramuscular injection given 12 hours after surgery is usually adequate prophylaxis and this may be repeated at 24-hourly intervals until normal function is restored. Caution should be exercised in the timing of this initial dose, where doubt exists as to the integrity of any bowel anastomosis. When injections are not convenient, 1 'Ubretid' Tablet may be given daily half-an-hour before breakfast.

In neurogenic bladder: 1 'Ubretid' Tablet daily or on alternate days, half-an-hour before breakfast, on an empty stomach. Intramuscular injections may be given in place of tablets for the first few days of therapy.

In myasthenia gravis – tablets only should be used.

Adults: Dosage to be individualised for each patient, dependent upon the severity of the condition, the degree and duration of response and the side-effects encountered. The tablets should always be taken on an empty stomach half an hour before breakfast. Dosage should commence at 1 tablet daily and may be adjusted at intervals of three to four days to a total not exceeding 4 tablets daily.

Children: Up to 2 tablets daily, according to age.

Contra-indications, warnings, etc 'Ubretid' is contra-indicated in cases of severe post-operative shock serious circulatory insufficiency and serious spastic and mechanical ileus.

'Ubretid' should not be administered to pregnant women.

'Ubretid' should be used with caution in conditions where the potentiation of acetylcholine effects is undesirable, e.g. vagotonia, bronchial asthma, cardiac disease peptic ulcer, epilepsy and Parkinsonism.

In myasthenia gravis, where short-acting cholinergic drugs are taken concurrently, their dosage should be reduced to the minimum required to control symptoms.

The patient should be supervised in the early stages of dosage regulation to guard against the possibility of myasthenic crisis or cholinergic crisis.

Overdosage with 'Ubretid' would be expected to give rise to the signs of anticholinesterase poisoning. Atropine (up to 2 mg i.m.) should be given at once and repeated at intervals indicated by the clinical progress until signs:

of mild atropinisation appear (dry mouth, mydriasis). The patient is best kept fully atropinised for 24 hours.

Muscarinic side-effects of 'Ubretid' are usually few and mild, and can be controlled with atropine, giving 2 mg intramuscularly and maintaining atropinisation for at least 24 hours.

Treatment of overdosage: Oral absorption is poor unless Ubretid is taken on a completely empty stomach. Observation may be sufficient. Generalised parasympathomimetic symptoms should be antagonised by atropine.

Pharmaceutical precautions No special precautions.

Diluent for ampoules: Water for Injection BP.

Legal category POM.

Package quantities *Tablets:* Containers of 20 and 100 tablets.

Ampoules: Boxes of 10.

Further information Nil.

VIDOPEN*

Presentation Red and pink Ampicillin Capsules BP 250 mg marked VIDOPEN 250 and 500 mg marked VIDOPEN 500.

Pink powder for Syrup 125 mg/5 ml (Ampicillin Mixture BPC), or Syrup Forte 250 mg/5 ml (strong Ampicillin Mixture BPC), wild cherry flavoured and containing ampicillin trihydrate equivalent to the stated quantities of ampicillin.

Uses Ampicillin is a broad-spectrum antibiotic active against *Shigella*, *Escherichia coli*, *Proteus mirabilis*, *Haemophilus influenzae*, *Bordetella pertussis* and other Gram-negative bacteria. *Actinomyces muris ratti* and other Actinomycetes, as well as penicillin-sensitive Gram-positive pathogens. Vidopen is therefore indicated in a wide range of infections, particularly those of the respiratory, urinary and digestive tracts where there may be multiple pathogens.

Vidopen is not effective against organisms resistant to penicillin, since it is inactivated by penicillinase.

Dosage and administration Vidopen should be taken half an hour before meals.

Adults: ENT infections: 250 mg four times daily.

Bronchitis: 250 mg four times daily, or up to 1 g four times daily in acute exacerbations.

Pneumonia: 500 mg four times daily.

Urinary tract infections: 500 mg three times daily.

Gastro-intestinal infections: 500–750 mg three or four times daily.

Children: Over 20 kg bodyweight: Adult dosage.

Under 20 kg bodyweight:

Moderately severe infections: 100 mg/kg/day in divided doses every six or eight hours.

Severe infections: 200 mg/kg/day in divided doses every six hours.

Contra-indications, warnings, etc Known sensitivity to penicillin or the cephalosporins is a contra-indication. Patients should be questioned on this before Vidopen is prescribed.

Safety in pregnancy has not been established.

A rash may occur, particularly in patients with infectious mononucleosis. If it does, Vidopen should be discontinued.

Gastro-intestinal symptoms may occur but usually resolve rapidly when treatment is stopped. If they persist they may indicate overgrowth of resistant organisms, requiring specific treatment.

Ampicillin is inactivated by penicillinase and should therefore not be used to treat infections which have survived treatment with penicillin.

Treatment of overdosage: Serious symptoms are unlikely. Observation.

Pharmaceutical precautions Store in a cool dry place.

The suspension, when made up, should be stored in a cool place and used within seven days. It may be diluted with Syrup BP.

Legal category POM.

Package quantities *Capsules 250 mg:* Containers of 250 and 1,000.

Capsules 500 mg: Containers of 100 and 500.

Syrup: Bottles of 100 mg.

Syrup Forte: Bottles of 100 ml.

Further information Nil.

VITA-E* (BIOGLAN*) GELUCAPS*
VITA-E* (BIOGLAN*) GELS
VITA-E* SUCCINATE (BIOGLAN)
VITA-E* (BIOGLAN*) OINTMENT

Presentation *Vita-E Gelucaps 75 i.u.*: Yellow oval coated tablets, 14.5 mm diameter, each containing d- α -tocopheryl acetate equivalent to 75 i.u. vitamin E.

Vita-E Gels 75 i.u.: Yellow oval soft gelatin capsules 11 mm diameter, each containing d- α -tocopheryl acetate equivalent to 75 i.u. vitamin E.

200 i.u.: Yellow oblong soft gelatin capsules, 16.5 mm diameter, marked 'BLE 200', each containing d- α -tocopheryl acetate equivalent to 200 i.u. vitamin E.

400 i.u.: Red oblong soft gelatin capsules, 19 mm diameter, marked 'BLE 400', each containing d- α -tocopheryl acetate equivalent to 400 i.u. vitamin E.

Vita-E Ointment 30 i.u./g: Yellow soft paraffin BP each gram containing d- α -tocopheryl acetate equivalent to 30 i.u. vitamin E.

Vita-E Succinate tablets 200 i.u.: Yellow circular scored tablets. Engraved 'BIOGLAN' on one side and '200 I.U.E.' on other, each containing d- α -tocopheryl acid succinate equivalent to 200 i.u. of vitamin E.

Uses *Indications*: Intermittent claudication, and as a prophylactic against cardiovascular degeneration.

Vita-E preparations provide a powerful anti-oxidant for a variety of diseases, all of which have one thing in common – a local decrease in oxygen supply.

The ointment is indicated for burns, pressure sores, external ulcers and wounds.

Dosage and administration *Vita-E Gelucaps*: Oral – chewed and eaten during meals.

Vita-E Gels: swallowed intact and taken with meals.

Vita-E Succinate tablets: Oral – taken with meals.

Vita-E Ointment: Application to affected area.

Intermittent claudication: 600–1,600 i.u. daily.

Cardiovascular degeneration: 75–400 i.u. daily.

The doses recommended are larger than nutritional studies would demand, but smaller dosage is generally

insufficient for successful therapy. The maintenance dose equals the therapeutic dose.

Vitamin E is not recommended for self-medication since as a therapeutic agent and when used with other medications, d'alpha tocopherol may enhance/lessen the effect of those medications. A physician should be consulted.

Contra-indications, warnings, etc Fish-liver oils should not be given at the same time, as they appear to have a detrimental effect on the vitamin. If iron is indicated, separate the doses by about nine hours.

The digitalis requirement is often reduced with vitamin E therapy, and full digitilisation is often achieved by what is ordinarily a maintenance digitalis dose. Insulin dosages in diabetic cardiacs must be watched closely for the insulin requirement may be considerably reduced very suddenly.

Hyperthyroidism is usually contra-indicated.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities *Vita-E Gelucaps (75 i.u.)* are available in containers of 100.

Vita-E Gels (75 i.u., 200 i.u. and 400 i.u.) are available in containers of 100 and 500 Gels.

Vita-E Succinate tablets (200 i.u.) are available in containers of 100 and 500.

Vita-E Ointment 30 i.u./g available in 50 g double-wall ointment jars.

Further information Wounds and burns heal more rapidly with an absolute minimum of scar formation when Vita-E Ointment (30 i.u./g) is used in conjunction with Vita-E by mouth.

ALUPENT®

Presentation *Alupent Tablets*: White/off white compressed tablets, scored and impressed with the letters 'At' on one side and with the Company symbol on the reverse. Each tablet contains orciprenaline sulphate 20 mg.

Alupent Syrup: Clear, colourless syrup with vanilla-like flavour. Each 5 ml contains orciprenaline sulphate 10 mg.

Alupent Metered Aerosol: 15 ml vial (300 metered doses) available as complete unit with mouthpiece or as refill vial only. Each metered dose contains orciprenaline sulphate 0.75 mg (0.67 mg available to the patient).

Alupent Inhalant Solution: Clear, colourless stabilised solution of orciprenaline sulphate 5%.

Alupent Ampoules: Ampoules for injection. Each ampoule contains orciprenaline sulphate 0.5 mg in 1 ml.

Uses *Action*: Alupent is a sympathomimetic amine with bronchodilator properties.

Indications: Alupent is indicated for the relief of bronchospasm, as in asthma, bronchitis and emphysema.

Alupent Tablets and Syrup are suggested for maintenance therapy.

Alupent Metered Aerosol and Inhalant Solution are indicated for the relief of acute attacks. Alupent ampoules are for maintenance therapy in patients unable to take other dosage forms. On occasions the ampoules have been used for treatment of acute attacks.

Dosage and administration *Orally*

	<i>Tablets 20 mg</i>	<i>Syrup 10 mg in 5 ml</i>
<i>Adults</i>	1 four times daily	2 × 5 ml four times daily
<i>Children 3-12 years</i>	½ four times daily to 1 three times daily	1 × 5 ml four times daily to 2 × 5 ml three times daily
<i>Children 1-3 years</i>	Syrup recommended	½ × 5 ml four times daily to 1 × 5 ml four times daily
<i>Children 0-1 year</i>	Syrup recommended	½ × 5 ml three times daily to 1 × 5 ml three times daily

By inhalation: Individual response may vary, and the appropriate dose for any patient is best decided by the attending doctor. The recommendations below provide general guidelines.

Metered Aerosol 0.75 mg per puff (0.67 mg available to the patient):

Adults: 1 or 2 puffs. Not to be repeated within 30 minutes. No more than 12 puffs in 24 hours.

Children 6-12 years: 1 or 2 puffs. Not to be repeated within 30 minutes. No more than 4 doses in 24 hours.

Children under 6 years: 1 puff. Not to be repeated within 30 minutes. No more than 4 puffs in 24 hours.

Inhalant Solution 5%: The dose recommended for use in a gas driven nebulizer (eg Bennett, Bird) is:

Adults: 0.2 ml of Alupent 5% Solution (equivalent to 10 mg orciprenaline sulphate) diluted with sterile sodium chloride 0.9% solution or sterile distilled water to 2 ml, and inhaled completely.

Children (under 8 years): 0.1 ml of Alupent 5% solution (equivalent to 5 mg orciprenaline sulphate) diluted with sterile sodium chloride 0.9% solution or sterile distilled water to 2 ml and inhaled completely.

For other nebuliser systems, the dilution may be adjusted for the recommended volumes.

The inhalant solution should not be allowed to come into prolonged contact with metallic components. Thus, when a nebuliser is not in use the reservoir should be emptied and a fresh solution used at each session.

By intra-muscular injection:

	<i>Adults</i>	<i>Children 6-12 years</i>	<i>Children under 6 years</i>
<i>Ampoules 0.5 mg in 1 ml</i>	1 ampoule repeated after 30 minutes if necessary	1 ampoule	½ ampoule

Diluents: Alupent Syrup may be diluted with either Syrup BP or Sorbitol Solution BPC. Alupent inhalant solution may be freshly diluted with either sterile sodium chloride 0.9% solution or sterile distilled water.

Contra-indications, warnings, etc

Contra-indications: Thyrotoxicosis.

Precautions: Caution should be observed should it be necessary to administer Alupent to patients with myocardial insufficiency, angina, cardiac dysrhythmias, hypertension or hypertrophic subvalvular aortic stenosis. In view of the possible interaction between sympathomimetic amines and monoamine oxidase inhibitors, care should be exercised if it is proposed to administer an MAO inhibitor concurrently with Alupent. Caution should be observed with the use of Alupent if a patient is already receiving other sympathomimetic agents as cardiovascular effects may be additive.

Patients must be instructed in the correct use of a metered aerosol, and warned not to exceed the prescribed dose. Patients should also be warned to seek medical advice if a reduced response becomes apparent.

Although Alupent has been in wide general use for many years, there is no definite evidence of ill-consequence during human pregnancy. Only in doses much higher than the equivalent maximum therapeutic dose in man were effects on foetal development seen in animals. Alupent treatment may result in the prolongation of pregnancy and inhibition of labour. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Beta-adrenergic blocking agents may antagonise Alupent and reduce its bronchodilator effect if administered concurrently.

Side-effects: Transitory sympathomimetic side-effects, such as tremor, palpitation, tachycardia and headache, have occasionally been reported, as have nausea and abdominal discomfort.

Overdosage: A fatal dose has not been reported but the following single doses should be considered toxic – 1.5 mg by IV injection, 3.0 mg by IM or SC injection, 0.15 mg/min by IV infusion, 200 mg orally.

Overdosage may be manifest by tachycardia, palpitation, increase in systolic blood pressure, decrease in diastolic blood pressure, tremor and anxiety. It is suggested that the patient should be treated symptomatically, but care should be taken if beta-adrenergic blocking drugs are used in patients liable to bronchospasm.

Pharmaceutical precautions Alupent preparations should be protected from heat, light and air. Aerosol vials should not be incinerated or opened.

Legal category POM.

Package quantities *Tablets:* Packs of 50, 250 and 1,000

Syrup: Packs of 250 ml and 2 litres.

Metered Aerosol: 15 ml vial (300 metered doses) complete with mouthpiece. 15 ml refill vial.

Inhalant Solution: 10 ml.

Ampoules: Packs of 6.

Further information Nil.

ALUPENT* EXPECTORANT

Presentation *Alupent Expectorant Tablets:* White/off white compressed tablets, scored and impressed with the letters $\frac{AtB}{\overline{817}}$ on one side, and with the Company symbol on the reverse. Each tablet contains orciprenaline sulphate 20 mg and bromhexine hydrochloride 8 mg.

Alupent Expectorant Mixture: Colourless, clear liquid. Each 5 ml contains orciprenaline sulphate 10 mg and bromhexine hydrochloride 4 mg.

Uses *Action:* Alupent Expectorant provides the dual action of the bronchodilator Alupent (orciprenaline sulphate) and the mucolytic agent Bisolvon (bromhexine hydrochloride).

Alupent is a sympathomimetic amine with bronchodilator properties. Bisolvon stimulates the mucous glands to produce a secretion which is less viscous and has a reduced content of acid glycoprotein fibres.

Indications: Alupent Expectorant is indicated for conditions in which both bronchospasm and sputum are present, e.g. in asthma or bronchitis. During infective episodes a suitable antibiotic should also be given.

Dosage and administration

Orally

	Adults	Children 5–10 years	Children under 5 years
<i>Tablets</i>	1 four times daily	$\frac{1}{2}$ three or four times daily	Mixture recommended
<i>Mixture</i>	2 × 5 ml four times daily	1 × 5 ml three or four times daily	1 × 5 ml twice daily

Diluent: Alupent Expectorant Mixture may be diluted with Syrup BP or with Sorbitol Solution BPC.

Contra-indications, warnings, etc

Contra-indications: Thyrotoxicosis.

Precautions: Caution should be observed should it be necessary to administer Alupent Expectorant to patients with myocardial insufficiency, angina, cardiac dysrhythmias, hypertension or hypertrophic subvalvular aortic stenosis. In view of the possible interaction between sympathomimetic amines and monoamine oxidase inhibitors, care should be exercised if it is proposed to administer an MAO inhibitor concurrently with Alupent, one of the constituents of Alupent Expectorant.

In patients with gastric ulceration relative caution should be observed in the use of Bisolvon, one of the constituents of Alupent Expectorant.

Although Alupent Expectorant has been in wide general use for many years, there is no definite evidence of ill-consequence during human pregnancy. Only in doses much higher than the equivalent maximum therapeutic dose in man were effects on foetal development seen in animals. Alupent Expectorant treatment may result in the prolongation of pregnancy and inhibition of labour. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Beta-adrenergic blocking agents may antagonise Alupent and reduce its bronchodilator effect if administered concurrently.

Side-effects: Transitory sympathomimetic side-effects, such as tremor, palpitation, tachycardia and headache, have occasionally been reported with Alupent, as have nausea and abdominal discomfort.

Occasional gastro-intestinal side-effects may be caused by Bisolvon, but these are almost invariably mild. In a very few patients a transitory rise in serum transaminase levels may be seen during treatment with Bisolvon. With continuation of the drug transaminases return to pre-treatment levels, even in those patients in whom there was pre-existing impairment of hepatic function.

Overdosage: Orciprenaline may cause tachycardia, palpitation, increase in systolic blood pressure, decrease in diastolic blood pressure, tremor and anxiety. These should be treated symptomatically, but care should be taken if beta-adrenergic blocking agents are used in patients liable to bronchospasm. Toxic effects following overdosage with bromhexine have not been reported, but animal studies suggest that these may include listlessness, anorexia, ataxia, cyanosis, pulmonary rales, hypothermia, diuresis, respiratory failure, convulsions or coma.

Pharmaceutical precautions Alupent Expectorant Tablets and Mixture should be protected from heat, light and air.

Legal category POM.

Package quantities *Tablets:* 50 and 250.

Mixture: 250 ml and 2 litres.

Further information Nil.

Alupent Expectorant Mixture	0015/0025

ATROVENT®

Presentation *Metered dose inhaler:* 10 ml vial (200 metered doses) available as complete unit with mouthpiece. Each metered dose contains ipratropium bromide 0.02 mg of which 0.018 mg is available to the patient.

Nebuliser solution: an aqueous solution of ipratropium bromide 0.025% (0.25 mg/ml) for administration by inhalation.

Uses *Action:* Atrovent is an anticholinergic drug with bronchodilator properties.

Indications: Atrovent metered dose inhaler is indicated in the treatment of chronic reversible airways obstruction, particularly in chronic bronchitis.

Atrovent nebuliser solution is indicated in the treatment of reversible airways obstruction.

Dosage and administration *Metered dose inhaler:* *Adults:* Usually 1 or 2 puffs three or four times daily, although some patients may need up to 4 puffs at a time to obtain maximum benefit during early treatment.

Children: 6–12 years: usually 1 or 2 puffs three times daily. Under 6 years: usually 1 puff three times daily.

In order to ensure that the inhaler is used correctly, administration should be supervised by an adult.

Nebuliser solution: Atrovent nebuliser solution may be administered from an intermittent positive pressure ventilator or from suitable nebulisers.

The recommended dose per inhalation ranges from 0.1–0.5 mg and this can be achieved by nebulising 0.4–2.0 ml solution. These volumes may be suitably measured using the integral dropper (20 drops are approximately equivalent to 1 ml) and diluted with sterile sodium chloride 0.9% solution or sterile distilled water for ease of administration.

Adults: 0.1–0.5 mg up to 4 times daily. Single doses of 2.0 mg have been safely given.

Children: (3–14 years) 0.1–0.5 mg up to 3 times daily. Single doses of 1.0 mg have been safely given.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to atropine.

Precautions: Patients must be instructed in the correct use of a metered dose inhaler or nebuliser solution and warned against the accidental release of the contents into the eye. Generally, caution is advocated in the use of anticholinergic agents in patients with glaucoma and prostatic hypertrophy. However, specific studies with Atrovent in patients with glaucoma showed that inhaling cumulative doses of 0.16 mg had no effect on the eye.

Atrovent has been in general use for several years and there is no definite evidence of ill-consequence during pregnancy; animal studies have shown no hazard. Nevertheless, medicines should not be used in pregnancy, especially during the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

If a reduced response to Atrovent becomes apparent, the patient should seek medical advice.

Side-effects: Anticholinergic side-effects are unlikely at therapeutic doses, but some patients may complain of a dry mouth. Urinary retention and constipation have only rarely been reported with Atrovent. There is no evidence that in the therapeutic dose range Atrovent has any adverse effect on bronchial secretion.

Overdosage: Inhaled doses of 5.0 mg produce an increase in heart rate and palpitation. Single doses of

ipratropium bromide 30 mg by mouth cause anti-cholinergic side-effects but these are not severe and do not require specific reversal.

Pharmaceutical precautions *Atrovent metered dose inhaler:* Protect from heat including the sun. The vials should not be punctured or incinerated even when empty.

Atrovent nebuliser solution: Store at room temperature. Protect from heat and light. Once the bottle has been opened, the contents should not be kept for longer than 1 month. Following dilution, Atrovent nebuliser solution should be used within 24 hours.

Legal category POM.**Package quantities**

Atrovent metered dose inhaler: 10 ml vial (200 metered doses) complete with mouthpiece.

Atrovent nebuliser solution: 20 ml in amber glass bottle complete with integral dropper.

Further information There is evidence that the concurrent administration of Atrovent and sympathomimetic drugs produces a greater relief of bronchospasm than either drug given alone.

Atrovent has been shown to produce effective bronchodilation in patients receiving beta-adrenergic blocking agents.

Atrovent nebuliser solution	0015/0078

BISOLVOMYCIN®

Presentation Turquoise blue/grey capsules imprinted with the Company symbol. Each capsule contains bromhexine hydrochloride 8 mg and oxytetracycline hydrochloride 250 mg.

Uses *Action:* Bisolvomycin provides the dual action of the mucolytic agent Bisolvon (bromhexine hydrochloride) and the bacteriostatic antibiotic oxytetracycline hydrochloride.

Bisolvon stimulates the mucous glands to produce a secretion which is less viscous and has a reduced content of acid glycoprotein fibres.

Oxytetracycline is effective against a wide range of both Gram-positive and Gram-negative organisms.

Indications: Those conditions of the upper or lower respiratory tract associated with the retention of viscid mucoid secretions and complicated by the presence of tetracycline-sensitive organisms, e.g. bronchitis, infective asthma, bronchiectasis, sinusitis. Other treatment for bronchospasm should be given as appropriate.

Dosage and administration *Adults and children over 12 years:* 1 capsule four times daily. *Children under 12 years:* oxytetracycline is not recommended as it may cause staining of teeth.

Contra-indications, warnings, etc

Contra-indications: As oxytetracycline is one of the active constituents, Bisolvomycin should not be given in pregnancy or in the presence of renal or hepatic dysfunction. The concurrent administration of antacids should be avoided.

Precautions: Caution should be observed in patients with gastric ulcer.

Side-effects: Bisolvon may cause occasional gastro-intestinal side-effects, but these are almost invariably mild. In a very few patients a transient rise in serum transaminase levels has been seen with Bisolvon. With continued treatment transaminases usually return to pretreatment levels, even in those patients in whom there was pre-existing hepatic dysfunction.

Nausea, diarrhoea and symptoms from the overgrowth of resistant organisms have been reported with oxytetracycline.

Overdosage: Toxic effects following overdosage with bromhexine have never been reported, but animal studies suggest that these might include listlessness, anorexia, ataxia, cyanosis, pulmonary rales, hypothermia, diuresis, respiratory failure, convulsions or coma.

Animal studies suggest that toxic effects following overdosage with oxytetracycline may include gastro-intestinal irritation, anorexia, epigastric burning, nausea, vomiting, diarrhoea, headache and symptoms of raised intracranial pressure, jaundice and azotaemia. Management should be symptomatic with appropriate treatment for liver or renal failure if present.

Pharmaceutical precautions Bisolvomycin Capsules should be protected from air, light and moisture.

Legal category POM.

Package quantities Packs of 20 and 250.

Further information Nil.

Product licence number 0015/5003.

BISOLVON*

Presentation *Bisolvon Tablets:* Yellow, compressed tablets, impressed with the letter B on one side and with the Company symbol on the reverse. Each tablet contains bromhexine hydrochloride 8 mg.

Bisolvon Elixir: Clear, yellow liquid. Each 5 ml contains bromhexine hydrochloride 4 mg.

Bisolvon Ampoules: Ampoules for injection. Each ampoule contains bromhexine hydrochloride 4 mg in 2 ml.

Uses *Action:* Bisolvon is a mucolytic expectorant whose action is to stimulate the mucous glands to produce a secretion which is less viscous and has a reduced content of acid glycoprotein fibres.

Indications: Those conditions of the upper and lower respiratory tract associated with retention of viscid mucoid secretions, e.g. bronchitis, asthma, bronchiectasis, sinusitis. Other treatment for infection or bronchospasm should be given as appropriate.

Dosage and administration *Orally:*

	Adults	Children 5-10 years	Children under 5 years
<i>Tablets</i> 8 mg	1 three times daily to 2 four times daily	$\frac{1}{2}$ four times daily	$\frac{1}{2}$ twice daily
<i>Elixir 4 mg</i> <i>in 5 ml</i>	2 x 5 ml three times daily to 4 x 5 ml four times daily	1 x 5 ml four times daily	1 x 5 ml twice daily

By injection: Adults only, not generally recommended for children under 12 years.

Ampoules 4 mg in 2 ml: 2-6 ampoules daily. The ampoules should be given by slow intravenous or deep intramuscular injection. Alternatively 1-5 ampoules may be added to 250-500 ml of 5% dextrose solution or 1-10

ampoules to 250-500 ml of sodium chloride 0.9% solution and given by slow intravenous infusion.

Diluents: Bisolvon Elixir may be diluted with either water or Sorbitol Solution BPC.

Contra-indications, warnings, etc

Contra-indications: There are no absolute contra-indications to the use of Bisolvon.

Precautions: In patients with gastric ulceration caution should be observed with the use of Bisolvon.

Although Bisolvon has been in wide general use for many years, there is no evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: Occasional gastro-intestinal side-effects may be caused, but these are almost invariably mild. In a very few patients a transitory rise in serum transaminase levels may be seen during treatment with Bisolvon. With continuation of the drug, transaminases return to pretreatment levels, even in those patients in whom there was pre-existing impairment of hepatic function.

Overdosage: Toxic effects following overdosage have never been reported, but animal studies suggest that these might include listlessness, anorexia, ataxia, cyanosis, pulmonary rales, hypothermia, diuresis, respiratory failure, convulsions or coma. These should be treated symptomatically.

Pharmaceutical precautions Bisolvon Tablets, Elixir and Ampoules should be protected from light and heat.

Bisolvon Ampoules 0015/5004

BUSCOPAN*

Presentation *Buscopan Tablets:* White, sugar-coated tablets, printed on one side with the Company symbol. Each tablet contains hyoscine-N-butylbromide 10 mg.

Buscopan Ampoules: Ampoules for intramuscular or intravenous injection, each containing hyoscine-N-butylbromide 20 mg in 1 ml.

Uses *Action:* Buscopan is an antispasmodic agent, which relaxes smooth muscle of the organs of the abdominal and pelvic cavities. It is believed to act predominantly on the intramural parasympathetic ganglia of these organs.

Indications: Buscopan Tablets are indicated in spasm of the gastro-intestinal tract or the genito-urinary tract, and in spasmodic dysmenorrhoea.

Buscopan Ampoules are indicated in acute spasm, as in renal or biliary colic; in radiology for differential diagnosis of obstruction and to reduce spasm and pain in pyelography, and in other diagnostic procedures where spasm may be a problem, e.g. gastro-duodenal endoscopy.

Dosage and administration *Adults: Orally:* 2 tablets four times daily. In spasmodic dysmenorrhoea, treatment should commence two days before the expected onset of the period and continue for three days after menstruation has begun.

By injection: 1 ampoule intramuscularly or intravenously repeated after half-an-hour if necessary. When used in endoscopy this dose may need to be repeated more frequently.

Children 6–12 years: Orally: 1 tablet three times daily.

Diluent: Buscopan Injection Solution may be diluted with dextrose or with sodium chloride 0.9% injection solutions. It is also miscible and compatible with most of the commonly used aqueous radiological contrast media such as diodone, sodium acetate and sodium diatrizoate.

Contra-indications, warnings, etc

Contra-indications: Because of a possible mydriatic effect, Buscopan should not be administered to patients with glaucoma.

Precautions: Although Buscopan has been in wide general use for many years, there is no definite evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: Dryness of the mouth, temporary loss of accommodation and tachycardia have very occasionally been reported.

Overdosage: Oral doses of up to 1090 mg produced only tiredness. Other features which may be encountered are dry mouth, loss of accommodation, tachycardia, orthostatic hypotension and Cheyne-Stokes respiration.

Gastric lavage should be employed where appropriate. Parasympathetic agents, e.g. pilocarpine or neostigmine, should be used as necessary.

Pharmaceutical precautions Buscopan Tablets and Ampoules should be protected from light and heat.

Legal category POM.

Package quantities *Tablets:* Packs of 100 and 500.

Ampoules: Packs of 10.

Further information Nil.

Buscopan Ampoules 0015/5005

CATAPRES®

Presentation *Catapres Tablets 0.10 mg:* White compressed tablets impressed with the motif  on one side and with the Company symbol on the reverse. Each tablet contains clonidine hydrochloride 0.10 mg.

Catapres Tablets 0.30 mg: White, compressed tablets impressed with the motif  and with the Company symbol on the reverse. Each tablet contains clonidine hydrochloride 0.30 mg.

Catapres PL Perlongets: red/yellow gelatin capsules imprinted with the notation Catapres PL, 11P and the Company symbol. Each Perlonget contains 5 mini-

tablets constituting 0.25 mg clonidine hydrochloride in sustained release form.

Catapres Ampoules: Ampoules for injection. Each ampoule contains clonidine hydrochloride 0.15 mg in 1 ml.

Uses **Action:** Catapres has been shown to have both central and peripheral sites of action. With long-term treatment Catapres reduces the responsiveness of peripheral vessels to vasoconstrictor and vasodilator substances and to sympathetic nerve stimulation. Early in treatment, however, blood pressure reduction is associated with a central reduction of sympathetic outflow and increased vagal tone.

Clinically there may be reduced venous return and slight bradycardia resulting in reduced cardiac output. Although initially peripheral resistance may be unchanged it tends to be reduced as treatment continues. There is no interference with myocardial contractility. Studies have shown that cardiovascular reflexes, as shown by the lack of postural hypotension and exercise hypotension, are preserved.

Indications: Catapres is indicated for the treatment of all grades of essential and secondary hypertension, hypertension during pregnancy and hypertensive crises.

Catapres PL is indicated for all degrees of hypertension excluding hypertensive crises.

Dosage and administration *Catapres Tablets:* Oral treatment should commence with 0.05–0.10 mg three times daily.

This dose should be increased gradually every second or third day until control is achieved. Most patients will be controlled on divided daily doses of 0.30–1.2 mg. However, some patients may require higher doses, e.g. 1.8 mg or more.

Catapres PL Perlongets: most patients will be satisfactorily controlled on one Perlonget daily (usually given in the evening). This dosage can be increased if necessary up to 2 or 3 Perlongets daily (one in the morning and one or two at night).

Catapres may be added to an existing antihypertensive regimen where blood pressure control has not been satisfactorily achieved. If side-effects with existing therapy are troublesome the concomitant use of Catapres may allow a lower dose of the established regimen to be employed. Patients changing treatment should have their existing therapy reduced gradually whilst Catapres is added to their regimen.

Catapres Ampoules: In hypertensive crises 1 or 2 Catapres Ampoules should be given by slow intravenous injection.

An effect is usually seen within 10 minutes and reaches a maximum about 30 minutes to 1 hour after administration. The duration of effect depends upon the severity of the condition and is commonly of the order of 3–7 hours. Up to 5 ampoules may be given in 24 hours to achieve and maintain the desired blood pressure.

Patients undergoing anaesthesia should continue their Catapres treatment before, during and after anaesthesia, using oral or intravenous administration according to individual circumstances.

Diluent: Catapres Injection Solution is compatible with 0.9% sodium chloride solution and with 5% dextrose solution.

Contra-indications, warnings, etc

Contra-indications: There are no known absolute contra-indications to the use of Catapres.

Precautions: This product may cause drowsiness. Pa-

tients who are affected should not drive or operate machinery. Sedation due to the drug may be increased by the concomitant use of other central nervous depressants.

Sudden withdrawal of Catapres, particularly in those patients receiving high doses, may result in rebound hypertension. Termination of long-term therapy with Catapres for any reason should therefore be performed gradually. With Catapres PL this may be achieved by progressively increasing the interval between doses. If a hypertensive episode should nevertheless occur, reintroduction of oral or intravenous Catapres should reverse any such effect. If the use of Catapres is not practical then an alpha-adrenergic blocking drug, such as phentolamine, should be used.

Patients with a known history of depression should be carefully supervised while under long-term treatment with Catapres as there have been occasional reports of further depressive episodes during oral treatment in such patients.

Caution should be exercised in patients with Raynaud's disease or other occlusive peripheral vascular disease. As with all drugs used in hypertension, Catapres should be used with caution in patients with cerebrovascular, coronary or renal insufficiency.

Concomitant use of diuretics or other antihypertensive agents will usually result in an increased hypotensive effect.

Concomitant administration of tricyclic anti-depressants may reduce the hypotensive effect of Catapres.

Alpha-adrenergic blocking drugs antagonise the acute effects of Catapres.

Although clonidine has been in wide general use for many years, there is no definite evidence of hazard during human pregnancy. In animal studies involving doses higher than the equivalent maximum therapeutic dose in man, effects on foetal development were seen only in one species. Foetal malformations did not occur. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Catapres should only be given to breast-feeding women if considered essential by the physician. There is as yet insufficient experience to enable Catapres to be recommended for children.

Intravenous injection of Catapres should be given slowly to avoid a possible transient pressor effect. This is particularly important in patients already under treatment with other hypotensive agents such as guanethidine or reserpine.

Side-effects: Initially, sedation or dry mouth are encountered in a few patients. These effects usually subside as treatment continues. Other drug-related side-effects which have been mentioned in the literature include dizziness, headache, nocturnal unrest, nausea, euphoria, constipation, impotence (rarely) and agitation on withdrawal of long-term therapy.

There are occasional reports of fluid retention during initial stages of oral treatment. This is usually transitory and can be corrected by the addition of a diuretic.

Facial pallor has been noted following injection.

A single case of toxic hepatitis has been reported, but the authors commented that the role of Catapres in hepatotoxicity in this patient remains questionable.

Acute administration in animals or in man has occasionally induced a transient elevation of blood sugar. This is believed to be due to the initial pharmacological effect of alpha-adrenergic stimulation. Investigators

agree that this has no clinical significance. The inclusion of diabetic patients in many Catapres investigations has confirmed its suitability as an antihypertensive agent for such patients.

Overdosage: Accidental overdosage may cause hypotension, bradycardia, sedation and coma. Transient hypertension may be seen if the total dose is over 10 mg.

Gastric lavage should be performed where appropriate. In most cases all that is required are general supportive measures. Forced diuresis has been employed. Where bradycardia is severe atropine will increase the heart rate. If hypotension is giving rise to concern the administration of an alpha-adrenergic blocking drug such as phentolamine may help.

Pharmaceutical precautions Catapres Tablets and Ampoules should be protected from light and heat.

Legal category POM.

Package quantities Tablets 0.10 mg: Packs of 50 and 250.

Tablets 0.30 mg: Pack of 100.

Perlongets 0.25 mg: Pack of 56.

Ampoules 0.15 mg in 1 ml: Pack of 5.

Further information No adverse reaction has been reported with the concurrent administration of digoxin, aminophylline, anticonvulsants or antiarrhythmic preparations. Monitoring of haematological and hepatic status in large numbers of patients has revealed no drug-related adverse effects. Renal blood flow and glomerular filtration rates are maintained and there is no deterioration in renal function. There is evidence that plasma renin levels are reduced. Catapres does not affect the estimation of VMA levels.

Clonidine hydrochloride is also available as Dixarit 0.025 mg tablets (WB Pharmaceuticals Ltd) for the prophylactic management of migraine, recurrent vascular headache and menopausal flushing.

DULCODOS*

Presentation White, sugar-enteric-coated tablets printed on one side with the Company symbol. Each tablet contains bisacodyl (Dulcolax*) 5 mg and docusate sodium 100 mg.

Uses Action: Dulcodos combines the contact laxative effect of Dulcolax with the faecal softening action of docusate sodium. Dulcodos Tablets disintegrate in the small intestine, the two constituents being released simultaneously. In the colon, docusate sodium, by lowering surface tension, allows water to penetrate the faecal mass more readily, preventing normal faeces from becoming inspissated. At the same time Dulcolax on contact with the mucosa of the large bowel, initiates a general peristaltic movement which results in the evacuation of soft, well-formed stools. Neither substance depends for its effect on systemic absorption. Dulcodos Tablets, when taken after food, act in 10-12 hours.

Indications: Chronic constipation, or other conditions in which painful defaecation is a problem. Replacement of

the enema, prior to surgery, labour or radiological investigation, in conjunction with Dulcolax Suppositories.

Dosage and administration Dulcodos Tablets are suitable for routine use in adults, and children over 10 years.

In constipation, 2 tablets at night.

For complete bowel clearance, 2 tablets at night, followed by one Dulcolax Suppository next morning.

In radiology, 2 tablets on each of the two nights prior to the investigation, followed by 1 Dulcolax Suppository (if necessary) 1 hour before the investigation.

Contra-indications, warnings, etc

Contra-indications: Only those conditions where any laxative is contra-indicated.

Precautions: Because Dulcodos Tablets are enteric-coated for disintegration in the intestine, they should not be crushed or chewed. For the same reason antacids should not be given within 1 hour of administering Dulcodos Tablets.

Although Dulcodos has been in general use for many years, there is no evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: The mode of action of Dulcolax, and the addition of the faecal softener, docusate sodium, mean that side-effects, such as abdominal discomfort, should only rarely be encountered.

Overdosage: Colicky lower abdominal pain with possible signs of dehydration may be expected particularly in the elderly and the very young.

Gastric lavage should be performed where appropriate. Adequate hydration must be maintained and the serum potassium should be measured. Antispasmodics may be of some value. Particular care about fluid balance should be taken in the elderly and young.

Pharmaceutical precautions Dulcodos Tablets should be protected from heat and light.

Legal category P.

Package quantities Blister packs of 20 and 100.

Further information Nil.

Product licence number 0015/5013.

DULCOLAX®

Presentation *Dulcolax Tablets:* Yellow sugar-enteric-coated tablets printed on one side with the Company symbol. Each tablet contains bisacodyl 5 mg.

Dulcolax Suppositories: White, opaque, foil-wrapped suppositories, each containing bisacodyl 10 mg.

Dulcolax Children's Suppositories: White, opaque, foil-wrapped suppositories for children each containing bisacodyl 5 mg.

Dulcolax Rectal Solution: Buffered polyethylene glycol solution containing bisacodyl 2.74 mg/ml.

Uses **Action:** Dulcolax is a synthetic laxative which acts on contact with the mucosa of the large bowel. It is reliable and predictable in its action, producing in most cases a soft, formed stool without straining.

Dulcolax Tablets taken after food act in 10–12 hours.

A Dulcolax Suppository will produce a motion within 20 minutes to 1 hour of insertion.

Indications: Constipation, either chronic or of recent onset, whenever a stimulant laxative is required.

Bowel clearance before surgery, labour or radiological investigation. Replacement of the evacuant enema in all its indications.

The rectal solution is indicated specifically in radiological procedures, either as a preparatory measure when given as a miniature enema to reduce flatus and faecal shadow interference, or mixed with the barium enema.

Dosage and administration Dulcolax is suitable for routine use in adults of all ages, and in children.

1. In constipation

(a) *Adults and children over 10 years:* 2 tablets at night, or one 10 mg suppository in the morning. (Occasionally a higher tablet dosage is required: up to 3 or 4 may be given.)

(b) *Children under 10 years:* 1 tablet at night or one 5 mg suppository in the morning.

2. For replacement of the enema

(a) *Adults and children over 10 years:* 2 tablets at night followed by one 10 mg suppository in the morning.

(b) *Children under 10 years:* 1 tablet at night followed by one 5 mg suppository in the morning.

3. In preparation for radiological investigation

(a) *Adults and children over 10 years:* 2 tablets on each of the 2 nights before the investigation and one 10 mg suppository (if necessary) 1 hour before investigation. Where needed 2–3 ml of the rectal solution may be administered, as a miniature enema.

(b) *Children under 10 years:* 1 tablet on each of the 2 nights before the investigation and one 5 mg suppository (if necessary) 1 hour before the investigation. Where needed 1–2 ml of the rectal solution may be administered, as a miniature enema.

N.B. Dulcolax Rectal Solution may be administered together with a barium enema, at a dose of 2–5 ml in 1–3 litres of enema solution.

Contra-indications, warnings, etc

Contra-indications: Only those conditions where any laxative is contra-indicated.

Precautions: Because Dulcolax Tablets are enteric-coated for disintegration in the intestine, they should not be crushed or chewed. For the same reason, antacids should not be given within 1 hour of administering Dulcolax Tablets.

Dulcolax Solution is for rectal administration only.

Although Dulcolax has been in general use for many years, there is no evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Nevertheless, medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: As with any effective laxative, griping has occasionally been reported after administration of Dulcolax Tablets. If this occurs, it can be minimised by dosage adjustment.

Overdosage: Colicky lower abdominal pain with possible signs of dehydration may be expected particularly in the elderly and the very young.

Gastric lavage should be performed where appropriate. Adequate hydration must be maintained and the serum potassium should be measured. Antispasmodics may be

of some value. Particular care about fluid balance should be taken in the elderly and young.

Pharmaceutical precautions All dosage forms should be protected from heat and light.

Legal category P.

Package quantities *Tablets*: Packs of 40, 200 and 1,000.

Suppositories 10 mg: Packs of 6, 50 and 200.

Children's Suppositories 5 mg: Packs of 6.

Rectal Solution: 250 ml bottles.

Further information Nil.

MEXITIL*

Presentation *Mexitil Capsules 200 mg*: red/red hard gelatin capsules imprinted with the notation 200 mg and the Company symbol. Each capsule contains mexiletine hydrochloride 200 mg.

Mexitil Capsules 50 mg: red/purple hard gelatin capsules imprinted with the notation 50 mg and the Company symbol. Each capsule contains mexiletine hydrochloride 50 mg.

Mexitil Ampoules: Ampoules for intravenous injection. Each ampoule contains mexiletine hydrochloride 250 mg in 10 ml.

Uses *Action*: Mexitil is an anti-arrhythmic agent which depresses the maximum rate of depolarisation with little or no modification of resting potentials or the duration of action potentials.

Indications: For the treatment of existing or anticipated ventricular arrhythmias and ectopic beats such as those found after myocardial infarction and in ischaemic heart disease. Also for ventricular arrhythmias induced by digitalis or other drugs and for idiopathic and other ventricular arrhythmic states. It has been given in conjunction with, or after, other anti-arrhythmic preparations and also other drugs acting on the cardiovascular system.

Dosage and administration

1. Intravenous Mexitil:

- (a) *Loading dose*: IV injection of 4–10 ml (100–250 mg) Mexitil given at a suggested rate of 1 ml per minute (25 mg per minute).

Then

add 500 mg (2 ampoules) Mexitil to 500 ml of a suitable infusion solution (see 'Pharmaceutical Precautions'). Administer the first 250 ml by IV infusion over 1 hour (4 ml per minute).

Then

administer the second 250 ml by IV infusion over 2 hours (2 ml per minute).

- (b) *Maintenance dose*: Add 250 mg (1 ampoule) Mexitil to 500 ml of a suitable infusion solution (see 'Pharmaceutical Precautions'). Administer by IV infusion at a suggested rate of 1 ml per minute (0.5 mg per minute), according to patient response. Continue for as long as required or until oral maintenance therapy is commenced.

2. Oral Mexitil

- (a) *Loading dose*: Give 400 mg Mexitil.
(b) *Maintenance dose*: Give 200–250 mg Mexitil three to four times daily commencing 2 hours after the loading dose. The usual daily dose is between 600–800 mg in divided doses.

Note: In acute myocardial infarction and particularly when opiates have been given, absorption may be delayed and therefore a larger loading dose e.g. 600 mg may be preferable.

3. Alternative loading dose regimes

- (a) *Combination IV Mexitil and Oral Mexitil loading dose*: IV injection of 8 ml (200 mg) Mexitil given at a suggested rate of 1 ml per minute. On completion of injection or infusion give 400 mg Mexitil orally.
Maintenance dose.
As in 2b.
(b) *Combination IV Lignocaine and Oral Mexitil loading dose*: Give IV lignocaine according to manufacturer's instructions.
On completion of injection give 400 mg Mexitil orally.
Maintenance dose.
As in 2b.

4. *Change over from IV to Oral Mexitil maintenance*: On discontinuing the IV infusion commence the maintenance dose. Give 200–250 mg Mexitil orally three or four times a day.

Notes:

1. The loading dose regime is designed to compensate for the rapid phase of tissue distribution which occurs especially with IV loading.

2. Side-effects are more likely to be encountered during the initial tissue loading phase in which case the rate of infusion should be reduced.

3. If the optimum therapeutic effect is not achieved the rate of infusion or oral dosage may be increased, side-effects permitting.

4. Gastric emptying time may be delayed in patients with myocardial infarction and/or to whom opiates have been given and thus it may be necessary to titrate the dose against therapeutic effects and side-effects.

5. The 50 mg capsule is available in order that a more precise dose titration may be undertaken should this be required. Smaller increments will also reduce the incidence of side-effects.

Contra-indications, warnings, etc

Contra-indications: In view of the conditions in which ventricular arrhythmias may be encountered there are no specific exclusions or contra-indications. However, if the drug is used in the following situations, the patient should be carefully monitored: sinus node dysfunction, conduction defect, bradycardia, hypotension or cardiac, renal or hepatic failure. There may be potentiation of tremor in patients with Parkinsonism.

Precautions: Because of the conditions in which Mexitil is used, patients will usually be under observation with particular regard to ECG and blood pressure. Routine laboratory monitoring is also advisable although disturbance of renal and hepatic function or appearance of anti-nuclear factor have not been a feature even of long-term treatment.

The duration of treatment required in any patient is of necessity variable, and although no precise guide can be given, withdrawal of treatment may be attempted after

a suitable period free of arrhythmia. Gradual withdrawal, i.e. over 1–2 weeks, is preferable as arrhythmias which have been satisfactorily controlled may recur.

Although Mexilit has been in general use for several years, there is no definite evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: Side-effects are mainly related to blood concentration and may therefore be seen during the initial phases of both IV and oral treatment when fluctuation may occur before the blood and tissue concentrations reach equilibrium. Reducing the rate of injection or infusion or delaying the next oral dose allows the blood concentration to fall and usually reduces side-effects. Generally side-effects are of three types:

Gastro-intestinal – nausea, vomiting, indigestion, unpleasant taste, hiccoughs.

Central nervous system – light-headedness, drowsiness, confusion, dizziness, diplopia, blurred vision, nystagmus, dysarthria, ataxia, tremor, paraesthesiae, convulsion.

Cardiovascular – hypotension, sinus bradycardia, atrial fibrillation, palpitation.

Side-effects can usually be reversed by reducing dosage. When hypotension has occurred this has tended to be in patients with severe illness who have already been given a variety of anti-arrhythmic or other preparations and, if associated with bradycardia, may be reversed by the use of atropine. Animal studies using toxic doses have shown that benzodiazepines (diazepam) reduce the CNS effects.

Overdosage: The minimum fatal dose is unknown but 4.40 g proved fatal in a healthy young adult.

The clinical features include nausea, vomiting, drowsiness, confusion, ataxia and convulsions. Blurred vision and paraesthesiae have also been reported. Hypotension, sinus bradycardia, atrial fibrillation and cardiac arrest are more specific effects.

Gastric lavage should be performed where appropriate and the patient should be transferred to an intensive/coronary care unit for possible cardiopulmonary support. Arrhythmias should be treated as appropriate and diazepam may be useful to control convulsions.

Pharmaceutical precautions Mexilit solution for injection is known to be compatible with the following infusion solutions: sodium chloride 0.9%; sodium chloride 0.9% with potassium chloride 0.3% or 0.6%; dextrose 5%; sodium bicarbonate 1.4%; sodium lactate (M/6).

Legal category POM.

Package quantities

Capsules 200 mg: pack of 100.

Capsules 50 mg: pack of 100.

Ampoules 250 mg in 10 ml: pack of 5.

Further information Mexilit has been used successfully within a few hours of myocardial infarction. Concomitant IV therapy with other local anaesthetic type anti-arrhythmic agents such as lignocaine or procainamide is not recommended, although no problems have been encountered using oral mexiletine in conjunction with these drugs. Mexilit may be used concurrently with digoxin and beta-adrenergic blocking drugs.

Mexilit Ampoules 250 mg in 10 ml 0015/0065

PERSANTIN®

Presentation A white sugar-coated tablet with the Company symbol on one side, containing dipyridamole 100 mg.

Uses Action: Dipyridamole has an antithrombotic action based on its ability to modify various aspects of platelet function, such as platelet aggregation, adhesion and survival, which have been shown to be factors associated with the initiation of thrombus formation.

Dipyridamole modifies platelet function by enhancing prostacyclin effect through a strong inhibition of phosphodiesterase and mild stimulation of adenylyl cyclase formation. It has also been shown to inhibit the formation of thromboxane A₂ which is known to cause platelet adhesion and aggregation.

Indications: For diseases or conditions where modification of platelet function may be beneficial.

Dosage and administration Adults: Three to six tablets (300–600 mg) daily in three or four doses.

Children: The normal total daily dose is 5 mg/kg in divided doses.

Persantin should usually be taken before meals.

Contra-indications, warnings, etc

Contra-indications: There are no absolute contra-indications to the administration of Persantin.

Precautions: Persantin is a potent vasodilator and should therefore be used with caution in patients with rapidly worsening angina, sub-valvular aortic stenosis or haemodynamic instability associated with a recently sustained myocardial infarction.

Although Persantin has been in wide general use for many years there is no evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: If these occur it is usually during the early part of treatment and they are often dose-related. The vasodilating properties of Persantin may occasionally produce a vascular headache which normally disappears with dosage reduction. Dyspepsia has occasionally been reported. Mild diarrhoea is rarely encountered.

Overdosage: Overdosage may lead to headache, gastro-intestinal symptoms and hypotension. Coronary vasodilation may cause chest pain in patients with ischaemic heart disease.

General supportive measures should be employed. Coronary vasodilation may be reversed by administering aminophylline by slow IV injection.

Pharmaceutical precautions Protect from heat, light and moisture.

Legal category POM.

Package quantities Packs of 100 tablets.

Further information There is evidence that the effects of aspirin and dipyridamole on platelet behaviour are synergistic. Persantin is also licensed as a coronary vasodilator in the form of 25 mg tablets and 10 mg/2 ml

ampoules for slow intravenous injection. The 25 mg tablets may be used where dose titration is required for the modification of platelet function in children.

Product licence number 0015/5016.

TRANXENE*

Presentation Pink/grey hard gelatin capsules imprinted with the notation 15 mg and the Company symbol. Each capsule contains potassium clorazepate 15 mg.

Uses *Action:* Tranxene is a tranquilliser exhibiting many characteristics of the benzodiazepine group of preparations. Particular features which distinguish Tranxene from other members of this group are the rapid appearance in the blood of the anxiolytic compound nordiazepam, the maintenance of satisfactory therapeutic effect with once daily administration and little sedation.

Indications: Relief of all forms of anxiety, tension and agitation in acute and chronic anxiety states. Tranxene is compatible with all antidepressants in the treatment of anxiety accompanied by depression.

Dosage and administration Adults only, not generally recommended for children under 12 years. 1 capsule daily, usually administered at night.

Contra-indications, warnings, etc

Contra-indications: There are no absolute contra-indications to the use of Tranxene.

Precautions: As sole treatment, Tranxene is not recommended for acute primary depressive states or major psychoses.

The action of Tranxene may potentiate other preparations with central nervous system depressant effects such as barbiturates, narcotics, phenothiazines and alcohol.

Although sedation has not proved to be a problem with Tranxene, in accordance with general principles patients should be advised that their ability to drive or to operate dangerous machinery may be impaired.

Although Tranxene has been in wide general use for many years, there is no definite evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Tranxene and its metabolites are excreted in human milk in minimal quantities.

Side-effects: Side-effects which have been reported only rarely are dizziness, gastro-intestinal upset, nervousness, blurred vision, dry mouth, headache and mental confusion. Drowsiness has occasionally been reported but does not constitute a major problem.

Overdosage: An overdose of 900 mg (60 capsules) has been reported causing drowsiness, ataxia, respiratory depression and coma. Treatment should include gastric lavage and/or induced vomiting and general supportive therapy.

Pharmaceutical precautions Tranxene Capsules should be protected from heat, light and moisture.

Legal category POM.

Package quantities Packs of 100 in aluminium foil strips.

Further information In common with other benzodiazepines Tranxene has a central muscle-relaxant effect, and synergism with peripherally acting muscle relaxants is a theoretical possibility.

Product licence number 0015/0057.

VILLESCON* LIQUID

Presentation Red, raspberry-flavoured liquid. Each 5 ml contains:

Prolintane hydrochloride	2.5 mg
Thiamine hydrochloride	1.67 mg
Riboflavin-5-phosphate sodium	1.36 mg
Pyridoxine hydrochloride	0.5 mg
Nicotinamide	5.0 mg

Uses *Action:* The principal ingredient of Villescon, prolintane hydrochloride, is a sympathomimetic amine with two main actions. It stimulates appetite and has a mild central action which produces an increased feeling of well-being in debilitated patients.

Indications: Villescon is indicated as a tonic after illness, surgery or labour, for apathy and anorexia in elderly patients, for institutional neuroses and for anorexia and lassitude following radiotherapy.

Dosage and administration *Adults:* 2 × 5 ml twice daily.

Children 5–12 years: $\frac{1}{2}$ × 5 ml twice daily to 2 × 5 ml twice daily.

The normal course of treatment is from 1–2 weeks.

It is recommended that the second daily dose be taken before four o'clock in the afternoon.

Diluent: Villescon Liquid may be diluted with purified water.

Contra-indications, warnings, etc

Contra-indications: Thyrotoxicosis, epilepsy.

Precautions: Although no interaction between Villescon and MAO inhibitors has ever been demonstrated, the theoretical possibility of such an interaction should be borne in mind if these preparations are co-prescribed. It should be noted that even in very small quantities pyridoxine hydrochloride (vitamin B₆) inhibits the activity of levodopa.

There exists a proportion of patients whose ill-defined symptoms reflect a basic inadequacy of personality. Such patients are liable to misuse any drug with central activity, and it is advised that in these cases the recurrent prescription of Villescon should be avoided.

Although Villescon Liquid has been in wide general use for many years, there is no definite evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: Tachycardia, nausea and colicky abdominal pains have been reported. Sleeplessness may be caused if Villescon is taken late in the day.

Overdosage: Accidental overdosage has been reported only rarely and may give rise to restlessness, insomnia, tachycardia and increase of blood pressure. An overdose of 300 mg prolintane has been reported in a young female who made a full recovery. Treatment should include gastric lavage and general supportive measures. Sedation may be required to treat restlessness and insomnia.

Pharmaceutical precautions Villescon preparations should be protected from heat, light and moisture.

Legal category POM.

Package quantities Bottles of 250 ml and 1 litre.

Further information Nil.

Product licence number 0015/0054.

VILLESCON* TABLETS

Presentation Orange, sugar-coated tablets, with the Company symbol on one side. Each tablet contains:

Prolintane hydrochloride	10.0 mg
Thiamine mononitrate	5.0 mg
Riboflavin	3.0 mg
Pyridoxine hydrochloride	1.5 mg
Nicotinamide	15.0 mg
Ascorbic acid	50.0 mg

Uses Action: The principal ingredient of Villescon, prolintane hydrochloride, is a sympathomimetic amine with two main actions. It stimulates appetite and has a mild central action which produces an increased feeling of well-being in debilitated patients.

Indications: Villescon is indicated as a tonic after illness, surgery or labour, for apathy and anorexia in elderly patients, for institutional neuroses and for anorexia and lassitude following radiotherapy.

Dosage and administration *Adults:* 1 tablet twice daily.

Children over 8 years: 1 tablet after breakfast.

The normal course of treatment is from 1–2 weeks. It is recommended that the second daily dose be taken before four o'clock in the afternoon.

Contra-indications, warnings, etc

Contra-indications: Thyrotoxicosis, epilepsy.

Precautions: Although no interaction between Villescon and MAO inhibitors has ever been demonstrated, the

theoretical possibility of such an interaction should be borne in mind if these preparations are co-prescribed. It should be noted that even in very small quantities pyridoxine hydrochloride (vitamin B₆) inhibits the activity of levodopa.

There exists a proportion of patients whose ill-defined symptoms reflect a basic inadequacy of personality. Such patients are liable to misuse any drug with central activity, and it is advised that in these cases the recurrent prescription of Villescon should be avoided.

Although Villescon Tablets have been in wide general use for many years there is no definite evidence of ill-consequence during human pregnancy; animal studies have shown no hazard. Medicines should not be used in pregnancy, especially the first trimester, unless the expected benefit is thought to outweigh any possible risk to the foetus.

Side-effects: Tachycardia, nausea and colicky abdominal pains have been reported. Sleeplessness may be caused if Villescon is taken late in the day.

Overdosage: Accidental overdosage has been reported only rarely and may give rise to restlessness, insomnia, tachycardia and increase of blood pressure. An overdose of 300 mg prolintane has been reported in a young female who made a full recovery. Treatment should include gastric lavage and general supportive measures. Sedation may be required to treat restlessness and insomnia.

Pharmaceutical precautions Villescon preparations should be protected from heat, light and moisture.

Legal category POM.

Package quantities Packs of 20 and 100.

Further information Nil.

Product licence number 0015/0055.

* Trade Mark

The Boots Company PLC

1 Thane Road West
Nottingham NG2 3AA

ABICOL*

Presentation Abicol is presented as pink, scored tablets, each containing Reserpine BP 0.15 mg and Bendrofluzide BP 2.5 mg.

Uses Abicol is indicated for all grades of hypertension, either alone or in conjunction with other hypotensive agents.

Dosage and administration For most cases of hypertension, half to one tablet morning and evening. If necessary, dosage may be increased up to two tablets morning and evening. When Abicol is added to an existing regimen of antihypertensive drugs, the dosage of the latter should be reduced initially.

Contra-indications, warnings, etc

Electrolyte imbalance: All the thiazide diuretics can produce some degree of electrolyte imbalance, especially in patients with renal or hepatic impairment, or when dosage is high or prolonged. Serum electrolyte levels should be checked for abnormalities, particularly hypokalaemia, this being corrected by the addition of a potassium supplement to the regimen.

Digitalis intoxication: Sensitivity to digitalis may be increased by the kaliuretic effect of concurrent bendrofluzide and patients should be observed for signs of digitalis intoxication. Should these appear, the dosage of digitalis should be reduced temporarily and a potassium supplement given to restore stability.

Uric acid retention: Thiazide diuretics may raise serum uric acid levels with consequent exacerbation of gout in susceptible subjects.

Diabetes: Thiazide derivatives sometimes lower carbohydrate tolerance and it may be necessary to adjust the insulin dosage of the diabetic patient. Care is also necessary when bendrofluzide is administered to those with a known pre-disposition to diabetes.

Pregnancy: Thiazides cross the placental barrier and it is, therefore, reasonable to assume that side-effects occurring in the adult may also develop in the foetus.

Other side-effects which may be encountered are those associated with reserpine, i.e. lethargy, vertigo, tremor, gastro-intestinal upset and nasal congestion.

Treatment of overdosage: Symptomatic and supportive; there is no specific antidote.

Pharmaceutical precautions Recommended storage conditions: 5°C to 20°C.

Legal category POM.

Package quantities Containers of 100 and 500 tablets.

Further information Bendrofluzide is an oral diuretic and antihypertensive agent which augments the antihypertensive activity of reserpine, thus allowing a smaller dose of the latter to be used. In this way, the side-effects

associated with the normal therapeutic dose of reserpine are less likely to occur or are reduced in severity.

Product licence number 0014/5126.

APRINOX*

Presentation Aprinox is Bendrofluzide BP, an oral diuretic of the benzothiadiazine group. Aprinox is available as white tablets in two strengths, 2.5 mg and 5 mg.

Uses Aprinox is indicated in all cases where the reduction of fluid retention by diuresis is required – oedema of cardiac, renal or hepatic origin; premenstrual, iatrogenic and all other types of oedema.

Aprinox will produce a moderate but usefully prolonged fall of blood pressure in hypertensive patients and often gives adequate control when used alone; if necessary, Aprinox can be administered concurrently with other specific hypotensive agents, allowing a reduction in the dosage of the latter.

Aprinox will effectively inhibit lactation without the hormonal effects attendant upon stilboestrol or other oestrogens.

Dosage and administration *Diuretic:* Initially 5–10 mg once daily or on alternative days. Maintenance: 5–10 mg once or twice weekly. The dose should be taken early in the morning so as to complete diuresis by bedtime.

Hypotensive: 2.5–5 mg once daily. When Aprinox is used concurrently with other specific hypotensive agents the dose of the latter should be halved.

A suggested dosage for inhibition of lactation is 5 mg in the morning and 5 mg at midday for about five days.

Dosage in children should be at the discretion of the attending physician.

Contra-indications, warnings, etc **Electrolyte imbalance:** All the thiazide diuretics can produce a degree of electrolyte imbalance, especially in patients with renal or hepatic impairment, or when dosage is high or prolonged. Serum electrolyte levels should be checked for abnormalities, particularly hypokalaemia, and the latter corrected by the addition of a potassium supplement to the regimen.

Note: Aprinox does not contain a potassium supplement.

Digitalis intoxication: Sensitivity to digitalis may be increased by the kaliuretic effect of concurrent bendrofluzide. Patients should be observed for signs of digitalis intoxication; if these appear, the dosage of digitalis should be temporarily reduced and a potassium supplement given to restore stability.

Uric acid retention: The thiazide diuretics may raise serum uric acid levels with consequent exacerbation of gout in susceptible subjects.

Diabetes: Thiazide derivatives sometimes lower carbohydrate tolerance and the insulin dosage of the diabetic patient may require adjustment. Care is necessary when bendroflumazide is administered to those with a known predisposition to diabetes.

Pregnancy: Thiazides cross the placental barrier; therefore it is reasonable to assume that side-effects occurring in the adult may also appear in the neonate.

Pharmaceutical precautions Recommended storage conditions: 5–20°C.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information A single dose of Aprinox will induce a diuresis extending over 12–18 hours – a period which can be contained within the patient's normal working day, leaving the night undisturbed. Simple dosage schedules, a low incidence of side-effects and economy in prescribing have established Aprinox as one of the most useful general-purpose diuretics.

Product licence numbers

Aprinox 2.5 mg 0014/5117

Aprinox 5 mg 0014/5118

BRUFEN®

Presentation Brufen is available as Brufen 400, sugar-coated tablets each containing 400 mg of Ibuprofen BP. The tablets are light-magenta in colour and bear the overprint 'Brufen 400' in black.

Brufen is available also as sugar-coated tablets each containing 200 mg of Ibuprofen BP. These are also light-magenta in colour and are overprinted 'Brufen' in black.

For children, and for adults who have difficulty in swallowing tablets, Brufen is presented as Brufen Syrup, an orange flavoured liquid containing 100 mg of Ibuprofen BP in each 5 ml.

Uses Brufen is indicated for its analgesic and anti-inflammatory effect in the treatment of rheumatoid arthritis (including juvenile rheumatoid arthritis or Still's disease) ankylosing spondylitis, osteoarthritis and other non-rheumatoid (seronegative) arthropathies.

In the treatment of non-articular rheumatic conditions, Brufen is indicated in periarticular conditions such as frozen shoulder (capsulitis), bursitis, tendinitis, tenosynovitis and low-back pain; Brufen can also be used in soft-tissue injuries such as sprains and strains.

Brufen is also indicated for its analgesic effect in the relief of mild to moderate pain such as dysmenorrhoea, dental and post-operative pain.

Dosage and administration *Adult:* The recommended dosage of Brufen is 1,200 mg daily in divided doses. Some patients can be maintained on 600–1,200 mg daily.

In severe conditions it can be advantageous to increase the dosage to 1,600 mg daily in divided doses until the acute phase is brought under control.

For the relief of mild to moderate pain the following dosages are recommended:

Dysmenorrhoea: 1,200 mg per day in three divided doses

Analgesia 1,200 to 1,600 mg daily given in divided doses

In cases of dental or post-operative pain an initial dose of 400 mg may be given.

The total daily dose of Brufen should not exceed 2,400 mg.

Children: The dosage of Brufen is 20 mg per kg of body weight daily except that in children weighing less than 30 kg the total dose given in 24 hours should not exceed 500 mg.

Contra-indications, warnings, etc Brufen should not be given to patients with severe or active peptic ulceration. Whilst no teratogenic effects have been demonstrated in animal experiments, the use of Brufen during pregnancy should, if possible, be avoided. Brufen should be prescribed with caution for those with asthma and especially for patients who have developed bronchospasm with other nonsteroidal agents.

Adverse effects reported include dyspepsia, gastrointestinal intolerance and bleeding, and skin rashes of various types. Less frequently, thrombocytopenia has occurred. Toxic amblyopia has occurred very rarely but, in those cases reported, recovery occurred on cessation of treatment.

Treatment of overdosage: Gastric lavage and, if necessary, correction of blood electrolytes. There is no specific antidote to Brufen.

Pharmaceutical precautions Brufen Syrup should be stored below 25°C.

Legal category POM.

Package quantities *Brufen 400 (400 mg tablets):* Pack of 100, pack of 250.

Brufen Tablets (200 mg): Pack of 100, pack of 500.

Brufen Syrup: Bottle of 200 ml.

Further information Taken on an empty stomach, peak serum levels of Brufen occur 45 minutes after ingestion, whereas, taken after a meal, the peak is delayed up to 90 minutes. Since most people can take Brufen on an empty stomach without gastric discomfort, the initial dose of the day will be more rapidly effective if taken before food. This is particularly valuable in providing relief of the morning stiffness associated with arthritis.

Brufen Syrup 0014/0217

CHLORPROPAMIDE – BOOTS

Presentation Chlorpropamide – Boots is available as white, scored tablets each containing either 100 mg (7 mm diameter) or 250 mg (9.5 mm diameter) of Chlorpropamide BP.

Uses Chlorpropamide is indicated for the treatment of mild or moderately severe uncomplicated diabetes mellitus of the stable, non-ketotic, maturity-onset or adult type. It should not be used to replace dietetic therapy in the obese diabetic patient.

Dosage and administration Generally, chlorpropamide should be given as a single dose each morning before breakfast. The initial dose is 250–500 mg daily and this should be reduced to a maintenance level as soon as possible. In elderly patients, a smaller dose is advisable.

In establishing the optimal dosage for a particular patient, it should be borne in mind that it may take four to seven days for the hypoglycaemic response to become

maximal. It may take several weeks to achieve adequate control.

Note: The daily dosage of chlorpropamide should not exceed 500 mg.

Contra-indications, warnings, etc Chlorpropamide is contra-indicated in juvenile diabetes mellitus and in unstable or severely 'brittle' type diabetes; in maturity-onset type diabetes when complicated by ketosis, fever, trauma, gangrene, or by serious impairment of renal, hepatic or thyroid function. It is also contra-indicated in pregnancy.

Caution: Chlorpropamide may cause hypoglycaemic reactions, which should be treated similarly to those occurring during insulin therapy. The hypoglycaemic effects of chlorpropamide are enhanced by dicoumarol, monoamine oxidase inhibitors, beta-blockers and salicylates; conversely, the action may be diminished by adrenalin, corticosteroids, oral contraceptives and thiazide diuretics. Alcohol should be avoided since it may cause a disulfiram-like reaction.

Side-effects: These include skin sensitisation, gastro-intestinal disturbance, paraesthesias, tinnitus and headache. A rare reaction to chlorpropamide is impairment of liver function. Isolated cases of bone-marrow aplasia, including aplastic anaemia and agranulocytosis have been reported.

Treatment of overdosage: Hypoglycaemia should be treated by infusion of dextrose; treatment may have to be prolonged.

Pharmaceutical precautions None.

Legal category POM.

Package quantities 100 mg Tablets: Bottle of 500.
250 mg Tablets: Bottle of 500.

250 mg Tablets 0014/0176

CORTISTAB*

Presentation Cortistab is available as tablets and as an injection. The tablets are Cortisone Tablets BP, containing Cortisone Acetate BP, 5 mg and 25 mg; the injection is Cortisone Injection BP containing Cortisone Acetate Injection BP 25 mg per ml.

Uses Cortisone Acetate has both glucocorticoid and mineralocorticoid properties and is used mainly for replacement therapy in chronic adrenocortical insufficiency. It can be used for other conditions requiring corticosteroid therapy.

Dosage and administration As with other corticosteroids, the dosage of Cortistab should be adjusted according to the severity, prognosis and anticipated duration of the disease, and the response of the individual patient.

In replacement therapy, the normal daily requirement is 12.5–50 mg of cortisone acetate by mouth in divided doses increased during infectious trauma or stress. In other conditions, a suggested regimen is 100 to 300 mg daily by intramuscular injection or 25 to 75 mg four times daily by mouth. When the desired degree of response has been achieved, reduce the dosage *gradually* to the lowest dose which maintains remission, usually from 25 mg to 100 mg daily. In chronic conditions, it is often better to maintain a sub-optimal response with small

doses than to give high doses and produce signs of hormonal excess. After prolonged corticosteroid treatment, the function of the patient's own adrenal cortices is often suppressed. To allow normal adrenal function to be restored, Cortistab dosage should be reduced gradually, e.g. by 5 to 12.5 mg every few days. Cortisone acetate is ineffective when injected into joint capsules.

Contra-indications, warnings, etc The contra-indications to Cortistab therapy are those common to all forms of corticosteroid therapy. These include severe infections (unless there is adequate chemotherapy), peptic ulcer, osteoporosis, a history of recent psychotic illness and chronic renal insufficiency.

Caution is necessary in patients with diabetes mellitus, congestive heart failure or hypertension. During treatment, the patient should be observed for psychotic reactions, muscular weakness, electrocardiographic changes, hypertension and untoward hormonal effects.

Side-effects: Corticosteroids exert hormonal and metabolic effects and prolonged treatment may be attended by such side-effects as moonface, hirsutism, psychosis and gastro-intestinal disturbance.

Treatment of overdosage: Treatment is symptomatic but is unlikely to be required.

Pharmaceutical precautions Cortistab Tablets should be protected from light. Cortistab injection should be kept at a temperature not exceeding 25°C, it should not be allowed to freeze. Protect from light.

Legal category POM.

Package quantities Cortistab Tablets 5 mg: Bottle of 100. Cortistab Tablets 25 mg: Bottle of 100. Cortistab Injection: Ampoule of 10 ml.

Further information Nil.

Cortistab Injection: 0014/5408.

DELTASTAB* INJECTION

Presentation Deltastab Injection is a sterile suspension of 25 mg per ml of Prednisolone Acetate BP 1963.

Uses Deltastab Injection is intended primarily for the local treatment by intra-articular or peri-articular injection of arthritic conditions such as rheumatoid arthritis and osteoarthritis when few joints are involved, and in traumatic arthritis, except when associated with fractures into the joint. In addition to articular use, Deltastab Injection injected into inflamed tendon sheaths and bursae will provide symptomatic treatment.

Deltastab Injection is suitable for parenteral administration by the intramuscular route in conditions requiring systemic corticosteroids.

Dosage and administration For articular use, 5 to 25 mg depending upon the size of the joint; the injection may be repeated when relapse occurs. Not more than three joints should be treated in any one day.

For parenteral use by intramuscular injection, the dosage of Deltastab Injection will depend upon the clinical circumstances and the judgement of the physician.

Suggested dosage: 25 to 100 mg once or twice weekly

Contra-indications, warnings, etc Intra-articular and peri-articular injections of Deltastab Injection are

contra-indicated when the joint or surrounding tissues are infected. The presence of infection also precludes injection into tendon sheaths and bursae. Deltastab Injection must not be injected directly into tendons, nor should it be injected into the spinal joints or any other than true diarthrodial joints.

Precautions: It should be borne in mind that joints and tissues injected with corticosteroids have an increased susceptibility to infection and full aseptic precautions should be observed when making local injections of Deltastab.

Side-effects: With intra-articular and other local injections, the principal side-effect encountered is a temporary local exacerbation with increased pain and swelling. Normally, this subsides after a few hours. Particularly after high or prolonged local administration corticosteroids can be absorbed in amounts sufficient to produce systemic effects.

Note: When being given by intramuscular injection, the precautions, side-effects, contra-indications and withdrawal symptoms associated with the systemic use of corticosteroids become relevant to Deltastab Injection.

Treatment of overdosage: Treatment is symptomatic, but is unlikely to be required.

Pharmaceutical precautions Store between 15°C to 20°C. Protect from light. Shake well before use.

Legal category POM.

Package quantities Vial of 5 ml.

Further information Nil.

Product licence number 0014/5137.

DIALAFLEX* SOLUTIONS 61, 62, 63

Presentation Dialaflex Solutions 61, 62 and 63 are sterile solutions specially formulated for peritoneal dialysis and are available in transparent, collapsible plastic containers of 1 litre.

The formulae of the solutions are as follows:

	<i>Dialaflex 61 g/litre</i>	<i>Dialaflex 62 g/litre</i>	<i>Dialaflex 63 g/litre</i>
Dextrose BP	13.6	63.6	13.6
Sodium Lactate	5.0	5.0	5.0
Sodium Chloride BP	5.6	5.6	5.0
Calcium Chloride BP	0.26	0.26	0.26
Magnesium Chloride for Dialysis BP	0.15	0.15	0.15
Sodium Metabisulphite (antioxidant)	0.05	0.05	0.05

The following table gives the solutions in terms of mEq/litre and mmol/litre:

	<i>mEq/litre</i>	<i>g/litre</i>	<i>mmol/litre</i>
Dialaflex 61			
Sodium	140.92		140
Calcium	3.6		1.8
Magnesium	1.5		0.75
Total Chloride	100.8		100
Lactate	44.6		45
Dextrose		13.6	75
Total			364.37

Dialaflex 62		
Sodium	140.92	140
Calcium	3.6	1.8
Magnesium	1.5	0.75
Total Chloride	100.8	100
Lactate	44.6	45
Dextrose		353

Total		642.91
-------	--	--------

Dialaflex 63		
Sodium	130.52	130
Calcium	3.6	1.8
Magnesium	1.5	0.75
Total Chloride	90.5	90
Lactate	44.6	45
Dextrose		75

Total		343.67
-------	--	--------

Dialaflex Solutions are colourless.

Indications Dialaflex Solutions are indicated only for use in peritoneal dialysis. This is employed as an alternative to haemodialysis in: Acute renal failure, chronic renal failure, prolonged post-operative anuria, intractable oedema, chronic congestive heart failure, poisoning due to ingestion of dialysable poisons.

Dialaflex 61 Solution is slightly hypertonic to avoid the dangers of increased hydration by absorption of water from the peritoneal cavity. It is indicated for routine dialyses which are not intended to remove excessive fluid from the body. Dialaflex 62 Solution is markedly hypertonic and is indicated when rapid removal of oedematous fluid is indicated. Dialaflex 63 Solution has a lower sodium content than Dialaflex 61. It is indicated for use in maintenance dialysis where removal of sodium is often desirable.

Dosage and administration Administration of Dialaflex Solutions necessitates the use of a special giving set to allow delivery of the solutions to and from the peritoneal cavity. This is done through a peritoneal catheter which is generally advised to be inserted in the mid-line between the umbilicus and the symphysis pubis at the junction of the middle and lower thirds.

Adults: For each dialysis 2 litres of Dialaflex Solution, ready warmed to body temperature, should be allowed to flow into the peritoneal cavity. After 20 minutes the solution is syphoned out and the procedure is repeated as often as is warranted by the situation and the condition of the patient.

Children: Each dialysis is usually performed with a volume of 1 litre of Dialaflex Solution.

Contra-indications, warnings, etc

Contra-indications: Peritoneal dialysis should not be employed if there has been recent injury to abdominal organs or in the presence of severe peritonitis.

Precautions: If full aseptic precautions are observed the danger of infection during peritoneal dialysis is slight. However, additional precautions against this possibility may be achieved by addition of antibiotics to the dialysis solution or by parenteral antibiotic administration.

Introduction of the trocar to enable the insertion of the catheter may carry the rare possibility of intestinal perforation.

Protein loss has been reported following prolonged period of peritoneal dialysis.

In patients with normal or depleted plasma potassium levels oral potassium supplements should be given or four millimoles potassium added to each litre of Dialaflex Solution.

Side-effects: Selection of the most suitable Dialaflex Solution and proper supervision of the peritoneal dialysis should ensure no untoward effects occur.

Overdosage: As peritoneal dialysis is invariably performed under supervision the question of overdosage is unlikely to arise.

Pharmaceutical precautions *Storage:* Dialaflex Solutions should be stored at 2°C–25°C. The shelf-life is two years.

Legal category POM.

Package quantities Plastic containers of 1 litre of Dialaflex Solutions are available in packs of 10.

Further information The volume of fluid recovered after dialysis should usually exceed the volume administered. The latter can be calculated by weighing the bags before and after dialysis. The weight per ml of solution is 1.009 g for Dialaflex 61 and Dialaflex 63, and 1.028 g for Dialaflex 62. Any deficiency in fluid balance may be corrected by either the oral or intravenous routes.

62 0014/0199
63 0014/0200

DIMERCAPROL INJECTION

Presentation Dimercaprol Injection BP (B.A.L. Injection) is a sterile solution of dimercaprol in arachis oil containing 10% V/V benzyl benzoate. It is presented in 2 ml ampoules, and each ml of the injection contains 50 mg of Dimercaprol BP.

Uses Dimercaprol Injection is indicated in the treatment of acute poisoning by certain heavy metals – arsenic, mercury, gold, bismuth, thallium and antimony. Although dimercaprol has not been successful in the treatment of lead poisoning when used alone, there is evidence that, used in conjunction with sodium calciumedetate, it can be used successfully in the treatment of lead poisoning, particularly in children.

Dosage and administration By intramuscular injection:

Adults: 400 to 800 mg, in divided doses, on the first day.
200 to 400 mg, in divided doses, on second and third days.
100 to 200 mg, in divided doses, on subsequent days.

Within the above dose range, individual dosage should be calculated on a body-weight basis, and will depend upon the severity of symptoms and the causative agent. As a general guide, single doses should not exceed 3 mg/kg; however, in severe acute poisoning, single doses up to 5 mg/kg may be required initially.

Children: Dimercaprol Injection is well tolerated by children and dosage should be calculated on the basis of body-weight, using the same unit dose per kilogram of body-weight as for an adult under similar clinical circumstances.

Precautions: The use of Dimercaprol Injection does not eliminate the need for the general treatment of poisoning due to the particular heavy metal. Any abnormal reaction (e.g. pyrexia) occurring after the initial injection of dimercaprol should be assessed before continuing treatment.

Contra-indications, warnings, etc Dimercaprol Injection is contra-indicated in poisoning by iron and cadmium.

Dimercaprol Injection is contra-indicated in the presence of extensive hepatic insufficiency or damage.

Dimercaprol Injection should be used with caution in the hypertensive patient.

Side-effects are relatively frequent, but, at the therapeutic dosage usually employed, are seldom severe enough to warrant cessation of treatment and are almost invariably reversible. There is some evidence to indicate that 30–60 mg of ephedrine sulphate, by mouth, given half an hour before each injection of dimercaprol, will reduce these reactions. Also, a minimum interval of four hours between doses appears to reduce side-effects.

Dimercaprol Injection may cause the following side-effects particularly at the higher dosage levels:

Elevation of blood pressure accompanied by tachycardia; nausea and possibly vomiting; a burning sensation of the lips, mouth, throat and eyes; salivation and lachrymation; conjunctivitis; rhinorrhoea; muscle pain and spasm; abdominal pain; headache; tingling of the hands and other extremities; a feeling of constriction in the chest and throat; sweating of the forehead and hands.

Local pain may occur at the site of injection, and gluteal abscess has occasionally been encountered.

A side-effect apparently peculiar to children is a fever which develops after the second or third injection, and persists until treatment with dimercaprol is terminated.

Pharmaceutical precautions Dimercaprol Injection may become cloudy in cold weather; if this occurs, warm slightly before use.

Protect from light.

Legal category POM.

Package quantities 12 ampoules of 2 ml.

Further information Nil.

Product licence number 0014/5509.

FREAMINE® II

Presentation FreAmine II is a sterile, non-pyrogenic solution containing crystalline amino acids and electrolytes. Each 100 ml contains FreAmine II Amino Acid Mixture (Lysine Acetate and Cysteine Hydrochloride, H₂O added) 8.5 g, Phosphoric Acid NF 0.115 g, Sodium Bisulphite USP less than 0.10 g and Water for Injection USP to 100 ml.

The approximate concentration of amino acids in grams per 100 ml is:

Essential amino acids: L-Isoleucine 0.59, L-Leucine 0.77, L-Lysine Acetate 0.87 (free base 0.62), Methionine 0.45, L-Phenylalanine 0.48, L-Threonine 0.34, L-Tryptophan 0.13, L-Valine 0.56.

Non-essential amino acids: L-Alanine 0.60, L-Arginine 0.31, L-Histidine 0.24, L-Proline 0.95, L-Serine 0.50, Aminoacetic Acid (Glycine) 1.7, L-Cysteine Hydrochloride

ride H_2O less than 0.02, Alpha amino nitrogen greater than 80% of total nitrogen present.

The concentration of electrolytes in mmols per litre is: Sodium 10, Phosphate 10. The pH of the solution is approximately 6.6 and the calculated osmolarity is approximately 850 mOsm per litre.

A 500 ml unit of FreAmine II provides 39 g of protein equivalent and 6.25 g of sodium.

Uses FreAmine II provides, in concentrated form, a physiological ratio of biologically utilisable amino acids for protein synthesis. Given with concentrated sources of calories such as hypertonic dextrose or fat emulsions and with electrolytes, vitamins and minerals, it provides total parenteral nutrition. Administered peripherally, alone as an isotonic solution (2.8%) or with minimum caloric supplementation such as 5% dextrose, FreAmine I provides nutritional support and spares body protein.

Parenteral nutrition with FreAmine II is indicated when there is a requirement to prevent nitrogen loss or to treat negative nitrogen balance in patients where

- a) by the oral, gastrostomy or jejunostomy routes, the alimentary tract should not or cannot be used
- b) gastro-intestinal absorption of protein is impaired
- c) protein requirements are substantially increased, as with extensive burns.

Dosage and administration The total daily dose of FreAmine II will depend upon protein requirements and the response of the patient as determined by clinical judgement and laboratory data such as nitrogen balance and serum protein levels.

The recommended daily allowance of protein for healthy adults is approximately 0.9 g/kg of body weight and, for healthy, growing infants and children, 2.2 g/kg of body weight. However, it must be borne in mind that, in traumatised or under-nourished patients, the protein and caloric requirements may be substantially increased. In such cases, daily amino acid doses of approximately 0.0–1.5 g/kg of body weight for adults and 2–3 g/kg of body weight for children are generally adequate to satisfy protein needs and to promote positive nitrogen balance. Higher doses may be required in severely catabolic states but, particularly with infants, should be accompanied by frequent laboratory assessment. For protein sparing in the well-nourished patient who is not receiving significant additional calories, amino acid doses 1.0–1.7 g/kg/day will reduce nitrogen loss and spare body protein but, if rises in blood urea nitrogen exceed 20 mg% in 48 hours, the rate of administration should be reduced or infusion discontinued.

Central venous nutrition: For severely catabolic, depleted patients or those requiring long-term total parenteral nutrition, administration of FreAmine II with hypertonic dextrose solutions by central venous infusions should be considered.

Peripheral parenteral nutrition: For the moderately catabolic or depleted patient for whom the central venous route of administration is not indicated, FreAmine may be mixed with dextrose 5% solutions and infused by peripheral vein, supplemented, if necessary, by fat emulsion.

Protein sparing nutrition: In the well-nourished, mildly catabolic subject (such as the routine post-surgical patient requiring short-term parenteral nutrition only) protein sparing can be achieved by peripheral infusion of FreAmine II with or without dextrose.

Contra-indications, warnings, etc FreAmine II is contra-indicated in patients with renal failure, severe liver disease or hypersensitivity to amino acids.

Warnings: The administration of amino acids to a patient with hepatic insufficiency may result in a rise in blood ammonia; administration in the presence of impaired renal function may augment an increasing blood urea nitrogen and also presents the dangers associated with retention of electrolytes. The safety of the use of amino acid solutions in pregnant women has not been established.

Precautions: Frequent evaluation and laboratory determinations should be carried out during parenteral nutrition. Studies should include blood sugar, serum proteins, kidney and liver function tests, electrolytes, haemogram carbon dioxide content, serum osmolarities, blood cultures and blood ammonia levels. Should hyperammonaemia develop, administration of amino acids should be discontinued and the patient's clinical state re-evaluated. (This is particularly important in infants.) Care should be taken to avoid circulatory overload, particularly in patients with cardiac insufficiency. In myocardial infarction, amino acids should be given with dextrose.

Strongly hypertonic amino acid solutions and associated hypertonic dextrose solutions should be administered only by continuous infusion through a central venous catheter with the tip located in the vena cava.

Side-effects: Prolonged infusion of hypertonic solutions may cause phlebotrombosis extending from the site of infusion.

Pharmaceutical precautions Avoid freezing and excessive heat; store at temperatures between 2°C and 25°C. Protect from light. Do not use a solution unless clear and a vacuum is present.

Legal category POM.

Package quantities FreAmine II: 500 ml Intravenous Infusion Bottle.

FreAmine II Hyperalimentation Kit (50% Dextrose): Consisting of one 500 ml bottle of FreAmine II and one 1,000 ml bottle containing 500 ml of 50% Dextrose Injection with Transfer Set and Additive Cap.

Further information FreAmine II is a concentrated source of naturally occurring, biologically available amino acids for intravenous nutrition. When used as total parenteral nutrition in conjunction with adequate calories and other nutrients, FreAmine II is life-supporting – promoting anabolism and tissue synthesis, even over extended periods. No peptides or glutamic or aspartic acid, which can cause nausea and vomiting, are included in the formulation.

Product licence numbers

(50% Dextrose): 2737/0003

FreAmine II is McGaw product from The Boots Company Ltd, Nottingham.

FROBEN*

Presentation Light yellow, sugar-coated tablets containing either 50 mg or 100 mg of flurbiprofen. The

50 mg tablets are overprinted 'F50' in black; the 100 mg tablets are overprinted 'F100', also in black.

Uses Froben is a nonsteroidal anti-inflammatory agent which has significant anti-inflammatory, analgesic and antipyretic properties and is indicated in the treatment of rheumatoid disease, osteoarthritis, ankylosing spondylitis.

Dosage and administration The recommended daily dosage is 150–200 mg in three or four divided doses.

In patients with severe symptoms or disease of recent origin, or during acute exacerbations, the total daily dosage may be increased to 300 mg in divided doses.

Contra-indications, warnings, etc Froben should not be given to patients with peptic ulceration. Care should be taken when administering the drug to patients with asthma or who have experienced bronchospasm with other anti-inflammatory or analgesic agents. The safety of Froben during pregnancy or lactation has not been established. In animal experiments, no teratogenic effects were demonstrated but parturition was delayed and prolonged.

Side-effects: Dyspepsia, heartburn and headache are the commonest side-effects encountered. Occasional skin rashes have been reported.

Treatment of overdose: Gastric lavage and, if necessary, correction of serum electrolytes. There is no specific antidote to flurbiprofen.

Pharmaceutical precautions No special storage requirements are necessary.

Legal category POM.

Package quantities 50 mg Tablets: Packs of 100 and 500.

100 mg Tablets: Packs of 100.

Further information Froben is a potent non-steroidal anti-inflammatory agent which has significant anti-inflammatory, analgesic and antipyretic properties. It is a highly potent inhibitor of prostaglandin synthetase enzymes which are known to be associated with inflammation, pain and fever.

Studies in the treatment of rheumatoid disease, osteoarthritis and ankylosing spondylitis have indicated that Froben is as effective as the more potent of the established nonsteroidal anti-inflammatory agents and, in many patients, better tolerated. Long-term clinical studies have not revealed any evidence of significant effects upon the hepatic, renal or haemopoietic systems.

Because of the flexible dosage range, Froben is available as 50 mg tablets and 100 mg tablets, the higher strength preparation providing a convenient dose-form for those patients requiring 300 mg daily in divided doses.

Froben 50 mg Tablets 0014/0167

Froben 100 mg Tablets 0014/0168

FURAMIDE*

Presentation Furamide is presented as white, uncoated tablets, scored and embossed with the letters E.F. on one side. Each tablet contains Diloxanide Furoate BP 0.5 g.

Uses Furamide is used for the treatment of acute and chronic amoebic dysentery. It is rapidly effective in intestinal amoebiasis, but where there is liver involvement, specific treatment is recommended.

Dosage and administration *Adults:* 1 tablet 3 times daily for 10 days.

Children: Approx. 20 mg/kg body-weight (9 mg/lb) daily in divided doses for 10 days.

If required, a second course of treatment may be prescribed.

No special diets or enemas are required, and bed-rest is not necessary unless the clinical condition of the patient warrants it.

Contra-indications, warnings, etc There is no known contra-indication to the use of Furamide. The bacterial flora of the gut is not upset, and no serious side effects have been reported. Flatulence sometimes occurs but may usually be disregarded. More rarely, an urticaria rash may be seen.

Pharmaceutical precautions No special storage conditions are necessary.

Legal category POM.

Package quantities Packs of 15 and 250 tablets.

Further information Nil.

Product licence number 0014/5121.

FURAMIDE* COMPOUND

Presentation Furamide Compound is presented in tablets containing Furamide (Diloxanide Furoate BP 250 mg, Streptomycin Sulphate BP 150 mg and Chloroquine Phosphate BP 50 mg).

Uses Furamide Compound is indicated for the treatment of bacillary and amoebic dysentery.

It is intended for use in the treatment of diarrhoea when time or other circumstances does not allow for identification of the pathogen. The spectrum of streptomycin extends to all *Shigella* organisms, including *Shigella sonnei*, *flexneri* and *dysenteriae* (*shiga*), as well as to *Escherichia coli*. Furamide is specific against *Entamoeba histolytica*, and will destroy both vegetative and cyst forms of this parasite. Chloroquine phosphate is an acknowledged treatment for the hepatic complications of amoebic infection.

Dosage and administration *Adults:* 2 tablets 3 times daily for 5 days.

Children: 1 tablet 3 times daily for 5 days.

If considered necessary by the physician, treatment may be continued for a second 5 day period.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Furamide Compound. Side effects are uncommon. The Furamide component may cause flatulence in some patients but this may usually be disregarded. Headache, pruritus, blurring of vision and gastrointestinal disturbance may rarely be caused by chloroquine, but should disappear on withdrawal of the drug. As the streptomycin is not appreciably absorbed, toxic effects are unlikely and sensitivity reactions are rarely encountered.

Pharmaceutical precautions No special storage conditions are necessary.

Legal category POM.

Package quantities Pack of 15 tablets.

Further information Nil.

Product licence number 0014/5785.

HYDRENOX*

Presentation Hydrenox Tablets are Hydroflumethiazide Tablets BP each containing 50 mg of Hydroflumethiazide BP, oral diuretic of the thiazide group.

Uses Hydrenox is indicated in all cases where the reduction of fluid retention by diuresis is required, i.e. oedema of cardiac, renal or hepatic origin; premenstrual, iatrogenic and all other types of oedema. Hydrenox is also indicated in the treatment of hypertension, either used alone or in combination with a hypotensive agent.

Dosage and administration *Diuretic:* 50 to 200 mg daily, depending upon the severity of the oedema, as a single dose in the morning. The daily use should be given early enough to complete diuresis by bedtime. Doses of 25 to 50 mg on alternate days are usually adequate for maintenance therapy.

Hypotensive: 25 to 50 mg daily; when given as an adjunct to a specific hypotensive agent, the dose of the latter should be halved.

Dosage in children will be at the discretion of the physician; 1 mg per kg of body-weight daily has been suggested as suitable for most cases.

Contra-indications, warnings, etc

Electrolyte imbalance: All thiazide diuretics can produce a degree of electrolyte imbalance, especially in patients with renal or hepatic impairment or when dosage is high or prolonged. Serum electrolyte levels should be checked for abnormalities, particularly hypokalaemia which should be corrected by the addition of a potassium supplement to the regimen. Hydrenox does not contain a potassium supplement.

Digitalis intoxication: Sensitivity to digitalis may be increased by the kaliuretic effect of concurrent hydroflumethiazide. Patients should be observed for signs of digitalis intoxication and, if these appear, the dosage of digitalis reduced and a potassium supplement added to restore stability.

Jritic acid retention: Thiazide diuretics may raise serum uric acid levels with consequent exacerbation of gout in susceptible patients.

Diabetes: Thiazide diuretics sometimes lower carbohydrate tolerance and the insulin dosage of the diabetic patient may require adjustment.

Care is necessary when hydroflumethiazide is given to those with a known predisposition to diabetes.

Pregnancy: Thiazides cross the placental barrier; therefore it is reasonable to assume that side-effects occurring in the adult may also appear in the neonate.

Treatment of overdosage: Monitor blood pressure and renal electrolytes. Treatment is symptomatic.

Pharmaceutical precautions Recommended storage conditions, 5° to 20°C.

Legal category POM.

Package quantities Bottle of 100, bottle of 500.

Further information Nil.

Product licence number 0014/5119.

HYDROCORTISTAB* INJECTION

Presentation Hydrocortistab Injection is Hydrocortisone Acetate Injection BP, containing 25 mg of Hydrocortisone Acetate BP per ml.

Uses Hydrocortistab Injection is indicated for the local treatment, by intra-articular or peri-articular injection of arthritic conditions such as rheumatoid arthritis and osteoarthritis when few joints are involved and in traumatic arthritis, except when associated with fractures into the joint. It is also suitable for the symptomatic treatment, by the local injection, of certain non-articular inflammatory conditions such as inflamed tendon-sheaths and bursae.

Hydrocortistab Injection is not suitable for the production of systemic effects.

Dosage and administration By intra-articular or peri-articular injection, 5 mg to 50 mg depending upon the size of the joint. Not more than three joints should be treated in one day.

Contra-indications, warnings, etc As with all corticosteroids, the administration of Hydrocortistab Injection is contra-indicated when the affected site is infected. It should not be injected directly into tendons, nor should it be injected into spinal or any other than true diarthrodial joints.

Caution: Since joints and tissues injected with corticosteroids have an increased susceptibility to infection, local injections of Hydrocortistab should be carried out with full aseptic precautions.

Side-effects: The principal side-effect encountered with local injections of corticosteroids is a temporary local exacerbation, with increased pain and swelling. This usually subsides after a few hours. In certain circumstances, particularly after high or prolonged local dosage, corticosteroids can be absorbed in amounts sufficient to produce systemic effects.

Treatment of overdosage: Treatment is symptomatic but is unlikely to be required.

Pharmaceutical precautions Store between 15°C to 20°C; protect from light.

Legal category POM.

Package quantities Vial of 5 ml.

Further information Nil.

Product licence number 0014/5510.

LIGNOSTAB*

Presentation Lignostab is injection of lignocaine hydrochloride 2%. It is supplied in glass cartridges designed for use with dental-type cartridge syringes. Each cartridge contains 2.0 ml of solution.

Uses Lignostab is a local anaesthetic. It is mainly for use in dental procedures where the addition of a vasoconstrictor is either contra-indicated or not required. Since Lignostab contains no vasoconstrictor, the local anaesthetic effect is of relatively short duration.

Dosage and administration Lignostab is given by

injection, in dental procedures, into the gum. The amount of Lignostab required to produce adequate anaesthesia must be determined on an individual basis, bearing in mind that it is desirable to use the minimal effective dose.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to lignocaine. Injection into inflamed or infected areas is to be avoided.

Caution: Care should be taken to avoid the accidental intravenous injection of Lignostab.

Side-effects: Provided the correct injection technique is used and the lowest effective dose employed, side-effects with Lignostab are extremely rare. However, idiosyncratic reactions to local anaesthetics have been reported in some patients.

Toxic effects: Transient drowsiness and amnesia proceeding to severe central nervous system depression may sometimes occur, but excitation of the central nervous system is uncommon.

Pharmaceutical precautions *Recommended storage conditions:* 2–25°C; protect from light.

Legal category POM.

Package quantities Jars of 50 cartridges.

Further information Shelf-life of at least two years.

Product licence number 0014/5368.

LIGNOSTAB*-A LIGNOSTAB*-A100

Presentation Lignostab-A is injection of lignocaine hydrochloride 2% with adrenaline 1: 80,000. Lignostab-A100 is injection of lignocaine hydrochloride 2% with adrenaline 1: 100,000. Both are supplied in glass cartridges designed for use with dental-type syringes. Each cartridge contains 2.0 ml of solution.

Uses Lignostab-A and Lignostab-A100 are local anaesthetics, mainly for use in dental procedures.

Both these preparations include a vasoconstrictor (adrenaline), the effect of which is to prolong the local anaesthesia by delaying the diffusion of the anaesthetic into the surrounding tissues.

Dosage and administration Lignostab-A and Lignostab-A100, in dental procedures, are injected into the gum. The amount of either preparation needed to provide adequate anaesthesia must be determined on an individual basis, bearing in mind that it is desirable to use the minimal effective dose.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to lignocaine. Lignostab-A and -A100 should not be injected into inflamed or infected areas. Because of their adrenaline content, these preparations should be used with caution in patients with hypertension. Lignostab-A and -A100 are contra-indicated in patients taking antidepressants of the tricyclic group.

Caution: Care should be taken to avoid the accidental intravenous injection of Lignostab-A or -A100. Lignostab-A and -A100 should not be injected into extremities.

Side-effects: Provided the correct injection technique is used and the lowest effective dose employed, side-effects with Lignostab-A and -A100 are extremely rare. However, idiosyncratic reactions to local anaesthetics have been reported in some patients. The injection of

excessive amounts of Lignostab-A or -A100 may, due to the adrenaline content, cause ischaemia. This can be followed by a reactive hyperaemia resulting in post-extraction bleeding.

Toxic effects: Transient drowsiness and amnesia proceeding to severe central nervous system depression may occur, but excitation of the central nervous system is uncommon.

Treatment of overdosage: Respiratory failure may need assisted respiration. The circulation can be controlled with electrolyte or plasma infusions. If convulsions develop, these can be controlled by a short-acting barbiturate.

Pharmaceutical precautions *Recommended storage conditions:* 2–25°C. Protect from light.

Legal category POM.

Package quantities Jars of 50 Boxes of 500.

Further information Shelf-life of at least two years.

Lignostab-A 0014/5384

Lignostab-A100 0014/5385

LIGNOSTAB*-N

Presentation Lignostab-N is injection of lignocaine hydrochloride 2% with noradrenaline 1:80,000. It is supplied in glass cartridges designed for use with dental-type cartridge syringes. Each cartridge contains 2.0 ml of solution.

Uses Lignostab-N is a local anaesthetic, mainly for use in dental procedures. Lignostab-N includes the vasoconstrictor noradrenaline, the effect of which is to prolong the local anaesthesia by delaying the diffusion of the anaesthetic into the surrounding tissues.

Lignostab-N provides an alternative to local anaesthetics which contain adrenaline as a vasoconstrictor.

Dosage and administration Lignostab-N is given by injection, in dental procedures, into the gum. The amount required to provide adequate anaesthesia must be determined on an individual basis, bearing in mind that it is desirable to use the minimal effective dose.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to lignocaine. Injection into inflamed or infected areas is to be avoided. Because of the noradrenaline content, Lignostab-N should be used with caution in patients with hypertension. Lignostab-N is contra-indicated in patients taking antidepressants of the tricyclic group.

Caution: Care should be taken to avoid the accidental intravenous injection of Lignostab-N.

Side-effects: Provided the correct injection technique is used and the lowest effective dose employed, side-effects are extremely rare with Lignostab-N.

However, idiosyncratic reactions to local anaesthetics have been reported in some patients. The injection of excessive amounts of Lignostab-N may, due to the vasoconstrictor, cause ischaemia. This can be followed by a reactive hyperaemia and result in post-extraction bleeding.

Toxic effects: Transient drowsiness and amnesia proceeding to severe central nervous system depression may sometimes occur, but excitation of the central nervous system is uncommon.

Treatment of overdosage: Respiratory failure may need assisted respiration. The circulation can be maintained with electrolyte or plasma infusions. Should convulsions develop, these can be controlled with a short-acting barbiturate.

Pharmaceutical precautions *Recommended storage conditions:* 2–25°C. Protect from light.

Legal category POM.

Package quantities Jars of 50 and boxes of 500.

Further information Shelf-life of at least two years.

Product licence number 0014/5386.

MUSTINE HYDROCHLORIDE FOR INJECTION BP

Synonyms: Nitrogen Mustard. Mechlorethamine Hydrochloride USP, Mustargen Hydrochloride, Chlorethazine Hydrochloride, Chloromethine Hydrochloride INN, 'HN₂'.

Presentation Mustine hydrochloride is supplied in sterile vials each containing 10 mg of the powder. The injection is prepared by dissolving this in Sodium Chloride Injection BP 0.9% w/v or Water for Injections BP.

Mustine hydrochloride is di (2-chloroethyl) methylamine hydrochloride. It is a white or almost white hygroscopic, vesicant, crystalline powder or mass and is very soluble in water. A 0.2% solution in water has a pH of 3 to 5.

Uses The principal use of mustine hydrochloride is as part of combination treatment for Hodgkin's disease. It is also sometimes used in non-Hodgkin's lymphomas and carcinoma of bronchus, ovary and breast. It may be injected into pleural or peritoneal cavities for the treatment of malignant effusions. It may be applied locally for the treatment of mycosis fungoides.

Dosage and administration *Malignancy:* The normal intravenous dose of mustine hydrochloride is 0.1 mg per kg body-weight daily for three or four days. In selected cases, larger doses of 0.2 to 0.3 mg per kg body-weight daily may be given, but the course should then be limited to two injections. Alternatively, a single treatment using 3.4 mg per kg body-weight (15 mg per square metre body surface area) can be administered. The term 'body-weight' is defined, in this case, as the actual body-weight at the time of treatment except in cases where the weight has been artificially increased by oedema, ascites, or other fluid collections. The weight of the body before the increase is used in such cases.

UNDER NO CIRCUMSTANCES SHOULD MUSTINE BE GIVEN INTRAMUSCULARLY.

A repeat course of mustine therapy should not be undertaken for at least 6 weeks or until the bone-marrow has recovered its haemopoietic activity.

Preparation of intravenous injection: A fresh solution is prepared by dissolving 10 mg of mustine hydrochloride in 10 ml of Sodium Chloride Injection BP 0.9% w/v, or Water for Injections BP. The best method of administration is to set up an intravenous drip of Sodium Chloride Injection BP 0.9% w/v or Dextrose Injection BP 5% w/v; the required dose of mustine prepared as above, is then injected into the tubing. This avoids the hazard of extravasation during injection. The drip rate should be 10 drops per minute and the injection of mustine should

be carried out over 2 minutes. The drip should then be reduced to 20 drops per minute.

Alternatively the concentrated solution of mustine hydrochloride is freshly prepared as above and transferred aseptically to 500 ml of Sodium Chloride Injection BP 0.9% w/v.

Pleural effusions: Mustine is sometimes injected into the peritoneal or pleural cavities. There are minor variations in the techniques. Half an hour before the injection a short acting barbiturate such as oral quinalbarbitone 0.2 g, and chlorpromazine 25 mg should be given to reduce the nausea. Most articles advise the use of paracentesis to remove as much fluid as possible. Mustine hydrochloride may be injected into the cavity in a simple dose up to 0.4 mg/kg body-weight (15 to 30 mg of mustine in about 100 to 200 ml of normal saline).

The quinalbarbitone and chlorpromazine may be repeated if there is further nausea.

Mycosis fungoides: Mycosis fungoides may be treated by topical application of a dilute solution of mustine hydrochloride. Various strengths of mustine hydrochloride have been used but 20 mg in 100 ml of 0.9% w/v sodium chloride solution or water is frequently recommended. The solution is applied to the affected cutaneous areas using a gauze pad. The person applying the solution should wear polyvinylchloride gloves to give protection. Some patients develop an allergic contact dermatitis after topical application of mustine hydrochloride.

Contra-indications, warnings, etc

Warning: To prevent blistering, gloves should be worn when handling mustine hydrochloride, and because of its irritating powers the drug should be kept well away from the nose and eyes. Polyvinylchloride gloves give adequate protection but rubber and polyethylene gloves have been shown to be ineffective. Mustine hydrochloride accidentally spilled on the skin should be washed away immediately with large amounts of water or, if at hand, sodium carbonate solution or an isotonic solution of sodium thiosulphate. If mustine is accidentally splashed into the eye it should be immediately washed out for a long period of time with large amounts of water and, if available, irrigated with isotonic solution of sodium thiosulphate. The person concerned then should be seen by an ophthalmologist.

After treatment with mustine all apparatus, including PVC gloves, should be washed thoroughly. A 2.5% solution of sodium carbonate is particularly suitable for the lavage.

Adverse reactions and precautions: Nausea and vomiting often occur during the eight hours following injection. The administration of chlorpromazine, either alone or with a suitable barbiturate such as quinalbarbitone, often helps to control this and should be given thirty to sixty minutes before injection, repeated if necessary.

Transient anorexia, occasional diarrhoea and fever may occur. Peptic ulcers have been reported.

Severe haemopoietic depression may follow mustine therapy, with lymphocytopenia, granulocytopenia and occasionally agranulocytosis. It may lead to severe anaemia and thrombocytopenia. Leucocytes and platelet counts in peripheral blood start to fall about one week after treatment with a nadir between 14 and 18 days. During the same period there is a fall in haemoglobin level. Both leucocyte and platelet counts return to normal before the end of the fourth week. Mustine should not be used in patients with severe leucopenia, thrombocy-

topenia or anaemia and in coexistent or suspected granuloma. Extravasation during injection should be avoided as this may cause severe local reactions and even local tissue necrosis. If extravasation does occur during injection the involved area should be infiltrated with isotonic sodium thiosulphate solution followed by the application of an ice compress intermittently for six to twelve hours.

This product should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

If considered for use in pregnancy the risk to the foetus should be weighed against the potential benefits to the patient. The drug possesses foetotoxic and teratogenic potential.

Thrombophlebitis and venous thrombosis are potential complications to mustine therapy.

In non-pregnant women delayed menstruation or temporary amenorrhoea may follow the treatment. In males a reduction of active spermatogenesis has been reported. Hyperuricaemia may develop in patients with large tumour masses.

Treatment of overdose: Sodium thiosulphate will neutralise an injection of mustine hydrochloride BUT ONLY IF GIVEN IMMEDIATELY AFTERWARDS. Each 10 mg mustine requires 640 mg sodium thiosulphate given as an isotonic solution. This is equivalent to approximately 1.5 ml of a 50% solution of sodium thiosulphate diluted with 20 ml 0.9% sodium chloride solution or approximately 21 ml of 3% sodium thiosulphate solution.

Stability: An early study of the stability of mustine hydrochloride in saline solution at room temperature, using a colorimetric assay method, showed that the solution lost 7% of alkylating potential per hour. A later study indicated that solutions of mustine hydrochloride stored at room temperature lost approximately 50% of activity in one to two months.

Studies in Boots' laboratories storing 10 mg mustine hydrochloride in 20 ml Water for Injections showed no significant loss of activity over the first 10 days. Thereafter a slow but steady loss of activity occurred until the 40th day resulting in an overall loss of 20%.

Pharmaceutical precautions Store at 2° to 15°C.

Legal category POM.

Package quantities Pack of 10 vials.

Further information Nil.

Product licence number 0014/5512.

NEULENTE®

Presentation Neulente insulin injection is Insulin Zinc Suspension Injection BP (Purified), a cloudy neutral suspension of purified insulin consisting of 3 parts of insulin zinc suspension (amorphous) and 7 parts of insulin zinc suspension (crystalline). pH 7.2 ± 0.3

It is available in strengths of 40 and 80 units per ml.

This insulin is prepared from ox pancreas.

Uses For the management of diabetes mellitus.

Dosage and administration

Adults and children: The daily unit dosage of insulin is determined by the physician in accordance with the patient's requirements.

The site of each injection should be changed according to a suitable routine.

Insulin Zinc suspension should be well mixed by inverting the vial several times before use. It is administered by subcutaneous or intramuscular injection.

Subcutaneous: Onset of action occurs within 2 hours, with an overall duration of action which may extend to 28–30 hours.

Intramuscular: Onset of action is more rapid and overall duration of action shorter than with the subcutaneous route, assuming adequate vascular perfusion.

Insulin zinc suspension should not be given intravenously.

Contra-indications, warnings, etc Hypoglycaemia is an absolute contra-indication.

Insulin dosage requirement may change if the species of origin, type, or purity of insulin is changed.

Interactions: Insulin requirements may be affected by changes in life-style, pregnancy, infections, other medical conditions or certain drug therapies.

Insulin requirements may be increased by the concomitant use of corticosteroids, oral contraceptives, thyroid hormones, thiazide diuretics and may be decreased by beta-adrenergic blocking agents and monoamine oxidase inhibitors. Since the clinical effect is variable, diabetic patients should be carefully observed initially when any drug therapy is required.

Side-effects: The most important side-effect is hypoglycaemia. Reduction of hyperglycaemia in newly diagnosed diabetics may alter visual refraction.

Bovine insulin, like any other foreign protein, is potentially immunogenic.

Local reactions at the injection site may include transient erythema, induration, urticaria and oedema. These usually resolve with continuing usage of insulin.

True generalised hypersensitivity reactions approaching anaphylaxis are very rare.

Clinical evidence suggests that purified insulins are unlikely to cause localised lipodystrophies. However, at present, this possibility cannot be totally excluded.

Treatment of Overdosage: The symptoms and signs of hypoglycaemia depend on the patient's clinical state and on the rate and extent of the fall in blood glucose. If possible, dextrose, sucrose or rapidly available carbohydrate should be taken by mouth. Failing this, hypoglycaemia, should be reversed as rapidly as possible by intravenous injection of 50% Dextrose injection. Alternative emergency treatments include the subcutaneous injection of up to 1 ml of adrenaline injection 1: 1000, or the subcutaneous, intramuscular or intravenous injection of lyophilised glucagon 0.5–1.0 mg (1 unit = 1.0 mg). Both adrenaline and glucagon injections mobilise hepatic glycogen, but the effect is short-lived and must be supplemented by freely available carbohydrate as soon as possible.

Pharmaceutical precautions Store at 2°–10°C. Do not freeze. Avoid direct sunlight.

Legal category P.

Package quantities

40 units per ml: 10 ml vial.

80 units per ml: 10 ml vial.

Further information *Mixing in the Syringe:* Insulin zinc suspension (purified) should not be mixed with other insulins.

Neulente 80 units per ml: 0014/0225

NEUPHANE®

Presentation Neuphane insulin injection is Isophane Insulin Injection BP (Purified), a cloudy neutral suspension of an insulin (purified)/protamine complex. pH 7.2 ± 0.3

It is available in strengths of 40 and 80 units per ml.
This insulin is prepared from ox pancreas.

Uses For the management of diabetes mellitus.

Dosage and administration

Adults and children: The daily unit dosage of insulin is determined by the physician in accordance with the patient's requirements.

The site of each injection should be changed according to a suitable routine.

Isophane insulin injection should be well mixed by inverting the vial several times before use. It is administered by subcutaneous or intramuscular injection.

Subcutaneous: Onset of action occurs within 2 hours, with an overall duration of action which may extend to 18–28 hours.

Intramuscular: Onset of action is more rapid and overall duration of action shorter than with the subcutaneous route, assuming adequate vascular perfusion.

Isophane insulin injection should not be given intravenously.

Contra-indications, warnings, etc Hypoglycaemia is an absolute contra-indication.

Insulin dosage requirements may change if the species of origin, type, or purity of insulin is changed.

Interactions: Insulin requirements may be affected by changes in life-style, pregnancy, infections, other medical conditions or certain drug therapies.

Insulin requirements may be increased by the concomitant use of corticosteroids, oral contraceptives, thyroid hormones, thiazide diuretics and may be decreased by beta-adrenergic blocking agents and monoamine oxidase inhibitors. Since the clinical effect is variable, diabetic patients should be carefully observed initially when any drug therapy is required.

Side-effects: The most important side-effect is hypoglycaemia. Reduction of hyperglycaemia in newly diagnosed diabetics may alter visual refraction.

Bovine insulin and protamine, like any other foreign proteins, are potentially immunogenic.

Localised reactions at the injection site may include transient erythema, induration, urticaria and oedema. These usually resolve with continuing usage of insulin.

True generalised hypersensitivity reactions approaching anaphylaxis are very rare.

Clinical evidence suggests that purified insulins are unlikely to cause localised lipodystrophies. However, at present, this possibility cannot be totally excluded.

Treatment of Overdosage: The symptoms and signs of hypoglycaemia depend on the patient's clinical state and on the rate and extent of the fall in blood glucose.

If possible, dextrose, sucrose or rapidly available carbohydrate should be taken by mouth. Failing this, hypoglycaemia should be reversed as rapidly as possible by intravenous injection of 50% Dextrose injection. Alternative emergency treatments include the subcutaneous injection of up to 1 ml of adrenaline injection 1:1000, or the subcutaneous, intramuscular or intravenous injection of lypophilised glucagon 0.5–1.0 mg (1 unit = 1.0 mg). Both adrenaline and glucagon injections mobilise hepatic glycogen, but the effect is short-

lived and must be supplemented by freely available carbohydrate as soon as possible.

Pharmaceutical precautions Store at 2°–10°C. Do not freeze. Avoid direct sunlight.

Legal category P.

Package quantities

40 units per ml: 10 ml vial.

80 units per ml: 10 ml vial.

Further information *Mixing in the Syringe:* Isophane insulin injection (purified) can be mixed with neutral insulin injection (purified).

If, on medical advice isophane insulin injection (purified) is to be mixed in the syringe with neutral insulin injection (purified), the following procedure should be adopted:—

1. Inject a volume of air equivalent to the dose of isophane insulin injection into the bottle of isophane insulin injection without inverting the bottle or withdrawing the dose.

2. Inject a volume of air equivalent to the dose of neutral insulin injection into the bottle of neutral insulin injection and withdraw the dose in the usual way.

3. Re-insert the needle into the isophane insulin injection and withdraw the appropriate dose.

Neuphane 80 units per ml 0014/0227

NEUSULIN®

Presentation Neusulin insulin injection is Neutral Insulin Injection BP (Purified), a clear neutral solution of purified crystalline insulin. pH 7.15 ± 0.55.

It is available in strengths of 40 and 80 units per ml.

This insulin is prepared from ox pancreas.

Uses For the management of diabetes mellitus.

Dosage and administration

Adults and children: The daily unit dosage of insulin is determined by the physician in accordance with the patient's requirements.

The site of each injection should be changed according to a suitable routine. Neutral insulin injection is administered by subcutaneous, intramuscular or intravenous injection. Accidental intravascular injection should be avoided.

Subcutaneous: Onset of action occurs within 30–60 minutes, with an overall duration of action of approximately 6–8 hours. Consequently, 2 or 3 injections daily before meals may be appropriate if not used in combination with other insulins.

Intramuscular: Onset of action is more rapid and overall duration of action shorter than with the subcutaneous route, assuming adequate vascular perfusion.

Intravenous: Onset of action is most rapid and duration of action shortest with this route. It is usually reserved either for investigational purposes, or for the treatment of diabetic ketoacidosis.

Contra-indications, warnings, etc Hypoglycaemia is an absolute contra-indication.

Insulin dosage requirement may change if the species of origin, type or purity of insulin is changed.

Interactions: Insulin requirements may be affected by

changes in life-style, pregnancy, infections, other medical conditions or certain drug therapies.

Insulin requirements may be increased by the concomitant use of corticosteroids, oral contraceptives, thyroid hormones, thiazide diuretics and may be decreased by beta-adrenergic blocking agents and monoamine oxidase inhibitors. Since the clinical effect is variable, diabetic patients should be carefully observed initially when any drug therapy is required.

Side-effects: The most important side-effect is hypoglycaemia. Reduction of hyperglycaemia in newly diagnosed diabetics may alter visual refraction.

Bovine insulin, like any other foreign protein, is potentially immunogenic.

Local reactions at the injection site may include transient erythema, induration, urticaria and oedema. These usually resolve with continuing usage of insulin.

True generalised hypersensitivity reactions approaching anaphylaxis are very rare.

Clinical evidence suggests that purified insulins are unlikely to cause localised lipodystrophies. However, at present, this possibility cannot be totally excluded.

OCUSOL* EYE DROPS

Presentation Ocusol Eye drops are a sterile preparation of Sulphacetamide Sodium BP 5% w/v, Zinc

Sulphate BP 0.1% w/v and Cetrimide BP 0.01% w/v in an aqueous base of adjusted tonicity, viscosity and pH.

Uses Ocusol Eye drops are indicated in the treatment of superficial eye infections such as blepharitis, conjunctivitis and infections of the cornea. They may also be used as a prophylactic measure against infection following eye injury or the removal of foreign bodies from the eye.

Dosage and administration One drop to be instilled into the affected eye three or four times daily.

Contra-indications, warnings, etc There are no known contra-indications to the use of Ocusol; no side-effects associated specifically with Ocusol have been reported.

Warning: Ocusol should not be used later than four weeks after the bottle has been opened.

Treatment of overdosage: There is no toxicological hazard even if the whole bottle is swallowed.

Pharmaceutical precautions None.

Legal category POM.

Package quantities 10 ml dropper-bottle.

Further information The formulation of Ocusol has an antibacterial activity equivalent approximately to that of a 30% solution of sulphacetamide sodium but is much less likely to cause local irritation than the latter more concentrated solution.

Product licence number 0014/5164.

POLYFUSOR* DEXTROSE INJECTIONS

Presentation Polyfusor Dextrose Injections are sterile, pyrogen-free solutions of Anhydrous Dextrose in Water for Injections prepared to British Pharmacopoeial standards. The solutions are enclosed in disposable, semi-rigid containers of pure polyethylene and are available in the following strengths:

Concentration of dextrose w/v (%)	Energy value in calories per litre	Concentration of anhydrous dextrose in grams per litre
2.5	94	25
5.0	188	50
10.0	375	100
20.0	750	200
40.0	1,500	400
50.0	1,875	500

Uses Polyfusor Dextrose Injections are given by intravenous infusion and are indicated in simple dehydration, carbohydrate depletion, hypoglycaemic coma. They can also be used to provide a temporary increase in blood volume in haemorrhage and shock.

Dosage and administration The volume, strength and rate of infusion of dextrose solutions given intravenously will depend upon the requirements of the patient and the judgement of the physician.

Contra-indications, warnings, etc

Contra-indications: Diabetes, except as a treatment for hypoglycaemia. The intravenous infusion of dextros:

solutions may be hazardous in patients with impaired hepatic or renal function.

Precautions: The intravenous infusion of dextrose solutions should not be too rapid or very prolonged. The rapid administration of large volumes of these solutions can cause water intoxication; conversely, infusion over a long period can cause dehydration.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdosage: Introduce measures to correct water intoxication or dehydration as appropriate (see 'Precautions').

Pharmaceutical precautions Recommended storage conditions: 2–25°C. The shelf-life of Polyfusor Dextrose Injections is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml. Carton of 10 × 1,000 ml.

Further information Polyfusor Dextrose Injections provide a range of dextrose solutions designed to meet the many and varied requirements of intravenous carbohydrate therapy. Prepared to an exceptionally high standard, the solutions are supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, anti-oxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see 'Shelf-life'). Polyfusor Dextrose Injections are part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

POLYFUSOR* FRUCTOSE SOLUTIONS

Representation Polyfusor Fructose Solutions are sterile, hydrogen-free solutions of Laevulose in Water for Injections prepared to British Pharmacopoeial standards. The solutions are enclosed in disposable, semi-rigid containers of pure polyethylene and are available in the following strengths. (See table in next column.)

Uses Polyfusor Fructose Solutions are given by intravenous infusion and are indicated for conditions associated with carbohydrate deficiency. Fructose accelerates

Concentrations of laevulose w/v (%)	Energy value in calories per litre	Concentration of laevulose in grams per litre
10	375	100
20	750	200

ates the metabolism of ethyl alcohol and may be given in the treatment of acute ethanol poisoning. Fructose is a suitable source of calories in patients with renal failure unable to tolerate oral feeding. Neonatal hypoglycaemia occurring in newborn infants of diabetic mothers can be prevented by injection of fructose into the umbilical vein.

Dosage and administration The volume, strength and rate of infusion of fructose solutions given intravenously will depend upon the requirements of the patients and the judgement of the physician. Administration should be slow.

Contra-indications, warnings, etc

Contra-indications: Fructose should not be given to patients with fructose intolerance, or to patients with methyl alcohol poisoning as it enhances the oxidation of methyl alcohol to formaldehyde. Fructose should not be administered to patients in shock, with severe hepatic disease or uncontrolled diabetes mellitus.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. Reported side-effects of large doses include facial flushing epigastric pain and sweating.

Treatment of overdosage: Treatment consists of withdrawal of the infusion.

Pharmaceutical precautions Recommended storage conditions: 2–25°C. The shelf-life of Polyfusor Fructose Solutions is one year. To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use also must be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Prepared to an exceptionally high standard, Polyfusor Fructose Solutions are supplied in disposable, semi-rigid containers made from a specially developed neutral plastic, free from plasticisers, anti-oxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for long periods under normal storage conditions (see 'Shelf-life'). Polyfusor Fructose Solutions are part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality, and extent, can meet the general and specific requirements of modern intravenous therapy.

POLYFUSOR* GLYCEROL AND SALINE INJECTION

Presentation Polyfusor Glycerol Solution is a sterile pyrogen-free solution of Glycerol and Sodium Chloride in Water for Injections prepared to British Pharmacopoeial standards. The solution contains Glycerol 10 parts (by weight) and Sodium Chloride 0.9% 100 parts (by volume). Approximate ion concentration in millimoles per litre: Sodium 143, Chloride 143.

Uses Polyfusor Glycerol Solution is used in the treatment of acute cerebral oedema.

Dosage and administration The volume and rate of infusion of Glycerol and Saline given intravenously will depend upon the requirements of the patient and the judgement of the physician. Glycerol has been given intravenously as a 10% solution in 0.9% Sodium chloride Solution in a dosage of 1.2 g per kg body weight and every 24 hours for up to six days.

Contra-indications, warnings, etc

Contra-indications: Cardiac or renal failure.

Precautions: The infusion must be given slowly.

Side-effects: Haemolysis, haemoglobinuria, and renal failure. Local phlebitis may occur.

Treatment of overdosage: Discontinue infusion.

Pharmaceutical precautions *Recommended storage conditions:* 2°C–25°C. The shelf-life of Polyfusor Glycerol and Saline Injection is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Glycerol and Saline Injections is designed to meet the requirements of intravenous therapy. Prepared to an exceptionally high standard, the solution is supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, antioxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see Shelf-life). Polyfusor Glycerol and Saline Injection is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number 0014/5853.

POLYFUSOR* HARTMANN'S SOLUTION

Presentation Polyfusor Hartmann's Solution is a sterile pyrogen-free preparation of Compound Sodium Lactate Injection prepared to British Pharmacopoeial

standards. The solution is enclosed in disposable semi-rigid containers of pure polyethylene.

Approximate ion concentration in millimoles per litre Sodium, 131; Chloride, 111; Calcium, 2; Potassium, 5 Bicarbonate (as Lactate) 29.

Uses Polyfusor Hartmann's Solution is administered by intravenous infusion and is used for the treatment of dehydration with acidosis. It may also be used to expand extracellular fluids or restore extracellular electrolyte Hartmann's Solution may also be used in the treatment of diabetic coma and the fluid and electrolyte losses associated with infantile diarrhoea.

Dosage and administration The volume, strength and rate of infusion of compound sodium lactate solution given by intravenous infusion will depend upon the requirements of the patient and the judgement of the physician. A dosage of 300 ml per hour should not be exceeded.

Contra-indications, warnings, etc

Contra-indications: Hartmann's Solution should not be administered to patients with severe liver damage who would be unable to convert lactate to bicarbonate.

Precautions: Hartmann's Solution should be used with caution in patients with cardiac failure, hypertension impaired renal function, peripheral and pulmonary oedema, and in toxæmia of pregnancy.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdosage: Administer a suitable diuretic

Pharmaceutical precautions *Recommended storage conditions:* 2–25°C. The shelf-life of Polyfusor Hartmann's Solution is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml. Carton of 10 × 1,000 ml.

Further information Polyfusor Hartmann's Solution is designed to meet the varied requirements of fluid therapy. Prepared to an exceptionally high standard, the solutions are supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, anti-oxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see 'Shelf life'). Polyfusor Hartmann's Solution is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number

Hartmann's Solution 0014/5410.

***OLYFUSOR* MANNITOL INJECTIONS**

Presentation Polyfusor Mannitol Injections are sterile, pyrogen-free solutions of Mannitol in Water for Injections prepared to British Pharmacopoeial standards. The solutions are enclosed in containers of pure polyethylene. Polyfusor Mannitol Injections are available as solutions of 10% and 20% w/v.

Uses Polyfusor Mannitol Injections are administered by intravenous infusion and are used as an osmotic diuretic alone or to supplement the action of other diuretics in order to promote renal function. Other uses include the treatment of oliguria and to assist the elimination of drugs such as aspirin and barbiturates which are excreted by the kidneys.

Dosage and administration The volume, strength and rate of infusion of mannitol solutions given in intravenous infusion will depend upon the requirements of the patient and the judgement of the physician. A dose of 200 g daily by intravenous infusion should not be exceeded.

Contra-indications, warnings, etc Mannitol is contra-indicated in cases of metabolic oedema associated with abnormal capillary fragility. If renal flow is inadequate, water intoxication is likely in patients receiving intravenous mannitol; therefore, its use in oedematous conditions associated with diminished cardiac reserve should only be considered if the advantages outweigh the risks. Patients with impaired renal function should be given a test dose of 200 mg/kg body weight administered over five minutes and, if 40 ml or more of urine is produced in an hour, mannitol may be given in therapeutic doses.

Solutions of mannitol given in intravenous infusion should be administered slowly and should not be mixed with blood in transfusion apparatus.

Side-effects: Rapid intravenous infusion of mannitol may produce headache, chills or chest pain. It may also depress respiration by altering the acid-base and electrolyte balance of the body fluids. Convulsions have been noted in patients administered excessive doses of mannitol solution.

Treatment of overdosage: Introduce measures to correct water and electrolyte imbalance.

Pharmaceutical precautions Recommended storage conditions: 20–30°C. Exposure to lower temperatures may cause deposition of crystals. Carefully examine the solution for crystals immediately before use. If necessary redissolve by raising the temperature to 60°C. Cool to blood heat before use. The shelf-life of Polyfusor Mannitol Injection is three years. To prevent gross contamination of the outside surface of the Polyfusor,

the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Mannitol Injections are designed to meet the many requirements of intravenous diuretic therapy. Prepared to an exceptionally high standard, the solution is supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, antioxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of Polyfusor is impervious to micro-organisms and virtually impermeable to water-vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see 'Shelf-life'). Polyfusor Mannitol Injections are part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

***POLYFUSOR* PAEDIATRIC ELECTROLYTE**

Presentation Polyfusor Paediatric Electrolyte Solution is a sterile pyrogen-free solution prepared to British Pharmacopoeial standards. The solution is enclosed in disposable, semi-rigid containers of pure polyethylene.

Uses Polyfusor Paediatric Electrolyte Solution is given by intravenous infusion and is an electrolyte replacement solution for use in the treatment of infants, particularly where there is Potassium loss.

Dosage and administration The volume and rate of infusion of Polyfusor Paediatric Electrolyte Solution given intravenously will depend upon the requirements of the infant and the judgement of the physician.

Contra-indications, warnings, etc

Contra-indications: Severe liver damage, since such patients would be unable to convert lactate to bicarbonate; impaired renal or cardiac function.

Polyfusor Paediatric Electrolyte

Anhydrous Dextrose

Sodium 38
Potassium 35
Chloride 45
Phosphate 7.5
Bicarbonate (as lactate) 18

Water for Injections BP to 100

Precautions: Because of the high potassium level, this infusion must be given slowly.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdose: Discontinue infusion and treat symptomatically.

Pharmaceutical precautions *Recommended storage conditions:* 2°C–25°C. The shelf-life of Polyfusor Paediatric Electrolyte Solution is one-and-a-half years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Paediatric Electrolyte Solution is designed to meet the requirements of intravenous electrolyte replacement therapy. Prepared to an exceptionally high standard, the solution is supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, antioxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see Shelf-life). Polyfusor Paediatric Electrolyte Solution is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number 0014/5799.

POLYFUSOR* PHOSPHATES INJECTION

Presentation Polyfusor Phosphates Injection is a sterile, pyrogen-free solution of Sodium Phosphate and Potassium Acid Phosphate in Water for Injections prepared to British Pharmacopoeial standards. The solution is enclosed in disposable, semi-rigid containers of pure polyethylene.

<i>Concentrations w/v (%)</i>	<i>Approximate ion concentrations in millimoles per litre</i>
Sodium Phosphate 2.9	Sodium 162
Potassium Acid Phosphate 0.259	Phosphorus 100
	Potassium 19

Uses Polyfusor Phosphates Injection is given by intravenous infusion and is indicated in the treatment of severe hypercalcaemia, particularly that occurring in conjunction with cancer, hyperparathyroidism, hypervitaminosis-D, hyperthyroidism and sarcoidosis.

Dosage and administration The volume of phosphate solution given intravenously will depend upon the

requirements of the patient and the physician. No more than 100 millimoles of phosphorus should be given over 24 hours. The infusion must be given slowly.

Contra-indications, warnings, etc

Contra-indications: Intravenous phosphate therapy should not be used if the serum phosphorus concentration before therapy is raised.

Precautions: The patient must be carefully monitored. Rising blood urea nitrogen, elevation of serum phosphorus persisting more than 24 hours after therapy and normal or low serum calcium levels are among the contraindications to continued phosphate administration. Great caution should be undertaken during phosphate administration to patients with impaired renal function. In such patients 15–30 millimoles of phosphorus can be infused over 24 hours with constant monitoring of serum calcium and phosphorus.

Side-effects: Hypotension, tachycardia, pulmonary oedema, fever, hypocalcaemia and tetany, thrombophlebitis and calcification at infusion site.

Treatment of overdose: Discontinue infusion and give appropriate supportive treatment depending on electrolyte determination.

Recommended storage conditions: 2°C–25°C. The shelf life of Polyfusor Phosphates Injection is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Phosphates Injection is designed to meet the requirements of intravenous phosphate therapy. Prepared to an exceptionally high standard, the solution is supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, antioxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see Shelf-life). Polyfusor Phosphate Injection is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number 0014/0203.

POLYFUSOR* POTASSIUM CHLORIDE AND SODIUM CHLORIDE INJECTION

Presentation Polyfusor solution of Potassium Chloride and Sodium Chloride for intravenous infusion. Potassium Chloride 0.3% w/v and Sodium Chloride 0.9% w/v Injection BP in disposable containers of semi-rigid plastic. Each Polyfusor contains 500 ml of solution

Expressed in millimoles per litre, the electrolyte content of this solution is Sodium 150, Potassium 40 and Chloride 190.

Uses Polyfusor Potassium Chloride and Sodium Chloride Injection is given by intravenous infusion for the replacement of potassium loss.

Dosage and administration The amount of potassium administered by intravenous infusion depends upon the needs of the patient and the judgement of the physician; however, there are certain well-established principles concerned with potassium replacement.

1. The intravenous infusion of potassium solutions should be carried out slowly, i.e. at a rate not exceeding 20 millimoles of potassium per hour.

2. The concentration of potassium solutions given by intravenous infusion should not exceed 40 millimoles of potassium per litre.

3. An adult suffering from severe potassium loss may need up to 80 millimoles of intravenous potassium per day.

4. The administration of potassium (not necessarily by intravenous infusion) should be continued for at least three days after plasma potassium levels have returned to within normal levels.

Contra-indications, warnings, etc

Contra-indications: Addison's disease, adrenal insufficiency, acute or chronic renal disease, oliguria or anuria would preclude the giving of intravenous potassium.

Precautions: Before administering potassium by the intravenous route, it is essential to ensure that renal output is adequate and, by first giving a non-potassium hydrating solution, to ensure an adequate urine flow.

Side-effects: The adverse effects associated with the intravenous infusion of potassium solutions are almost invariably due to hyperkalaemia; these are listlessness, mental confusion, paraesthesia in extremities, weakness in the legs, hypotension, arrhythmias and, sometimes, cardiac arrest. Thrombosis of the selected vein is always a possibility with intravenous infusion.

Treatment of overdosage: Stop the infusion of potassium and, if there is persistent acidosis, replace with an infusion of sodium lactate or bicarbonate. Hyperkalaemia can be treated with an intravenous injection over a period of 145 minutes of Calcium Gluconate Injection BP.

Pharmaceutical precautions *Recommended storage conditions:* 2–25°C. The shelf-life of this product is 8 months.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon its inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded.

Legal category POM.

Package quantities Cartons of 10 × 500 ml.

Further information Polyfusor Potassium Chloride and Sodium Chloride Injection provides an immediately available source of intravenous potassium which obviates the inconvenient and somewhat hazardous use of

extemporaneously prepared potassium solutions. Other Polyfusor solutions for use in potassium replacement therapy include Potassium Chloride and Dextrose, Darrow's Solution, Hartmann's Solution and Ringer's Solution. These intravenous fluids are part of an extensive range of Polyfusor Solutions for Intravenous Infusion designed to meet almost every requirement in intravenous therapy. Polyfusor solutions are supplied in disposable, semi-rigid containers of a pure polyethylene free from plasticisers, stabilisers or other additives likely to leach out and contaminate the enclosed solution.

Product licence number 0014/5856.

POLYFUSOR* RINGER'S INJECTION

Presentation Polyfusor Ringer's Injection is a sterile, pyrogen free solution of Sodium Chloride, Potassium Chloride and Calcium Chloride in Water for Injections prepared to British Pharmacopoeial standards. The solution is enclosed in disposable, semi-rigid containers of pure polyethylene. The solution contains, in 1 litre, approximately 147 millimoles of sodium ions, 4 millimoles of potassium ions, 2 millimoles of calcium ions and 155 millimoles of chloride ions.

Uses Polyfusor Ringer's Injection is given by intravenous infusion and is used to correct the water and electrolyte depletion associated with dehydration.

Dosage and administration The volume and rate of infusion of Ringer's solution given by intravenous route will depend upon the requirements of the patient and the judgement of the physician.

Contra-indications, warnings, etc

Contra-indications: Intravenous Ringer's solution may be contra-indicated in patients with impaired renal or cardiac functions.

Precautions: Ringer's solution should not be administered rapidly or for prolonged periods. Rapid injection may cause sudden cardiac arrest or circulatory overloading.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdosage: Discontinue the infusion. The use of a diuretic may be indicated.

Pharmaceutical precautions *Recommended storage conditions:* 2°C–25°C. The shelf-life of Polyfusor Ringer's Injection is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Ringer's Injection is designed to meet the requirements of intravenous therapy. Prepared to an exceptionally high standard, the solutions are supplied in disposable, semi-rigid containers made from specially developed neutral plastic free from plasticisers, antioxidants and other additives

likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see shelf-life). Polyfusor Ringer's Injection is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number 0014/5253.

POLYFUSOR* SODIUM CHLORIDE INJECTIONS

Presentation Polyfusor Sodium Chloride Injections are sterile, pyrogen-free solutions of Sodium Chloride in Water for Injections prepared to British Pharmacopoeial standards. The solutions are enclosed in disposable, semi-rigid containers of pure polyethylene and are available in the following strengths:

Concentrations of sodium chloride w/w	Approximate ion concentration in millimoles per litre	
	Sodium	Chloride
0.18%	31	31
0.45%	77	77
0.9%	150	150
1.8%	308	308
2.7%	460	460
5.0%	855	855

Uses Polyfusor Sodium Chloride Injections are administered by intravenous infusion and are used mainly as an immediate measure to correct the water and electrolyte depletion associated with dehydration. Hypertonic solutions are used in the treatment of acute sodium deficiency and of water intoxication. Other uses include maintenance saline therapy in secondary dehydration and in haemorrhage, as a means of temporarily increasing blood volume.

Dosage and administration The volume, strength and rate of infusion of saline solutions given by the intravenous route will depend upon the requirements of the patient and the judgement of the physician. The effect of saline therapy on dehydration can often be assessed from relief of symptoms, observation of blood pressure and measurement of the volume and concentration of urine output.

Contra-indications, warnings, etc

Contra-indications: Intravenous saline solutions may be contra-indicated in patients with impaired renal or cardiac function.

Precautions: Saline solutions should not be administered rapidly or for prolonged periods particularly in infants and the elderly. A too rapid injection of hypertonic saline may cause sudden cardiac arrest or circulatory overloading.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdosage: An excess of sodium may be removed by the injection of a diuretic.

Pharmaceutical precautions Recommended storage conditions: 2–25°C. The shelf-life of Polyfusor Sodium Chloride Injections is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml. Carton of 10 × 1,000 ml.

Further information Polyfusor Sodium Chloride Injections provide a range of saline solutions designed to meet the many and varied requirements of intravenous saline therapy. Prepared to an exceptionally high standard, the solutions are supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, antioxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see 'Shelf-life'). Polyfusor Sodium Chloride Injections are part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

POLYFUSOR* SODIUM CHLORIDE AND DEXTROSE INJECTION

Presentation Polyfusor solutions of saline and dextrose are sterile, pyrogen-free solutions of Sodium Chloride and Anhydrous Dextrose in Water for Injection prepared to British Pharmacopoeial standards. The solutions are enclosed in disposable semi-rigid containers of pure polyethylene and are available in the following strengths:

Concentrations of saline and dextrose w/v (%)	Energy value in calories per litre	Approximate ion concentration in millimoles per litre			
		Sodium	Chloride	Anhydrous dextrose in grams per litre	
Sodium chloride 0.18 and dextrose 4	150	30	30	40	
Sodium chloride 0.45 and dextrose 2.5	94	77	77	25	
Sodium chloride 0.45 and dextrose 5	188	77	77	50	
Sodium chloride 0.9 and dextrose 5	188	154	154	50	

Uses Polyfusor Saline and Dextrose Solutions are given by intravenous infusion and are indicated for the treatment of dehydration with carbohydrate loss.

Dosage and administration The volume, strength and rate of infusion of saline and dextrose solutions given by intravenous infusion will depend upon the requirements of the patient and the judgement of the physician.

Contra-indications, warnings, etc

Contra-indications: Intravenous saline and dextrose solutions may be contra-indicated in patients with impaired renal and cardiac function.

Precautions: Saline and dextrose solutions should not be administered rapidly or for prolonged periods – particularly in infants and the elderly.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdose: Injection of a diuretic.

Pharmaceutical precautions Recommended storage conditions 2–25°C. The shelf-life of Polyfusor Sodium Chloride and Dextrose Solutions is 18 months. To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface, if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml. Carton of 10 × 1,000 ml.

Further information Polyfusor Sodium Chloride and Dextrose Solutions are designed to meet the many and varied requirements of intravenous therapy. Prepared to an exceptionally high standard, the solutions are supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, anti-oxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see 'shelf-life'). POLYFUSOR[®] SODIUM LACTATE INJECTION

Presentation Polyfusor Sodium Lactate Injection is a sterile, pyrogen-free solution of Sodium Lactate prepared

to British Pharmacopoeial Standards. The solution is enclosed in disposable, semi-rigid containers of pure polyethylene. The injection is one-sixth molar and contains, in 1 litre, approximately 167 millimoles of sodium ions and 167 millimoles of bicarbonate ions (as lactate).

Uses Polyfusor, Sodium Lactate Injection is given by intravenous infusion and is used to treat acidosis and to alkalis the urine.

Dosage and administration The volume and rate of infusion of sodium lactate solution given intravenously will depend upon the requirements of the patient. It should be remembered that the conversion of sodium lactate to bicarbonate in the liver takes one to two hours so that for immediate correction of acidosis an injection of sodium bicarbonate should be given. The rate of infusion should not exceed 300 ml/hour.

Contra-indications, warnings, etc

Contra-indications: Intravenous sodium lactate solutions are contra-indicated in patients with severe liver damage.

Precautions: Sodium lactate solutions should not be administered rapidly or for prolonged periods – particularly in infants and the elderly.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion.

Treatment of overdose: Discontinue the infusion and treat symptomatically.

Pharmaceutical precautions Recommended storage conditions: 2°C–25°C. The shelf-life of Polyfusor Sodium Lactate Injection is three years.

To prevent gross contamination of the outside surface of the Polyfusor, the outer envelope in which the Polyfusor is supplied should not be opened or removed until immediately before use.

Note: Immediately before use, the intact outer envelope in which the Polyfusor is supplied should be examined for moisture upon the inside surface; if moisture is observed, the integrity of the enclosed Polyfusor is suspect and it must be discarded. Unused solution remaining in a Polyfusor after use must also be discarded.

Legal category POM.

Package quantities Carton of 10 × 500 ml.

Further information Polyfusor Sodium Lactate Injection is designed to meet the requirements of intravenous sodium lactate therapy. Prepared to an exceptionally high standard, the solution is supplied in disposable, semi-rigid containers made from a specially developed neutral plastic free from plasticisers, anti-oxidants and other additives likely to leach out and contaminate the enclosed solution. The intact wall of the Polyfusor is impervious to micro-organisms and virtually impermeable to water vapour, thus ensuring the stability of the contents for very long periods under normal storage conditions (see shelf-life). Polyfusor Sodium Lactate Injection is part of the Polyfusor range of solutions for intravenous infusion – a range of solutions which, both in quality and extent, can meet the general and specific requirements of modern intravenous therapy.

Product licence number 0014/5248.

PROTHIADEN*

Presentation Prothiaden is Dothiepin Hydrochloride BP, an antidepressant of the tricyclic group.

Prothiaden is available as sugar-coated tablets, each containing 75 mg of Dothiepin Hydrochloride BP. The tablets are red in colour and bear the overprint 'P75' in white. It is also available in hard gelatin capsules, each containing 25 mg of Dothiepin Hydrochloride BP. The capsules are red/brown in colour with the overprint 'P25' in white.

Uses Prothiaden is indicated in the treatment of depression and the anxiety frequently associated with depressive illness.

Dosage and administration Prothiaden should be given in a dosage of 75 to 150 mg daily. The following dosage schemes are suggested:

Mild to moderate depression: 25 mg three times daily or 75 mg at night.

Moderate to severe depression: 150 mg daily in divided doses, or as a single dose at night. (If the latter regimen is adopted, it is preferable to use a smaller dose for the first few days.)

*In certain circumstances, i.e. in hospital use, Prothiaden has been given at dosages up to 225 mg daily.

No dietary restrictions are necessary during treatment with Prothiaden.

Contra-indications, warnings, etc Prothiaden has anticholinergic properties; therefore, it may precipitate urinary retention in susceptible individuals and its use should be avoided in patients with existing or potential urinary retention. Patients with closed-angle glaucoma should not be given Prothiaden and the occurrence of a painful red eye in a patient receiving the drug may indicate acute closed-angle glaucoma; this requires urgent treatment. In patients with chronic simple glaucoma, the risk of Prothiaden causing a rise in intraocular pressure is relatively small provided adequate anti-glaucoma therapy is being used. Caution is advised when treating epileptic patients and those with cardiovascular disorders.

From studies in animals, it was concluded that Prothiaden had no teratogenic effects in the species tested. Nevertheless, as with any relatively new drug, the use of Prothiaden during pregnancy should be avoided if possible.

Use with other drugs: Prothiaden should not be given concurrently with MAO inhibitors; nor should it be given within 14 days of ceasing treatment with an MAO inhibitor. Prothiaden may alter the pharmacological effect of some concurrently administered drugs; CNS depressants, including alcohol and narcotic analgesics, will be potentiated, as will the effects of adrenaline and noradrenaline (it should be borne in mind that some local anaesthetic preparations contain these sympathomimetics). The hypotensive effect of certain antihypertensive agents (e.g. bethanidine, debrisoquine, guanethidine) may be reduced.

Side-effects: Generally, the side-effects associated with Prothiaden have been mild and controlled by reduced dosage. The following have been reported – dryness of mouth, constipation, disturbed accommodation, lassitude, dizziness, orthostatic hypotension, palpitations, somnolence, tremor, headache.

Overdosage: The symptoms of overdosage with Prothiaden may include sedation, dry mouth, blurring of vision,

tachycardia, tremor, sweating, nausea, vomiting, confusion. The main dangers from overdosage arise from unconsciousness, convulsions, abnormal cardiac rhythms, hypotension and depression of respiration. The smallest dose of Prothiaden alone which resulted in the death of an adult was reported to be 0.75–1.0 g. The largest dose from which recovery took place was reported to be 5.0 g. In view of the many factors which influence the outcome of an overdose, these figures should not be considered in isolation.

Treatment of overdosage: Gastric lavage; in the unconscious patient or where the cough reflex is depressed, the lungs should be protected by a cuffed endotracheal tube. Repeated gastric/intestinal aspiration may remove drug and metabolites excreted into the gut via the bile. General support of the circulation with continuous ECG monitoring is advised. Abnormalities of cardiac rhythm and epileptic convulsions may occur and should be treated accordingly. Forced diuresis and haemodialysis are not recommended. Bedrest is advisable, even after clinical recovery.

Pharmaceutical precautions *Recommended storage conditions:* 5°C–20°C.

Legal category POM.

Package quantities *Prothiaden Tablets (75 mg):* 28, 500.

Prothiaden Capsules (25 mg): 100, 600.

Further information Prothiaden exhibits the psychopharmacological properties common to the tricyclic antidepressants. It is used in the treatment of depression and to relieve the anxiety often associated with depressive illness.

Prothiaden is used in a wide variety of depressive states and, in clinical trials, has been shown to be as effective as imipramine and more effective than amitriptyline.

While Prothiaden exhibits the side-effects associated with tricyclic antidepressants, these are usually mild and rarely severe enough to warrant withdrawal of the drug. Adults of all age-groups tolerate Prothiaden well, an important aspect of therapy when treating old people and outpatients.

Because it is so well tolerated, Prothiaden allows a considerable flexibility of regimen with the recommended dosage levels. In certain cases of depression, it has been found that the daily dosage of Prothiaden given as a single night-time dose is more effective and even better tolerated than the conventional divided daytime dosage. There is evidence that the single bed-time dose improves the sleep pattern of the depressed patient.

Because of the anxiolytic effect, the response to Prothiaden in patients suffering from anxiety and depression can often be observed within a few days after starting treatment. The effect of the drug upon the depressive component of the condition usually becomes apparent after seven to ten days.

STABILLIN* V-K ELIXIRS AND TABLETS

Presentation Stabillin V-K Elixirs '62.5', '125' and '250' are preparations of dry granules which, when reconstituted with the specified volume of water, provide elixirs (Phenoxymethylpenicillin Elixir BPC) containing

respectively the phenoxymethylpenicillin potassium equivalent to 62.5, 125 and 250 mg of phenoxymethylpenicillin in each 5 ml.

Stabillin V-K Tablets are Phenoxymethylpenicillin Tablets BP 250 mg.

Uses Stabillin V-K preparations are indicated in the treatment of mild to moderate infections due to susceptible Gram-positive organisms and to prevent the recurrence of rheumatic fever.

Dosage and administration Phenoxymethylpenicillin should be taken 30 minutes before food.

Adult: 0.5 to 1.5 g daily in divided doses.

Children 6 to 12 years: 250 mg every 6 hours.

Children 1 to 5 years: 125 mg every 6 hours.

Children up to 1 year: 62.5 mg every 6 hours.

As a prophylactic: 1 tablet twice daily for adults; adjust dosage for children.

Contra-indications, warnings, etc Stabillin V-K is contra-indicated in patients with a known sensitivity to penicillin and should be given with caution to those with a history of allergy. Phenoxymethylpenicillin is secreted in the milk and should be used with caution in nursing mothers as it may cause an allergic reaction in the offspring.

Side-effects: Penicillins given by mouth sometimes produce transient diarrhoea and, occasionally, nausea, heartburn and pruritus ani.

Treatment of overdose: Treatment is symptomatic, but is unlikely to be required.

Pharmaceutical precautions Stabillin V-K Elixir and the reconstituted Elixir should be stored in a cool place; the latter should be used within one week of preparation.

Legal category POM.

Package quantities

Stabillin V-K Elixirs: Bottle of granules to make 100 ml.

Stabillin V-K Tablets: Bottle of 500.

Further information Nil.

Stabillin V-K Tablets: 0014/5082

STERIFLEX* No. 1

Presentation Steriflex No. 1 is Sodium Chloride Injection BP and is a sterile, colourless preparation of normal saline for infusion in a clear, collapsible container. Sodium Chloride Injection BP contains 9 g sodium chloride per litre; sodium 150 millimoles per litre; chloride 150 millimoles per litre.

Indications Steriflex No. 1 is used in the treatment of dehydration to correct water and electrolyte depletion. It is useful in the treatment of acute sodium deficiency or water intoxication.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immo-

bilised, so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of thrombotic complications. Transfusion may be conducted under pressure, using the Martin or other suitable rotary pump, or by application of pressure to the Steriflex bag. The rate of administration and volume transfused will depend on the requirements of the individual patient. The correction of dehydration may be judged by relief of symptoms, restoration of blood pressure, reversal of haematoconcentration and the output of an adequate volume of urine of normal concentration.

Contra-indications, warnings, etc

Contra-indications: Patients with sodium overload. It is well known that this may occur with myocardial and renal damage, but it should also be appreciated that in the first five or six days after surgery or severe trauma there may be an inability to excrete unwanted sodium.

Precautions: Steriflex No. 1 is not suitable for protracted use unless there is heavy continued loss of electrolytes; even then, it should be used with care. In potassium-deficient patients administration of normal saline will increase potassium loss, so that if it is given, potassium supplements should also be given.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12-24 hours.

Treatment of overdose: An excess of sodium may be removed by the injection of a diuretic.

Pharmaceutical precautions **Storage:** Store at 2°C-25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10, in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0190.

STERIFLEX* No. 3

Presentation Steriflex No. 3 is a sterile, colourless preparation of Sodium Chloride and Dextrose Injection BP containing 5% of anhydrous dextrose in a clear, collapsible container and is intended for intravenous infusion. It contains 8 g per litre of sodium chloride, which represents 154 millimoles sodium and 154 millimoles chloride.

The anhydrous dextrose in Steriflex No. 3 provides 188 Calories per litre.

Indications Steriflex No. 3 is generally the standard solution for the correction of dehydration. In many conditions it is preferable to Sodium Chloride Injection BP (Steriflex No. 1), since the patient's carbohydrate store may be depleted. It is also of value in Addisonian crises and in dehydration with alkalosis.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised so there is less discomfort to the patient. If a leg

is selected this may increase the incidence of thrombotic complications.

Transfusions may be conducted under pressure, using the Martin or other rotary pump, or by application of pressure to the Steriflex bag.

The rate of administration and volume transfused will depend on the requirements of the individual patient. The correction of dehydration may be judged by relief of symptoms, restoration of blood pressure, reversal of haemoconcentration and the output of an adequate volume of urine of normal concentration. Where acidosis is a feature, correction is indicated by the disappearance of hyperventilation.

Contra-indications, warnings, etc

Contra-indications: Patients with sodium overload. It is well known that this may occur with myocardial and renal damage, but it should also be appreciated that in the first five or six days after surgery or severe trauma there may be an inability to excrete unwanted sodium. Steriflex No. 3 is not suitable for the treatment of insulin coma.

Precautions: Steriflex No. 3 is not suitable for protracted use unless there is a heavy continued loss of electrolytes; even then, it should be used with care. In potassium-deficient patients administration of normal saline solution will increase potassium loss, so that if it is given, potassium should also be given.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12–24 hours.

Treatment of overdosage: Injection of a diuretic.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10 in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0191.

STERIFLEX* No. 6 STERIFLEX* No. 7

Presentation Steriflex Nos. 6 and 7 are sterile, colourless preparations of dextrose in water and are Dextrose Injection BP 5% and Dextrose Injection BP 10%, respectively. They are in clear, collapsible containers and are intended for intravenous infusion.

Steriflex No. 6 contains 50 g of anhydrous dextrose per litre providing 188 Calories per litre.

Steriflex No. 7 contains 100 g of anhydrous dextrose per litre, providing 375 Calories per litre.

Indications Steriflex No. 6 is an isotonic solution used for maintenance therapy of dehydration after electrolyte depletion has been corrected. It is also useful as a source of water and carbohydrate for patients who have undergone abdominal surgery and who are not able to take oral fluids. It may be used for the treatment of insulin coma. Steriflex No. 7 has the same uses as Steriflex No. 6, but it provides more carbohydrate per litre and it is hypertonic.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised, so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of thrombotic complications.

Transfusion may be conducted under pressure, using the Martin or other suitable rotary pump, or by application of pressure to the Steriflex bag. The rate of administration and volume transfused will depend on the requirements of the individual patient.

Contra-indications, warnings, etc The administration of these solutions in diabetic patients must be conducted with caution.

Precautions: The infusion of these solutions should not be rapid or very prolonged. Large volumes of these solutions given too quickly may cause water intoxication, infusion over a long period can cause dehydration.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12–24 hours.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10. Steriflex Nos 6 and 7 are available in volumes of 500 ml and 1,000 ml.

Product licence numbers

No. 6 0014/0193

No. 7 0014/0194

STERIFLEX* No. 9

Presentation Steriflex No. 9 is a sterile, colourless preparation of Ringer's Solution for Injection in clear, collapsible containers. It is intended for intravenous infusion. Each litre contains sodium chloride 8.6 g potassium chloride 0.3 g and calcium chloride 0.48 g, that is sodium 147 millimoles per litre, potassium 4 millimoles per litre, calcium 2 millimoles per litre and chloride 155 millimoles per litre.

Indications Steriflex No. 9 is used as an intravenous infusion when an isotonic solution is needed for the treatment of dehydration with salt depletion and where there has been some loss of intracellular potassium.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised, so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of thrombotic complications. Transfusion may be conducted under pressure, using the Martin or other suitable rotary pump or by application of pressure to the Steriflex bag. The

rate of administration and volume transfused will depend on the requirements of the individual patient. The correction of dehydration may be judged by relief of symptoms, restoration of blood pressure, reversal of haemoconcentration and the output of an adequate volume of urine of normal concentration. Where acidosis is a feature, correction is indicated by the disappearance of hyperventilation.

Contra-indications, warnings, etc

Contra-indications: Patients with sodium overload. It is well known that this may occur with myocardial and renal damage, but it should also be appreciated that in the first five or six days after surgery or severe trauma there may be an inability to excrete unwanted sodium.

Precautions: Although Steriflex No. 9 contains potassium the quantity may be inadequate in the presence of intracellular potassium loss.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12–24 hours.

Treatment of overdosage: An excess of sodium may be removed by the injection of a diuretic.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10 in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0195.

STERIFLEX* No. 10

Presentation Steriflex No. 10 is a sterile, colourless preparation of Darrow's solution in a clear, collapsible container. It can be administered intravenously. Each litre of Steriflex No. 10 contains sodium chloride 4 g, potassium chloride 2.7 g, molar solution of sodium lactate 52.3 ml. The millimole concentrations per litre are sodium 121, potassium 35, chloride 103 bicarbonate (as lactate) 53.

Indications Metabolic acidosis with potassium deficiency. In cases of dehydration and shock there may be deficiency of intracellular potassium in the presence of normal or high serum potassium values. If dehydration is corrected without potassium supplementation hypokalaemia may occur.

Darrow's solution is frequently employed where acidosis is due to fluid loss from the alimentary tract, e.g. diarrhoea or excessive vomiting, or due to diabetic coma.

Dosage and administration Steriflex No. 10 should be used with caution. As with all solutions containing potassium, administration should be by slow intravenous infusion. Where there is established potassium depletion 3 litres per 24 hours will be required for adults. In infants and children a total of 80 ml per kg per 24 hours is a guide to maximum dosage.

Contra-indications, warnings, etc

Contra-indications: Potassium-containing solutions should not usually be given intravenously to correct

potassium depletion if potassium can be given by the oral route. Steriflex No. 10 should not be given to patients with cardiac arrhythmias.

Precautions: Particular care should be taken with patients who have oliguria or who have a plasma-sodium level below 120 millimoles per litre.

Side-effects: Untoward effects are likely to be due to hyperkalaemia and the first signs of this are shown in the electrocardiograph with the T wave becoming high and peaked. With increasing hyperkalaemia there is prolonged duration of the PR interval, leading to conduction defects, arrhythmias and possible cardiac arrest. Other symptoms include listlessness and mental confusion, numbness and tingling of the extremities, weakness of the legs, hypotension and, particularly in oliguric patients, an ascending flaccid paralysis.

Treatment of overdosage: When signs of hyperkalaemia are observed the infusion should be stopped and if acidosis persists replaced with a sodium bicarbonate or sodium lactate infusion. Hyperkalaemia may be treated by intravenous injection of 10 ml of calcium gluconate 10% solution with 50 ml or 50% dextrose solution and 10 units of soluble insulin.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the bag should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10, in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0196.

STERIFLEX* No. 11

Presentation Steriflex No. 11 is a sterile, colourless preparation of Compound Sodium Lactate Injection BP in a clear, collapsible container. It is also known as Hartmann's Solution for Injection and as Ringer-Lactate Solution for Injection. It can be administered intravenously. Each litre of Steriflex No. 11 contains sodium chloride 6.0 g potassium chloride 0.4 g, calcium chloride 0.27 g, sodium lactate equivalent to 2.4 ml lactic acid. The millimole concentrations per litre are sodium 131, potassium 5, calcium 2, chloride 111, and bicarbonate (as lactate) 29.

Indications Steriflex No. 11 is indicated for the treatment of metabolic acidosis and dehydration with acidosis. It may be used to expand extracellular fluids or restore extracellular electrolyte in practically all patients.

The treatment of diabetic coma.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of thrombotic complications. Transfusion may be conducted under pressure, using the Martin or other suitable rotary pump, or by application of pressure to the Steriflex

bag. The rate of administration and volume transfused will depend on the requirements of the individual patient.

Contra-indications, warnings, etc

Contra-indications: Patients with sodium overload. It is well known that this may occur with myocardial and renal damage, but it should also be appreciated that in the first five or six days after surgery or severe trauma there may be an inability to excrete unwanted sodium.

Lactate-containing solutions are contra-indicated in patients with liver diseases.

Precautions: Although Steriflex No. 11 provides potassium this is only enough to maintain the potassium content of extracellular fluid and would be quite inadequate for patients with severe potassium loss. Under these circumstances potassium supplements must be given. Lactate overdose in patients with heart disease may provoke arrhythmias and heart failure. ECG monitoring is recommended if administering Steriflex No. 11 to such patients.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12–24 hours.

Treatment of overdose: Where facilities exist for control of water and electrolyte balance overdose should not occur. In less than ideal situations accidental over-administration can be treated with intravenous injection of a diuretic.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10, in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0197.

STERIFLEX* No. 18

Presentation Steriflex No. 18 is Sodium Chloride and Dextrose Injection BP, a sterile, colourless preparation of sodium chloride 0.18% and anhydrous dextrose 4.0% in a clear, collapsible container. Each litre of Steriflex No. 18 contains sodium chloride 1.8 g and anhydrous dextrose 40 g. In each litre there are 30 millimoles of sodium, 30 millimoles of chloride and 150 calories.

Indications Steriflex No. 18 is probably the most generally used isotonic solution for maintenance intravenous fluid replacement. It can be employed for maintenance therapy. It can be used for the treatment of moderate-prolonged dehydration due to water-loss, but in severe cases 1 or 2 litres of Steriflex No. 1 (Sodium Chloride Injection BP) should be given before continuing with Steriflex No. 18.

Dosage and administration Intravenous infusions are preferably administered through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised, so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of

thrombotic complications. Transfusion may be conducted under pressure, using the Martin or other suitable rotary pump, or by application of pressure to the Steriflex bag. The rate of administration and volume transfused will depend on the requirement of the individual patient.

Contra-indications, warnings, etc

Contra-indications: Patients with sodium overload. It is well known that this may occur with myocardial and renal damage, but it should also be appreciated that in the first five or six days after surgery or severe trauma there may be an inability to excrete unwanted sodium.

Precautions: In patients with potassium deficiency it may be necessary to add potassium supplements.

It should not be used as initial therapy for patients in diabetic coma.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. If infusion is protracted then another vein should be selected after 12–24 hours.

Treatment of overdose: Injection of a diuretic.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10, in volumes of 500 ml and 1,000 ml.

Product licence number 0014/0192.

STERIFLEX* No. 20

STERIFLEX* No. 21

STERIFLEX* No. 22

Presentation Steriflex No. 20 is Laevulose Injection BP 10%, Steriflex No. 21 is Laevulose Injection BP 20% and Steriflex No. 22 is Laevulose Injection BP 40%. These are sterile, colourless solutions of laevulose in water, available in clear, collapsible containers.

Steriflex No. 20 contains laevulose 100 g per litre.

Steriflex No. 21 contains laevulose 200 g per litre.

Steriflex No. 22 contains laevulose 400 g per litre.

Steriflex Nos. 20, 21 and 22 are available in volumes of 500 ml only.

Indications Laevulose is a carbohydrate which can be utilised or converted into glycogen in the absence of insulin. It is indicated for conditions associated with carbohydrate deficiency. In acute alcohol poisoning laevulose injection accelerates the metabolism of alcohol.

Neonatal hypoglycaemia can be prevented in the neonates of diabetic mothers by intravenous infusion of 250–500 mg per kilo of laevulose to the mother two to three hours before delivery and then administration of Steriflex No. 20 through the infant's umbilical vein to a total dosage of 1 g laevulose per kg of body weight, two to three hours after delivery.

Dosage and administration The dosage and choice of the concentration of laevulose solution will depend on the condition and needs of the patient. All infusions should be slow and not exceed 800 mg per kilo body weight laevulose per hour.

Intravenous infusions are preferably administered

through a needle inserted into a superficial vein. However, in obese patients or young children this may prove difficult and then it will be necessary to cut down to the vein and insert a cannula. During intravenous infusion the limb should be immobilised, so there is less discomfort to the patient. If a leg vein is selected this may increase the incidence of thrombotic complications. The rate of administration and volume transfused will depend on the requirements of the individual patient.

Contra-indications, warnings, etc

Contra-indications: Laevulose injection should not be given to patients known to be intolerant of laevulose, or to patients with methyl alcohol poisoning as it enhances the oxidation of methyl alcohol to formaldehyde.

Laevulose injections should not be administered to patients in shock, with severe hepatic or renal disease or uncontrolled diabetes mellitus.

Precautions: Rapid injection of laevulose injection can cause thrombotic complications.

Side-effects: Thrombosis of the chosen vein is always a possibility with intravenous infusion. Reported side-

effects of large doses include facial flushing, epigastric pain and sweating.

Treatment of overdosage: Treatment consists of withdrawal of the infusion.

Pharmaceutical precautions *Storage:* Store at 2°C–25°C. The shelf-life is two years. The outer polythene bag is not sterilised but simply serves to protect the Steriflex bag. Before use the pack should be inspected and rejected if it is not clear or if the inner container is damaged.

Legal category POM.

Package quantities Steriflex is packed in containers of 10 in volumes of 500 ml.

ALPHA KERI* BATH OIL ▼

Presentation Alpha Keri Bath Oil is a clear colourless water dispersible anti-pruritic bath additive.

The product contains the following active ingredients: mineral oil (91.7%) and lanolin oil (3.0%).

Uses Alpha Keri effectively deposits a thin uniform emulsified film of oil over the skin, and thus retards evaporation of moisture, helps to relieve itching, lubricates and softens the skin.

Alpha Keri is valuable as an aid in the management of dry pruritic skin, especially in senile pruritis, ichthyosis and other dermatoses where dermal hydration is an important part of the therapy (as in the prevention of decubitus ulcer).

Alpha Keri Bath Oil is particularly suitable for infant bathing. The preparation also overcomes the problem of cleansing the skin in conditions where the use of soaps, soap substitutes and colloid or oat-meal baths prove irritating.

Dosage and administration Alpha Keri should always be either added to water or rubbed onto wet skin.

Because of its inherent cleansing properties it is not necessary to use soap with Alpha Keri.

Bath: Add 1–2 capfuls to the bath water. Soak for 10–20 minutes.

Sponge bath: Add 1–2 capfuls to a basin of warm water. Apply over entire body with a sponge or flannel.

Infant bath: Add $\frac{1}{2}$ capful to bath water.

Skin cleansing: Rub a small amount onto wet skin, rinse and pat dry.

Shower: Pour a small amount onto a wet sponge or flannel and rub onto wet skin, rinse and pat dry.

Alpha Keri may also be used in Whirlpools or Hubbard tanks, add 30 ml to every 450 litres of water.

Contra-indications, warnings, etc As Alpha Keri deposits a film of oil over the skin, special care should be taken to guard against slipping, especially in the bath or shower.

Alpha Keri contains lanolin oil and is therefore contra-indicated in those patients allergic to this ingredient.

Pharmaceutical precautions Nil.

Expiry date: 3 years from date of manufacture.

Legal category P.

Package quantities Alpha Keri Bath Oil is available in bottles containing 240 ml.

Further information Nil.

Product licence number 0125/0141.

AMIKIN*

Presentation *Amikin Injection:* Each multidose vial contains in 2 ml, amikacin sulphate equivalent to ami-

kacin activity 500 mg (500,000 international units). The vial contains methyl and propyl paraben.

Amikin Paediatric Injection: Each ampoule contains in 2 ml, amikacin sulphate equivalent to amikacin activity 100 mg (100,000 international units). The ampoule contains no preservatives.

Uses AMIKIN is a semi-synthetic, aminoglycoside antibiotic which is active against a broad spectrum of Gram-negative organisms, including pseudomonas and some Gram-positive organisms.

Sensitive Gram-negative organisms include: pseudomonas spp., *Escherichia coli*, indole-positive and indole-negative proteus spp., klebsiella-enterobacter-serratia spp., *Citrobacter freundii*, salmonella, shigella, mima-herellea and providencia spp.

Many strains of these Gram-negative organisms resistant to gentamicin and tobramycin show sensitivity to Amikin *in vitro*.

The principal Gram-positive organism sensitive to Amikin is *Staphylococcus aureus*, including methicillin-resistant strains. Amikin has some activity against other Gram-positive organisms including *Streptococcus pyogenes*, *Diplococcus pneumoniae*, and certain strains of enterococci.

Amikin is indicated in the short-term treatment of serious infections due to susceptible strains of Gram-negative bacteria, including pseudomonas species. Although Amikin is not the drug of choice for infections due to staphylococci, at times it may be indicated for the treatment of known or suspected staphylococcal disease. These situations include: the initiation of therapy for severe infections when the organisms suspected are either Gram-negative or staphylococcal, patients allergic to other antibiotics, and mixed staphylococcal/Gram-negative infections.

Therapy with Amikin may be instituted prior to obtaining the results of sensitivity testing.

Surgical procedures should be performed where indicated.

Dosage and administration At the recommended dosage level, uncomplicated infections due to sensitive organisms should respond to therapy within 24 to 48 hours.

If clinical response does not occur within three to five days, consideration should be given to alternative therapy.

Intramuscular or intravenous administration: For most infections the intramuscular route is preferred, but in life-threatening infections, or in patients in whom intramuscular injection is not feasible, the intravenous route, either slow bolus (two to three minutes) or infusion (30 minutes) may be used.

If required, suitable diluents for intravenous use are: normal saline, 5% dextrose in water, lactated Ringer's injection and lactated Ringer's injection with 5% dex-

trose. Once the product has been diluted the solution must be used as soon as possible and NOT STORED.

Adults and Children: 15 mg/kg/day in two equally divided doses (equivalent to 500 mg b.i.d. in adults):

Use of the 100 mg/2 ml strength is recommended for children for the accurate measurement of the appropriate dose.

Neonates and Premature Infants: An initial loading dose of 10 mg/kg followed by 15 mg/kg/day in two equally divided doses.

Sufficient extensive clinical use has not been achieved to enable firm dosage guidelines to be given in premature infants.

Life-threatening infections and/or those caused by pseudomonas: The adult dose may be increased to 500 mg every eight hours but should neither exceed 1.5 g/day nor be administered for a period longer than 10 days. A maximum total adult dose of 15 g should not be exceeded.

Urinary tract infections: (other than pseudomonal infections): 7.5 mg/kg/day in two equally divided doses (equivalent to 250 mg b.i.d. in adults). As the activity of amikacin is enhanced by increasing the pH, a urinary alkalising agent may be administered concurrently.

Impaired renal function: In patients with impaired renal function, the daily dose should be reduced and/or the intervals between doses increased to avoid accumulation of the drug. A suggested method for estimating dosage in patients with known or suspected diminished renal function is to multiply the serum creatinine concentration (in mg/100 ml) by 9 and to use the resulting figure as the interval in hours between doses.

Serum Creatinine Concentration (mg/100 ml)		Interval between Amikin doses of 7.5 mg/kg/IM (hours)
1.5	} X9=	13.5
2.0		18
2.5		22.5
3.0		27
3.5		31.5
4.0		36
4.5		40.5
5.0		45
5.5		49.5
6.0		54

As renal function may alter appreciably during therapy, the serum creatinine should be checked frequently and the dosage regimen modified as necessary.

Intraperitoneal use: Following exploration for established peritonitis, or after peritoneal contamination due to faecal spill during surgery, Amikin may be used as an irrigant after recovery from anaesthesia in concentrations of 0.25% (2.5 mg/ml). It may also be instilled into the wound at closure. If instillation is desired in adults, a single dose of 500 mg is diluted in 20 ml of sterile distilled water and may be instilled through a polyethylene catheter sutured into the wound at closure. If possible, instillation should be postponed until the patient has fully recovered from the effects of anaesthesia and muscle-relaxing drugs.

Other routes of administration: Amikin in concentrations of 0.25% (2.5 mg/ml) may be used satisfactorily as an

irrigating solution in abscess cavities, the pleural space, the peritoneum and the cerebral ventricles.

Only the paediatric dosage form (which contains no preservatives) should be used for intraventricular administration.

Contra-indications, warnings, etc Patients should be well hydrated during Amikin therapy.

In patients with impaired renal function or diminished glomerular filtration, Amikin should be used cautiously. In such patients, renal function should be assessed by the usual methods prior to therapy and periodically during therapy. Daily doses should be reduced and/or the interval between doses lengthened in accordance with serum creatinine concentrations to avoid accumulation of abnormally high blood levels and to minimise the risk of ototoxicity.

If therapy is expected to last seven days or more in patients with renal impairment, or 10 days in other patients, a pre-treatment audiogram should be obtained and repeated during therapy. Amikin therapy should be stopped if tinnitus or subjective hearing loss develops, or if follow-up audiograms show significant loss of high-frequency response.

As with other aminoglycosides, ototoxicity and/or nephrotoxicity can result from the use of Amikin; precautions on dosage and adequate hydration should be observed.

If signs of renal irritation appear (such as albumin, casts, red or white blood cells), hydration should be increased and a reduction in dosage may be desirable. These findings usually disappear when treatment is completed. However, if azotaemia or a progressive decrease in urine output occurs, treatment should be stopped.

The use of Amikin in patients with a history of allergy to aminoglycosides or in patients who may have subclinical renal or eighth nerve damage induced by prior administration of nephrotoxic and/or ototoxic agents such as streptomycin, dihydrostreptomycin, gentamicin, tobramycin, kanamycin, bekanamycin, neomycin, polymyxin B, colistin, cephaloridine, or viomycin should be considered with caution, as toxicity may be additive. In these patients Amikin should be used only if, in the opinion of the physician, therapeutic advantages outweigh the potential risks.

The risk of ototoxicity is increased when Amikin is used in conjunction with rapidly acting diuretic drugs, particularly when the diuretic is administered intravenously. Such agents include frusemide and ethacrynic acid, which is itself an ototoxic agent. Irreversible deafness may result.

The intraperitoneal use of Amikin is not recommended in young children or in patients under the influence of anaesthetics or muscle-relaxing drugs (including ether, halothane, d-tubocurarine, succinylcholine and decamethonium) as neuromuscular blockade and consequent respiratory depression may occur.

Pregnancy: The safety of Amikin in pregnancy has not yet been established.

Side-effects: When the recommended precautions and dosages are followed the incidence of toxic reactions, such as tinnitus, vertigo, and partial reversible or irreversible deafness, skin rash, drug fever, headache, paraesthesia, nausea and vomiting is low. Urinary signs of renal irritation (albumin, casts, and red or white cells), azotaemia and oliguria have been reported.

Pharmaceutical precautions At times, Amikin may

be indicated as concurrent therapy with other antibacterial agents in mixed or superinfections. In such instances, Amikin should not be physically mixed with other antibacterial agents in syringes, infusion bottles or any other equipment. Each agent should be administered separately.

AMIKIN, as supplied, is stable at 25°C for a period of three years. At times, the solution may darken from colourless to a pale yellow but this does not indicate a loss in potency.

Expiry Date: 36 months from date of manufacture.

Legal category POM.

Package quantities *Amikin Injection:* 2 ml vials packed in cartons of 5.

Amikin Paediatric Injection: 2 ml ampoules packed in cartons of 5.

Further information Amikin is rapidly absorbed after intramuscular injection. Peak serum levels of approximately 11 mcg/ml and 23 mcg/ml are reached one hour after i.m. doses of 250 mg and 500 mg respectively. Levels 10 hours after injection are of the order of 0.3 mcg/ml and 2.1 mcg/ml respectively.

Twenty per cent or less is bound to serum protein and serum concentrations remain in the bactericidal range for sensitive organisms for 10 to 12 hours.

Amikin diffuses readily through extracellular fluids and is excreted in the urine unchanged, primarily by glomerular filtration. Half-life in individuals with normal renal functions is two to three hours.

Following intramuscular administration of a 250 mg dose, about 65% is excreted in six hours and 91% within 24 hours. The urinary concentrations average 563 mcg/ml in the first six hours and 163 mcg/ml over 6 to 12 hours. Mean urine concentrations after a 500 mg i.m. dose average 832 mcg/ml in the first six hours.

Single doses of 500 mg administered to normal adults as an intravenous infusion over a period of 30 minutes produce a mean peak serum concentration of 38 mcg/ml at the end of the infusion. Repeated infusions do not produce drug accumulation.

Amikin has been found in cerebrospinal fluid, pleural fluid, amniotic fluid and in the peritoneal cavity following parenteral administration.

Paediatric Injection 100 mg/2 ml 0125/0087
Injection 500 mg/2 ml 0125/0092

BiCNU* ▼

Presentation *BiCNU Injection:* each package contains a 30 ml vial containing 100 mg carmustine and a 5 ml vial containing 3 ml sterile ethanol diluent.

Uses BiCNU is indicated as palliative therapy as a single agent or in established combination therapy with other approved chemotherapeutic agents in the following:

1. Brain tumours – Glioblastoma, brainstem glioma, medulloblastoma, astrocytoma, ependymoma, and metastatic brain tumours.
2. Multiple myeloma – In combination with prednisone.
3. Hodgkin's Disease – As secondary therapy in combination with other approved drugs in patients who relapse while being treated with primary therapy, or who fail to respond to primary therapy.

4. Non-Hodgkin's lymphomas – As secondary therapy in combination with other approved drugs in patients who relapse while being treated with primary therapy, or who fail to respond to primary therapy.

5. BiCNU has also been used in the palliative management of other cancers such as malignant melanoma.

Dosage and administration

Intravenous administration: The recommended dose of BiCNU as single agent in previously untreated patients is 200 mg/m² intravenously every six weeks. This may be given as a single dose or divided into daily injections such as 100 mg/m² on two successive days.

When BiCNU is used in combination with other myelosuppressive drugs or in patients in whom bone marrow reserve is depleted the doses should be adjusted accordingly.

A repeat course of BiCNU should not be given until circulating blood elements have returned to acceptable levels (platelets above 100,000/mm³; leucocytes above 4,000/mm³) and this is usually in six weeks. Blood counts should be monitored frequently and repeat courses should not be given before six weeks because of delayed toxicity.

Doses subsequent to the initial dose should be adjusted according to the haematological response of the patient to the preceding dose. The following schedule is suggested as a guide to dosage adjustment.

<i>Nadir after Prior Dose</i>		<i>Percentage of prior dose to be given</i>
<i>Leucocytes (/mm³)</i>	<i>Platelets (/mm³)</i>	
> 4000	> 100,000	100
3000–3999	75,000–99,999	100
2000–2999	25,000–74,999	70
< 2000	< 25,000	50

Contra-indications, warnings, etc BiCNU should not be given to individuals who have demonstrated a previous hypersensitivity to it.

BiCNU should not be given to individuals with decreased circulating platelets, leucocytes, or erythrocytes either from previous chemotherapy or other causes.

BiCNU should not normally be administered to patients who are pregnant or mothers who are breast-feeding.

Safe use in pregnancy has not been established and therefore the benefit to risk of toxicity must be carefully weighed. BiCNU is embryotoxic and teratogenic in rats and embryotoxic in rabbits at dose levels equivalent to the human dose. BiCNU also affects fertility in male rats at doses somewhat higher than the human dose.

BiCNU is carcinogenic in rats and mice, producing a marked increase in tumour incidence in doses approximating those employed clinically.

BiCNU should be administered by individuals experienced in antineoplastic therapy. Since delayed bone marrow toxicity is the major toxicity, complete blood counts should be monitored frequently for at least six weeks after a dose. Repeat doses of BiCNU should not be given more frequently than every six weeks. The bone marrow toxicity of BiCNU is cumulative and therefore dosage adjustment must be considered on the basis of nadir blood counts from prior dose (see Dosage Adjustment Table under Dosage).

It is recommended that liver function tests also be monitored.

Adverse reactions: Haematological: The most frequent and most serious toxicity of BiCNU is delayed myelosuppression. It usually occurs four to six weeks after drug administration and is dose-related. Platelet nadirs occur at four to five weeks; leucocyte nadirs occur at five to six weeks post therapy. Thrombocytopenia is generally more severe than leucopenia. However both may be dose limiting toxicities. Anaemia also occurs, but is generally less severe.

Gastro-intestinal: Nausea and vomiting after i.v. administration of BiCNU are noted frequently. This reaction appears within two hours of dosing, usually lasting four to six hours and is dose-related. Prior administration of anti-emetics is effective in diminishing and sometimes preventing this side-effect.

Hepatic: When high doses of BiCNU have been employed, a reversible type of hepatic toxicity, manifested by increased transaminase, alkaline phosphatase and bilirubin levels, has been reported in a small percentage of patients.

Local: Burning at the site of injection is common but true thrombosis is rare.

Other: Rapid i.v. infusion of BiCNU may produce intense flushing of the skin and suffusion of the conjunctiva within two hours, lasting about four hours.

Pharmaceutical precautions *Preparation of intravenous solution:* Dissolve BiCNU with 3 ml of the supplied sterile diluent (absolute ethanol) and then aseptically add 27 ml of sterile water for injection to the alcohol solution. Each ml of the resulting solution will contain 3.3 mg of BiCNU in 10% ethanol and has a pH of 5.6 to 6.0.

Reconstitution as recommended results in a clear colourless solution which may be further diluted with sodium chloride for injection, or 5% dextrose for injection.

The reconstituted solution must be given intravenously and should be administered by i.v. drip over a one- to two-hour period. Injection of BiCNU over shorter periods of time may produce intense pain and burning at the site of injection.

Important note: The lyophilised dosage formulation contains no preservatives and is not intended as a multiple dose vial.

Stability: Unopened vials of the dry powder must be stored in a refrigerator (2°C–8°C). The recommended storage of unopened vials prevents significant decomposition for at least two years.

After reconstitution as recommended, decomposition of BiCNU at room temperature is linear with time. After three hours, approximately 6% of the solution has decomposed and after six hours, approximately 8%. Refrigeration (4°C) of the reconstituted BiCNU significantly increases the stability of the solution. After 24 hours, when protected from light, there is only 4% decomposition. Further dilution of the reconstituted solution with 500 ml of sodium chloride for injection or 5% dextrose for injection, results in a solution which is stable for 48 hours when protected from light and refrigerated.

Important note: BiCNU has a low melting point (approximately 27°C or 80.6°F). Exposure of the drug to this temperature or above will cause the drug to liquefy and appear as an oil film in the bottom of the vials. This is a sign of decomposition and vials should be discarded.

Legal category POM.

Package quantities BiCNU Injection packed in cartons of 10 units, each unit consisting of one vial of carmustine 100 mg and one vial of sterile absolute alcohol 3 ml.

Further information BiCNU alkylates DNA and RNA and has also been shown to inhibit several enzymes by carbamoylation of amino acids in proteins.

Intravenously administered BiCNU is rapidly degraded, with no intact drug detectable after 15 minutes. However, in studies with C¹⁴ labelled drug, prolonged levels of the isotope were observed in the plasma and tissue, probably representing radioactive fragments of the parent compound.

It is thought that the antineoplastic and toxic activities of BiCNU may be due to metabolites. Approximately 60 to 70% of a total dose is excreted in the urine in 96 hours and about 10% as respiratory CO₂. The fate of the remainder is undetermined.

Because of the high lipid solubility and the relative lack of ionisation at a physiological pH, BiCNU crosses the blood brain barrier.

Levels of radioactivity in the CSF are at least 50% higher than those measured concurrently in plasma.

Product licence number 0125/0108.

CeeNU* ▼

Presentation Blue-blue capsules printed BRISTOL 3030, containing 10 mg lomustine.

Blue-green capsules printed BRISTOL 3031, containing 40 mg lomustine.

Green-green capsules printed BRISTOL 3032, containing 100 mg lomustine.

Uses CeeNU is indicated as adjuvant therapy to surgery and radiotherapy or in combination with other chemotherapeutic agents in the following:

1. Brain tumours – Both primary and metastatic, in patients who have already undergone appropriate surgical procedures.

2. Lung cancer – Squamous cell, anaplastic large cell and adenocarcinoma. CeeNU has been used alone and in combination with appropriate antineoplastic drugs such as cyclophosphamide.

3. Malignant melanoma – Alone or in combination with other active drugs such as vincristine.

4. Hodgkin's Disease – Alone or in combination with other active drugs.

CeeNU has been used in renal cell carcinoma, although the response rate is low in this resistant cancer. Responses have also been observed with non-Hodgkin's lymphoma, ovarian and pancreatic carcinoma, but data are insufficient to make a definite recommendation.

Dosage and administration The recommended dose of CeeNU is 130 mg/m² as a single dose by mouth every six weeks.

In individuals with compromised bone marrow function, because of either disease or prior therapy, the dose should be reduced to 100 mg/m² every six weeks. A repeat course of CeeNU may be given when circulating blood elements have returned to acceptable levels (platelets above 100,000/mm³; leucocytes above 4,000/mm³) and this is usually in six weeks. Blood counts should be monitored frequently and repeat

courses should not be given before six weeks as haematological toxicity is delayed and cumulative.

Doses subsequent to the initial dose should be adjusted according to the haematological response of the patient to the preceding dose. The following schedule is suggested as a guide to dosage adjustment.

Nadir after Prior Dose		Percentage of prior dose to be given
Leucocytes (/mm ³)	Platelets (/mm ³)	
> 4,000	> 100,000	100
3,000-3999	75,000-99,999	100
2,000-2,999	25,000-74,999	70
< 2,000	< 25,000	50

When CeeNU is used in combination with myelosuppressive drugs, doses should be adjusted accordingly. It is recommended that liver and renal function be monitored frequently as well as blood counts.

Contra-indications, warnings, etc

Contra-indications: CeeNU should not be given to individuals who have demonstrated a previous hypersensitivity to it.

Warnings: CeeNU should be given with caution to individuals with depressed circulating platelets, leucocytes or erythrocytes.

Safe use in pregnancy has not been established. CeeNU is embryotoxic and teratogenic in rats and embryotoxic in rabbits at dose levels equivalent to the human dose. CeeNU also affects fertility in male rats at doses somewhat higher than the human dose. CeeNU is carcinogenic in rats and mice, producing a marked increase in tumour incidence in doses approximating to those employed clinically.

CeeNU should not normally be administered to patients who are pregnant or mothers who are breastfeeding.

Precautions: Since the major toxicity is delayed bone marrow suppression, blood counts should be monitored weekly for at least six weeks after a dose. At the recommended dosage, courses of CeeNU should not be given more frequently than every six weeks.

Adverse reactions: Haematological: Thrombocytopenia occurs at about four weeks after a dose of CeeNU and persists for one to two weeks.

Leucopenia occurs about six weeks after a dose of CeeNU and persists for one to two weeks.

CeeNU may produce cumulative myelosuppression, manifested by more depressed indices or longer duration of suppression after repeated doses.

Anaemia has been reported infrequently.

Gastro-intestinal: Nausea and vomiting may occur three to six hours after an oral dose and usually last less than 24 hours. The frequency and duration may be reduced by use of anti-emetics prior to dosing and by the administration of CeeNU to fasting patients.

Other toxicities: Stomatitis, alopecia and hepatic toxicity (manifested by transient reversible elevation of liver function tests) have been reported infrequently.

Neurological reactions such as disorientation, lethargy, ataxia and dysarthria have been noted in some patients receiving CeeNU.

Overdosage: In the case of overdosage, the patient should be treated symptomatically.

Pharmaceutical precautions Correct dosage may require the administration of more than one strength of capsule. The patient should be advised of the necessity of this to enhance compliance. CeeNU capsules should be stored at room temperature in a well closed container.

Expiry date: Three years from date of manufacture.

Legal category POM.

Package quantities CeeNU capsules are available in three strengths: 10 mg, 40 mg and 100 mg, each of which are supplied in screw-capped bottles containing 20 capsules.

Further information It is generally agreed that CeeNU acts as an alkylating agent, but as with other nitrosoureas, it may also inhibit several key enzymatic processes.

Following oral administration of radioactive CeeNU at doses ranging from 30 mg to 100 mg, about half the dosed radioactivity is excreted within 24 hours. The serum half-life of the drug and/or metabolites ranges from 16 hours to two days. Tissue levels are comparable to plasma levels at 15 minutes after intravenous administration.

Because of high lipid solubility and relative lack of ionisation at physiological pH, CeeNU crosses the blood brain barrier and radioactivity levels in the CSF are 50% or greater than those measured concurrently in plasma.

DEFENCIN CP*

Presentation Hard gelatin capsules (No. 4), having a pale pink cap and red body. Each capsule is coded Defencin VS40 and contains the equivalent of 40 mg isoxsuprine, in graded release form.

Uses Cerebral vascular disease including cerebral arteriosclerosis, cerebral vasospasm, and cerebral ischaemia.

Peripheral vascular disease including peripheral arteriosclerosis, Buerger's disease, Raynaud's disease and peripheral vasospasm.

Dosage and administration **Adults:** 1 capsule every 12 hours.

Children: The product is not intended for administration to children.

Contra-indications, warnings, etc Recent arterial bleeding or immediately post-partum.

Defencin is extremely well tolerated and side-effects are rare. Occasional hypotension, tachycardia, flushing or palpitations have been reported with preparations of isoxsuprine, but these are controlled by a reduction in dose.

Pharmaceutical precautions To be stored in a cool dry place, at temperatures generally not exceeding 20°C, protected from light.

Expiry date – 36 months from date of manufacture.

Legal category P.

Package quantities Blister strip of 14 capsules with 4 strips to a carton.

Further information Isoxsuprine (Defencin) is a myovascular relaxant which acts directly on vascular smooth muscle.

Product licence number 0125/0074.

KANTREX® CAPSULES

Presentation Yellow capsules containing kanamycin sulphate BP equivalent to kanamycin activity 250 mg.

Uses Kantrex is indicated in the treatment of the following, when due to sensitive organisms: Infections of the gastro-intestinal tract including Sonne dysentery and infectious diarrhoeas. Pre-operative bowel sterilisation. Elimination of carrier states. Adjunctive in the treatment of hepatic coma.

Dosage and administration *Adults: Intestinal infections:* 1–2 g per day in 4 divided doses for five to seven days.

Pre-operative bowel sterilisation: 1 g every hour for four hours followed by 1 g every six hours for 36–72 hours. The duration of therapy depends on the condition of the patient and the amount of concurrent mechanical cleansing.

Hepatic coma: 8–12 g per day in divided doses.

Children: Dosage appropriately reduced according to age and weight.

Contra-indications, warnings, etc The oral administration of Kantrex is remarkably free from side-effects. Overgrowth of yeasts is much less common than with neomycin. If superinfection occurs appropriate therapy should be instituted and the administration of Kantrex discontinued if necessary.

Although negligible amounts of kanamycin are absorbed through intact intestinal mucosa, the possibility of increased absorption from ulcerated or denuded areas should be considered.

Pharmaceutical precautions Expiry date – 48 months from date of manufacture.

There are no special directions for storage.

Legal category POM.

Package quantities Containers of 100 capsules.

Further information Kantrex (kanamycin sulphate) is a broad-spectrum antibiotic with a wide bactericidal action against pathogenic inhabitants of the gastro-intestinal tract.

When administered orally kanamycin is poorly absorbed from the gastro-intestinal tract. After oral administration of 6 g daily the serum activity is less than 2 mcg/ml.

Product licence number 0125/5002.

KANTREX® INJECTION

(For Single Dose Use Only.)

Presentation Kantrex Injection 1.0 g contains in 3 ml; kanamycin sulphate equivalent to kanamycin activity 1.0 g (1,000,000 international units).

Uses Kantrex is indicated in the treatment of the following infections due to susceptible organisms.

Respiratory tract infections (including tuberculosis). Genito-urinary tract infections (including gonorrhoea). Skin and soft-tissue infections. Bone and joint infections. Meningitis. Septicaemia and bacteraemia. Peritonitis. Post surgical infections.

Dosage and administration General recommendations:

Intramuscular route: For adults: 1 g administered daily in divided doses of 0.5 g every twelve hours or 0.25 g every six hours (15 mg/kg per day). The daily dose should not exceed 1.5 g even for heavier patients.

For children under 50 kg: 15 mg/kg per day in 2 divided doses every 12 hours. For premature infants weighing less than 2.5 kg, the recommended dose is 7.5–10 mg/kg per day.

Gonorrhoea: A single dose of 2.0 g is a most effective regimen.

Tuberculosis: 1–2 g should be given two or three times a week. Treatment may be prolonged for up to three or four months. In these cases a careful watch should be maintained against the possibility of ototoxicity developing.

Intravenous route: Only recommended when the intramuscular route is not feasible.

Adults and children: 15 mg per kg per day in 2 divided doses diluted with sterile, pyrogen-free, normal saline or 5% dextrose in water (or normal saline) by slow intravenous infusion (60–80 drops per minute). The preferred concentration of Kantrex for intravenous use is 0.25% (2.5 mg/ml).

Intraperitoneal route (following exploration for established peritonitis or after peritoneal contamination due to faecal spill during surgery):

Adults: 0.5 g Kantrex in 20 ml water for injection into the peritoneal cavity through a polyethylene catheter sutured into the wound at closure.

(It is generally recommended that instillation of Kantrex should be postponed until the patient has recovered from the effects of anaesthesia if muscle-relaxing drugs have been used.)

Aerosol treatment: 250 mg two to four times a day. Withdraw 0.75 ml from a 1 g vial, and dilute with 3.25 ml normal saline and nebulise. A bronchodilator and mucolytic can be included in the aerosol procedure.

Other routes of administration: Kantrex in concentrations of 0.25% has been used satisfactorily as an irrigating solution in abscess cavities, pleural spaces, peritoneal and ventricular cavities. Although solutions of 0.25% or less have been administered intrathecally (up to 25 mg in 10 ml during 24 hours) the intramuscular administration of 7.5 mg/kg Kantrex in infants with bacterial meningitis has produced peak mean CSF levels of 9 mcg/ml. This was approximately twice the concentration produced in normal infants and exceeds the MIC of many pathogenic organisms.

In patients with renal disease and impaired renal function, the daily dosage should be reduced in accordance with the serum creatinine concentration. A suitable dosage scheme is outlined below:

Serum creatinine concentration		Interval between Kanamycin doses of 7.5 mg/kg/IM (hours)
(mmol/litre)	(mg/100 ml)	
140	1.5	13½
180	2.0	18
230	2.5	22½
270	3.0	27
320	3.5	31½
360	4.0	36
410	4.5	40½
450	5.0	45
500	5.5	49½
550	6.0	54

This formula is based on two facts which have been demonstrated.

1. The half-life of Kantrex, in hours, is approximately three times the mg/100 ml serum creatinine concentration.

2. Dosage intervals of every third half-life, using a recommended intramuscular dose of Kantrex, will provide adequate antimicrobial levels and minimise risk of toxic drug accumulation.

Consequently, the appropriate Kantrex dosage interval in hours can be estimated by multiplying the serum creatinine in mg/100 ml by 9 or by dividing its value in mmol/litre by 10 as shown in the diagram above.

This method of adjusting the dose enables the serum concentration to be maintained at the correct non-toxic level despite impaired renal function and is an important measure in preventing side-effects.

Contra-indications, warnings, etc Patients should be well hydrated during kanamycin therapy.

In patients with renal disease and impaired renal function, the daily dosage should be reduced in accordance with the serum creatinine concentration.

Kanamycin therapy should be stopped if tinnitus, a sensation of fullness of the ears or subjective hearing loss develops, or if follow-up audiograms show significant loss of high-frequency response.

Use of antibiotics may occasionally result in overgrowth of non-sensitive organisms. If superinfection does appear, treatment should be discontinued and appropriate therapy instituted.

The incidence of side-reactions to kanamycin is low. In well-hydrated patients under 45 years of age with normal kidney function receiving the recommended dosage, the risk of ototoxic reactions is negligible. In cases of impaired kidney function where excretion of the drug may be affected, adjusting the dose in accordance with the creatinine clearance level will minimise any accumulation of kanamycin and reduce the risk of ototoxic reactions. However, older patients and patients receiving a total dose of more than 20 g of kanamycin should be carefully observed for signs of eighth-nerve involvement.

Urinary signs of renal irritation (casts, white or red cells and albumin) may appear, particularly in toxic, poorly hydrated patients. Where the renal function is not impaired, however, and there is no evidence of nitrogen retention, these signs are reversible and are not indications for stopping therapy.

Skin eruptions during therapy have rarely been noted and their relationship to Kantrex has not been established.

Liver, haematopoietic or cardiovascular toxicity has not been observed.

Pharmaceutical precautions Kantrex Injection retains its potency for at least three years from date of manufacture. No refrigeration or special storage facilities are necessary. Slight discoloration of the solution may occasionally be noticed. This discoloration does not affect the potency, tolerance or therapeutic effectiveness of the product.

Diluents – Sterile Normal Saline or 5% dextrose in water (or normal saline).

Kantrex should not be physically mixed with other antimicrobial agents.

Expiry date – 36 months from date of manufacture.

For single dose use only.

Legal category POM.

Package quantities Kantrex is supplied in rubber-capped vials as a ready-to-use sterile aqueous solution.

Kantrex 1.0 g (1,000,000 international units) in 3 ml.

Further information Nil.

Product licence number

Kantrex 1.0 g 0125/5004.

NEOPLATIN* ▼

Presentation *Neoplatin injection*: Vials containing 10 mg and 50 mg cisplatin (cis-diamminedichloroplatinum).

Uses Neoplatin is indicated as palliative therapy to be employed in addition to other modalities, or in established combination therapy with other approved chemotherapeutic agents in the management of neoplastic diseases, especially:

Metastatic Testicular Tumours – In patients who have already received appropriate surgical and/or radiotherapeutic procedures. The combination of Neoplatin, bleomycin and vinblastine has been reported to be highly effective. Other combinations have also been reported to be active.

Metastatic Ovarian Tumours – As secondary therapy in patients refractory to standard chemotherapy.

Dosage and administration

Single agent therapy: The recommended dose of Neoplatin in adults and children is 50–120 mg/m² as a single i.v. dose every three to four weeks, or 15–20 mg/m² i.v. daily for five days every three to four weeks.

Combination therapy: In general, current multiple drug treatment schedules including Neoplatin employ lower doses ranging from 20 mg/m² upwards, administered i.v. every three to four weeks.

Pretreatment hydration with 1–2 litres of fluid infused for 8–12 hours prior to a Neoplatin dose is recommended in order to initiate diuresis.

Reconstitute the 10 mg vial contents with 10 ml, and the 50 mg vial contents with 50 ml of Sterile Water for Injection PhEur. The resulting drug solution is then administered in 2 litres of a suitable diluent such as 0.9% saline, or a dextrose-saline solution. It is recommended that administration should be over a six–eight hour period. Diuresis may be aided by the addition to the infusion solution of 37.5 g mannitol.

Adequate hydration and urinary output must be maintained during the 24 hours following infusion.

A repeat course of Neoplatin should not be given until the serum creatinine is below 1.5 mg/100 ml (130 µmol/l) and/or the blood urea below 55 mg/100 ml (9 mmol/l). A repeat course should not be given until circulating blood elements are at an acceptable level. Subsequent doses of Neoplatin should not be given until an audiometric analysis indicates that auditory acuity is within normal limits.

Contra-indications, warnings, etc Neoplatin induces nephrotoxicity, myelosuppression, neurotoxicity and ototoxicity which may be additive to pre-existing dysfunctions. Consequently, the use of Neoplatin in patients with hearing or renal impairment or depressed bone marrow function may be associated with increased toxicities. Such conditions represent relative contra-indications.

Neoplatin is contra-indicated in patients with a history of hypersensitivity to Neoplatin or other platinum-containing compounds.

Warnings: Neoplatin produces cumulative nephrotoxicity. The serum creatinine, BUN or creatinine clearance should be measured prior to initiating therapy, and prior to each subsequent course.

Anaphylactic-like reactions to Neoplatin have been reported. These reactions have occurred within minutes of administration to patients with prior exposure to Neoplatin and have been alleviated by administration of adrenaline, steroids and antihistamines.

Safe use in pregnancy has not been established. This product should not normally be administered to patients who are pregnant or to mothers who are breast-feeding. Neoplatin is mutagenic in bacteria and produces chromosome aberrations in animal cells in tissue culture. Although carcinogenicity and teratogenicity have not been established, compounds with similar mechanisms of action and mutagenicity have been reported to be carcinogenic.

The influence of Neoplatin on human reproduction has not been determined. Neoplatin therapy might have an anti-fertility effect.

Precautions: Neoplatin should be administered by individuals experienced in the use of antineoplastic therapy.

Neurotoxicity appears to be cumulative. Prior to each course, the absence of symptoms of peripheral neuropathy should be established. (See Adverse Reactions.)

Since renal toxicity is cumulative, measurements of BUN, serum creatinine or creatinine clearance should be performed prior to initiating therapy and prior to each subsequent course. At the recommended dosage, Neoplatin should not be given more frequently than once every three to four weeks. (See Adverse Reactions.)

Since ototoxicity of Neoplatin is cumulative, audiometric testing should be performed prior to initiating therapy and prior to each subsequent course of the drug. (See Adverse Reactions.)

Peripheral blood counts should be monitored weekly. Liver function should be monitored periodically. Neurological examination should also be performed regularly. (See Adverse Reactions.)

Adverse reactions: Nephrotoxicity: Renal toxicity has been noted in about one third of patients given a single dose of Neoplatin when prior hydration has not been employed. It is first noted during the second week after dose and is manifested by elevations in BUN and serum creatinine, serum uric acid and/or a decrease in creatinine clearance.

Renal toxicity becomes more prolonged and severe

with repeated courses of the drug. Renal function must return to normal before another dose of Neoplatin can be given.

Renal function impairment has been associated with renal tubular damage. The administration of Neoplatin using a six to eight hour infusion with intravenous hydration and mannitol has been used to reduce nephrotoxicity. However, renal toxicity still can occur after utilisation of these procedures.

Neurotoxicity: Neurotoxicity, usually characterised by peripheral neuropathies, has occurred in some patients. Loss of taste and seizures have also been reported. Neuropathies resulting from Neoplatin treatment may occur after prolonged therapy (four to seven months); however, neurological symptoms have been reported to occur after a single dose.

Neoplatin therapy should be discontinued when the symptoms are first observed. Preliminary evidence suggests peripheral neuropathy may be irreversible in some patients.

Ototoxicity: Ototoxicity has been observed in patients treated with a single dose of Neoplatin, 50 mg/m², and is manifested by tinnitus and/or hearing loss in the high frequency range (4,000 to 8,000 Hz).

Decreased ability to hear normal conversational tones may occur occasionally. Ototoxic effects may be more severe in children receiving Neoplatin. Hearing loss can be unilateral or bilateral and tends to become more frequent and severe with repeated doses. It is unclear whether Neoplatin-induced ototoxicity is reversible. Careful monitoring by audiometry should be performed prior to initiation of therapy and prior to subsequent doses of Neoplatin.

Haematological: Myelosuppression may occur in patients treated with Neoplatin. The nadirs in circulating platelets and leucocytes occur between days 18 to 23 (range 7.5 to 45) with most patients recovering by day 39 (range 13 to 62). Leucopenia and thrombocytopenia are more pronounced at higher doses. Anaemia (decrease in haemoglobin level by 2 g/100 ml blood) occurs at approximately the same frequency and with the same timing as leucopenia and thrombocytopenia.

Gastro-intestinal: Marked nausea and vomiting occur in almost all patients treated with Neoplatin and are occasionally so severe that the drug must be discontinued. Nausea and vomiting usually begin within one to four hours after treatment and last up to 24 hours. Various degrees of nausea and anorexia may persist for up to one week after treatment.

Other toxicities: Hyperuricaemia: Hyperuricaemia has been reported to occur at approximately the same frequency as the increases in BUN and serum creatinine. It is more pronounced after doses greater than 50 mg/m², and peak levels of uric acid generally occur between three to five days after the dose. Allopurinol therapy for hyperuricaemia effectively reduces uric acid levels.

Anaphylactic-like reactions: Anaphylactic-like reactions, possibly secondary to Neoplatin therapy, have been occasionally reported in patients previously exposed to Neoplatin. The reactions consist of facial oedema, wheezing, tachycardia and hypotension within a few minutes of drug administration. All reactions may be controlled by intravenous adrenaline, corticosteroids or antihistamines. Patients receiving Neoplatin should be observed carefully for possible anaphylactic-like reactions and supportive equipment and medication should be available to treat such a complication.

Other toxicities reported to occur infrequently are cardiac abnormalities, anorexia and elevated SGOT.

Pharmaceutical precautions Neoplatin injection should be stored at room temperature.

Expiry date: 36 months from date of manufacture.

Preparation of intravenous solution: Reconstitute the 10 mg vial contents with 10 ml, and the 50 mg vial contents with 50 ml of Sterile Water for Injection PhEur. The resulting drug solution is then administered in 2 litres of a suitable diluent, such as 0.9% saline, or a dextrose-saline solution. It is recommended that administration should be over a six to eight hour period. Diuresis may be aided by the addition to the infusion solution of 37.5 g mannitol.

The reconstituted solution should be protected from light, kept at room temperature and is stable for 20 hours. Refrigeration will result in precipitation.

Legal category POM.

Package quantities Neoplatin injection is packed in cartons of 10 vials, each vial containing 10 mg or 50 mg lyophilised cisplatin.

Further information Cisplatin has biochemical properties similar to that of bifunctional alkylating agents producing inter-strand and intra-strand crosslinks in DNA. It is apparently cell-cycle non-specific. Following a single i.v. dose, cisplatin concentrates in liver, kidneys, and large and small intestines in animals and humans. Cisplatin apparently has poor penetration into the CNS.

Plasma levels of radioactivity decay in a biphasic manner after an i.v. bolus dose of radioactive cisplatin to patients. The initial plasma half-life is 25 to 49 minutes, and the post-distribution plasma half-life is 58 to 73 hours. During the post-distribution phase, greater than 90% of the radioactivity in the blood is protein-bound. Cisplatin is excreted primarily in the urine. However, urinary excretion is incomplete with only 27 to 43% of the radioactivity being excreted within the first five days post-dose in human beings. There are insufficient data to determine whether biliary or intestinal excretion occurs.

Product licence number 0125/0109.

PENTREXYL* CAPSULES

Presentation Pentrexyl Capsules (Ampicillin Capsules BP): Grey and scarlet capsules containing 250 mg or 500 mg (overprinted BRISTOL/BRISTOL) ampicillin as ampicillin trihydrate BP.

Uses Pentrexyl is a broad-spectrum antibiotic indicated for the treatment of infections due to susceptible Gram-positive organisms including streptococci, pneumococci, penicillin G sensitive staphylococci and enterococci and susceptible strains of Gram-negative bacteria including *H. influenzae*, *E. coli*, *Proteus mirabilis*, *N. gonorrhoeae*, *N. meningitidis*, *Shigellae*, *S. typhi* and other *Salmonellae*.

Typical indications include: ear, nose and throat infections, bronchitis, pneumonia, urinary tract infections, gonorrhoea, gynaecological infections, septicaemia, peritonitis, endocarditis, meningitis, enteric fever, gastro-intestinal infections.

Dosage and administration To ensure maximum

absorption Pentrexyl should be administered orally at least one hour before or after meals.

Usual adult dose: Ear, nose and throat infections: 250 mg four times a day.

Bronchitis: routine therapy – 250 mg four times a day; high dosage therapy – 1 g four times a day.

Pneumonia: 500 mg four times a day.

Urinary tract infections: 500 mg three times a day.

Gonorrhoea: 3.5 g orally with 1 g probenecid as a single dose. Repeated doses are recommended for the treatment of females.

Gastro-intestinal infections: 500–750 mg three to four times daily.

Enteric: acute – 1–2 g four times a day for two weeks; carriers – 1–2 g four times a day for four to twelve weeks.

Usual children's dose (under 10 years): Half adult dose.

All recommended dosages are given as a guide only and such dosages may be increased in severe infections. A minimum of 10 days' treatment is recommended for any infection caused by Group A Beta-Haemolytic Streptococci to help prevent the occurrence of acute rheumatic fever or acute glomerulonephritis.

Contra-indications, warnings, etc

Contra-indication: A history of hypersensitivity to any of the penicillins.

Side-effects: As with other penicillins side-effects are rare and usually of a mild, transient nature. It may be expected that untoward reactions will be essentially limited to the sensitivity phenomena. Side-effects are more likely to occur in individuals who have previously demonstrated hypersensitivity to penicillins and in those with a history of allergy, asthma, hay fever or urticaria. Rashes of two types have been recorded – an urticarial rash, which is usually indicative of true penicillin hypersensitivity, and an erythematous rash which is generally specific to ampicillin. The incidence of the latter is particularly high in patients with infectious mononucleosis. In such cases therapy should be discontinued.

Pharmaceutical precautions Pentrexyl should be stored in a cool, dry place. Expiry Date – 36 months from date of manufacture.

Legal category POM.

Package quantities *Pentrexyl 250 mg:* Containers of 500 capsules.

Pentrexyl 500 mg: Containers of 100 capsules.

Further information Nil.

Product licence numbers

Pentrexyl Capsules 250 mg 0125/0080

Pentrexyl Capsules 500 mg 0125/0081

QUESTRAN*

Presentation Questran sachets containing 9 g of orange-flavoured powder. Each sachet supplies 4 g of anhydrous cholestyramine (a basic anion-exchange resin).

Uses Questran is used for:

1. Reduction of plasma cholesterol in hypercholesterolaemia, particularly in those patients who have been diagnosed as Fredrickson's Type II (high plasma cholesterol with normal or slightly elevated triglycerides).

2. Relief of diarrhoea associated with ileal resection

Crohn's disease, vagotomy and diabetic vagal neuropathy.

3. Relief of pruritus associated with partial biliary obstruction.

4. Management of radiation-induced diarrhoea.

Dosage and administration *Adults:* As a precautionary measure, where concurrent drug therapy exists then such drugs should be administered 30 minutes to 1 hour before Questran.

1. To reduce cholesterol: After initial introduction, 3 to 6 Questran sachets per day, administered either as a single daily dose or in divided doses up to four times daily according to dosage requirement and patient acceptability. Dosage may be modified according to response and can be increased to 9 sachets per day if necessary.

2. To relieve diarrhoea: as for reduction of cholesterol, but it may be possible to reduce this dosage.

3. To relieve pruritus: 1 or 2 sachets daily are usually sufficient. Questran may be administered mixed with water, skimmed milk, fruit juice, soups, pulpy fruit, etc.

Children 6–12 years: The initial dose is determined by the following formula:

$$\text{child's weight in lb} \times \text{adult dose}$$

$$150$$

Subsequent dosage adjustment may be necessary.

Infants and children under 6 years: The dose has not been established.

Contra-indications, warnings, etc Questran is contra-indicated in patients with complete biliary obstruction, since Questran cannot be effective where bile is not secreted into the intestine.

Because it sequesters bile acids, Questran may interfere with normal fat absorption and prevent absorption of fat-soluble vitamins such as A, D and K. If Questran is to be administered in high dosage for a prolonged period, fat-soluble vitamins should be given daily in a water-miscible form, or, if preferred, administered parenterally.

Gastro-intestinal side-effects are those most frequently reported. The principal complaint is constipation, which may be controlled with the usual remedies, and frequently disappears on continued usage of Questran.

The use of Questran in pregnancy or lactation or by women of childbearing age requires that the potential benefits of drug therapy be weighed against the possible hazards to the mother and child. The safe use of Questran by pregnant women has not been established.

Pharmaceutical precautions Questran should not be taken in its dry form. The powder should be prepared immediately prior to administration.

There are no special directions for storage.

Expiry Date – 48 months from date of manufacture.

Legal category POM.

Package quantities Questran is available in cartons containing 40 sachets.

Further information The correlation between high blood cholesterol levels and ischaemic heart conditions has prompted the dietary control of patients who have shown signs or symptoms of coronary artery disease. With Questran it is possible to reduce cholesterol levels without recourse to excessively stringent dietary measures or systemically absorbed drugs.

Questran (cholestyramine) is a basic anion-exchange resin. It is not absorbed in the gut and its affinity for bile acids in the intestinal tract prevents their reabsorption. To compensate for the faecal loss of bile acids, their major precursor, cholesterol, is oxidised at an increased rate in the liver and plasma cholesterol levels are thus lowered.

Product licence number 0125/5009.

SOTACOR*

Presentation *Sotacor tablets:* Sotacor 80 mg tablets – pink, circular, tablets, engraved 'SOTACOR 80' on one face, each tablet containing 80 mg sotalol hydrochloride.

Sotacor 160 mg tablets – blue, circular, tablets, engraved 'SOTACOR 160' on one face, each containing 160 mg sotalol hydrochloride.

Sotacor injection: Ampoules containing sotalol hydrochloride 10 mg in each 5 ml of solution.

Uses Sotacor, the hydrochloride of 4-(2-isopropylamino-1-hydroxyethyl)-methanesulphonanilide, is a synthetic beta-adrenergic receptor blocking agent. Sotacor exerts a significant antihypertensive effect and additionally protects the heart from undesirable sympathetic drive. It is devoid of intrinsic sympathomimetic and local anaesthetic activity.

1. *Hypertension:* Sotacor produces smooth and gradual reduction of blood pressure on a long-term basis.

2. *Angina pectoris:* Sotacor reduces the frequency and severity of anginal attacks and increases exercise tolerance.

3. *Thyrotoxicosis:* Sotacor relieves the effect of adrenergic over-activity.

4. *Cardiac arrhythmias:* Sotacor tablets may be used prophylactically and as maintenance therapy in the management of cardiac arrhythmias. Sotacor Injection is used in the management of acute cardiac arrhythmias, especially following myocardial infarction, to restore normal rate and rhythm.

Dosage and administration When administering beta-blocking drugs to previously untreated patients it is desirable to start with a low dose and gradually increase the dose until optimum response has occurred. It is usually undesirable to reduce the heart rate below 55 beats per minute.

Sotacor Tablets: Sotacor may be administered daily in either single or divided doses.

Children: Sotacor is not intended for administration to children.

Adults: 1. *Hypertension:* Initial daily dose should be one 160 mg tablet. The majority of mild to moderate hypertensives will respond to one tablet daily and be adequately controlled at this level.

2. *Angina pectoris:* Initial daily dose should be one 160 mg tablet. The majority of anginal patients will be controlled at this dosage level.

N.B. A gradual transfer of therapy over a two-week period is recommended in patients receiving other anti-anginal therapy.

3. *Thyrotoxicosis:* Initial daily dose should be one 160 mg tablet.

4. *Arrhythmia:* In the management of cardiac arrhythmia.

mias, as prophylaxis or maintenance therapy, Sotacor dosage will normally be between 160 mg and 240 mg daily.

N.B. In all these indications dosage may be increased by increments of up to 160 mg per day – the rapidity with which this dosage increase takes place depends upon the patient's tolerance, particularly as measured by the degree of induced bradycardia and the clinical response.

Sotacor Injection should be administered slowly in doses of 20–60 mg intravenously over two to three minutes. Larger doses, up to 100 mg should be injected over three minutes or longer. Continuous ECG monitoring is recommended. Should repeated administrations be necessary, a 10-minute interval between injections is advised, remembering that additive effect and prolongation of effect may ensue.

Contra-indications, warnings, etc Sotacor should not be used where there is evidence of heart block; metabolic acidosis; history of bronchospasm; diabetic ketoacidosis. Beta-blockade may precipitate heart failure in subjects with poor cardiac reserve or may aggravate existing heart failure. Patients whose heart failure is well controlled with digitalis and diuretics may be given Sotacor.

Treated diabetes: Sotacor, like other beta-blocking drugs, may reduce or mask pre-hypoglycaemic warning signs.

Anaesthesia: It is not necessary to discontinue Sotacor prior to most forms of elective surgery, although there is some doubt as to whether beta-receptor blockers should be continued up to the time of surgery involving cardiopulmonary bypass. However, as with other beta-blockers, sudden withdrawal of Sotacor Tablets or Injection might expose the patient to severe angina, arrhythmias, and even myocardial infarction.

If the drug is to be discontinued prior to surgery, especially in patients with ischaemic heart disease, then the drug should be withdrawn over a period of one week. It is usual to discontinue Sotacor Injection 24 to 48 hours prior to elective surgery.

In the presence of Sotacor, anaesthesia may proceed provided that vagal dominance is counteracted by an intravenous injection of atropine sulphate (0.5–2 mg) immediately prior to induction of anaesthesia. Some anaesthetic agents such as ether, cyclopropane, trichloroethylene, methoxyflurane and enflurane appear to cause impairment of myocardial contractility in the presence of beta-receptor blockade. Caution is advised in the use of these agents in patients receiving Sotacor. No evidence of serious interaction has been found between nitrous oxide, halothane or isoflurane and beta-receptor blockers. Raised pCO_2 levels should be avoided in patients receiving Sotacor.

Pregnancy: Notice should be taken of current views on the undesirability of administering drugs during pregnancy. Animal studies with sotalol hydrochloride have shown no evidence of teratogenicity or other harmful effects on the fetus.

Side-effects: There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual.

Sotacor tablets: At the recommended dosage side effects are uncommon. However, minor side effects such as bradycardia, nausea, insomnia, lassitude and diarrhoea have been reported. These are usually transient and can be avoided by gradual introduction of treatment and usually remit on reduction of dosage.

Sotacor Injection is usually well tolerated. Side effects due to beta-blockade, manifested as bradycardia and hypotension, should be treated, if necessary, as for overdosage.

Overdosage: In the rare event of profound cardiovascular effects such as excessive bradycardia or hypotension, atropine sulphate, 0.5–2 mg intravenously, should be administered. It may also be necessary to administer isoprenaline 5 mcg per minute, up to 25 mcg, by slow intravenous injection in order to reverse beta-receptor blockade.

Pharmaceutical precautions Sotacor Tablets should be protected from light.

Expiry Date:

Sotacor 80 mg	36 months	from	date of
	manufacture.		
Sotacor 160 mg	36 months	from	date of
	manufacture.		
Sotacor Injection	36 months	from	date of
	manufacture.		

Legal category POM.

Package quantities *Sotacor 80 mg tablets:* Units of 100 and 300.

Sotacor 160 mg tablets: Units of 28 – blister strips of 14 tablets with 2 strips to a carton.

Sotacor Injection is supplied as 10 mg sotalol hydrochloride in 5 ml ampoules, with 5 ampoules per box.

Further information The maximum dose of Sotacor is usually 320 mg daily. Where improved control of hypertension is required the addition of a diuretic will often give a more satisfactory response.

SOTAZIDE*

Presentation *Sotazide tablets:* Pale blue, capsule-shaped, concave, upper bisected tablets containing 160 mg sotalol hydrochloride and 25 mg hydrochlorothiazide.

Uses In the management of mild or moderate hypertension. The combination product may be suitable for use when satisfactory control of arterial blood pressure cannot be obtained with either a diuretic or a beta-adrenoreceptor blocking drug used alone.

Dosage and administration *Initial dose:* One Sotazide tablet daily increasing to two if necessary.

The individual optimal dosage and the rapidity with which dosage increase occurs should be determined from blood pressure and pulse rate readings and by the degree of induced bradycardia.

Following a reduction in blood pressure the dosage should not be increased until the new blood pressure is stable.

A slight reduction in dosage will alleviate symptoms of

weakness and dizziness if blood pressure continues to fall after a month or two on the maintenance dose.

Contra-indications, warnings, etc

Contra-indications: Sotazide should not be used where there is evidence of heart block; history of bronchospasm; diabetic keto-acidosis; impending or uncontrolled cardiac failure; anaesthesia that produces myocardial depression; hypersensitivity to sotalol, hydrochlorothiazide or sulphonamide derivatives.

Since thiazides appear in breast milk, patients should stop nursing if the use of Sotazide is essential.

Warnings: *Pregnancy:* In animal studies Sotazide has been shown to have no adverse teratogenic effects in doses up to 25 times the recommended human dose. However, its safe use in human pregnancy has not been fully established.

Treated diabetes: Hypoglycaemic therapy may have to be altered in diabetics; Sotazide may potentiate the insulin hypoglycaemic effects and mask the symptoms of hypoglycaemia.

Hepatic/renal disease: Sotazide should be used with caution in patients with impaired hepatic function, liver disease or severe renal disease, since they are particularly sensitive to alterations of fluid and electrolyte balance. Thiazides may precipitate azotaemia. Cumulative effects of the hydrochlorothiazide may develop in patients with impaired renal function.

Anaesthesia: It is not necessary to discontinue Sotazide prior to most forms of elective surgery, although there is some doubt as to whether beta-receptor blockers should be continued up to the time of surgery involving cardiopulmonary bypass. However, sudden withdrawal of Sotazide might expose the patient to severe angina, arrhythmias, and even myocardial infarction.

If the drug is to be discontinued prior to surgery, especially in patients with ischaemic heart disease, then the drug should be withdrawn over a period of one week.

In the presence of Sotazide, anaesthesia may proceed provided that vagal dominance is counteracted by an intravenous injection of atropine sulphate (0.5–2 mg) immediately prior to induction of anaesthesia. Some anaesthetic agents such as ether, cyclopropane, trichloroethylene, methoxyflurane and enflurane appear to cause impairment of myocardial contractility in the presence of beta-receptor blockade. Caution is advised in the use of these agents in patients receiving Sotazide. No evidence of serious interaction has been found between nitrous oxide, halothane, or isoflurane and beta-receptor blockers. Raised pCO₂ levels should be avoided in patients receiving Sotazide.

Precautions: In view of the minimal myocardial depressant effect of sotalol and the lack of myocardial effect of hydrochlorothiazide, Sotazide has only a remote potential for precipitation or exacerbation of cardiac failure. Nevertheless, Sotazide should not be given to patients with cardiac decompensation unless incipient or established heart failure is controlled. At the first sign of impending cardiac failure or the progression of failure, Sotazide dosage should be reduced or discontinued.

The dosage of Sotazide should be decreased or therapy discontinued if the pulse rate falls below 50 beats/minute. Following a reduction in blood pressure, the dosage of Sotazide should not be increased before a stable level of blood pressure is attained.

Sudden withdrawal of treatment with beta-blockers in hypertensive patients with angina pectoris has induced severe and continuous angina in some cases. Although

this effect has not been observed with Sotazide, should such a reaction occur, Sotazide treatment should be reinstituted and then withdrawn gradually by reducing the dosage over a period of weeks.

All patients receiving hydrochlorothiazide (as in Sotazide) therapy should be checked periodically for clinical signs of fluid or electrolyte imbalance: hyponatraemia, hypochlorhaemic alkalosis and hypokalaemia. Hypokalaemia can sensitise or exaggerate the response of the heart to the toxic effects of cardiac glycosides. With the lower dose of hydrochlorothiazide present in Sotazide, the possibility of any imbalance becomes less likely.

With the use of hydrochlorothiazide (as in Sotazide), serum protein-bound iodine may decrease without producing symptoms of thyroid disturbance.

Side-effects: The overall incidence of side-effects with Sotazide is low. The few reported adverse reactions were largely the pharmacological effects seen with the use of beta-blocking agents and diuretics. These reactions are mild, or moderate in intensity, most often transitory, and usually do not require interruption or withdrawal of therapy.

Sotalol, when used alone, is generally well tolerated. Dyspnoea, tiredness, dizziness, light-headedness, headache, fever and excessive bradycardia have been reported. Most of these side-effects are transient or disappear when the dosage is reduced, e.g. with the use of Sotazide.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual.

Hyperuricaemia has been observed with thiazides but clinical gout is rare. Other side-effects for thiazides are documented but uncommon. Photosensitivity, anaphylactic reactions and depression of the formed elements of the blood have been reported.

The relevance of these observations to Sotazide therapy has not yet been determined.

Overdosage: If excessive bradycardia (and/or hypotension) occurs, atropine 0.5–2.0 mg should be given intravenously, immediately followed, if necessary, by a beta-receptor stimulating agent, such as isoprenaline, intravenously, 5 mcg/minute up to 25 mcg initially.

Pharmaceutical precautions *Expiry data:* 24 months from date of manufacture.

Legal category POM.

Package quantities Units of 28 – blister strips of 14 tablets with 2 strips per carton.

Further information Sotazide is an effective anti-hypertensive which combines sotalol hydrochloride, a beta-adrenergic blocking agent, and hydrochlorothiazide, a diuretic/antihypertensive. The concomitant use of these agents frequently produces a more pronounced anti-hypertensive effect than if either is used alone. By using lower doses than would be required if each agent were used alone, side-effects, especially the hypokalaemia associated with diuretics, are minimised. In hypertensive patients, where sodium and water retention is frequently a problem, the diuretic component will help control fluid imbalance.

Product licence number 0125/0113.

STADOL* ▼

Presentation Vials containing 2 mg butorphanol tartrate in 1 ml solution. Vials containing 4 mg butorphanol tartrate in 2 ml solution.

Uses Stadol is a strong non-narcotic synthetic analgesic of the phenanthrene series.

Stadol is indicated for:

- (a) pre-anaesthetic medication;
- (b) intra-operative use;
- (c) relief of moderate to severe pain.

Dosage and administration *Adults: Intravenous:* The usual recommended single dose is 1 mg repeated every three to four hours as necessary. The effective dose range is 0.5–2 mg.

Intramuscular: The usual recommended single dose is 2 mg repeated every three to four hours as necessary. The effective dose range is 1–4 mg.

Children: Stadol is not at present recommended for administration to children.

Contra-indications, warnings, etc

Prior narcotic administration: Because of its antagonist properties, Stadol should not be given to patients physically dependent on narcotics. Caution should be exercised in the administration of Stadol to patients who have recently received narcotic medication.

Head injury: Stadol may produce miosis and this could obscure the clinical progress of patients with head injury.

Cardiovascular disease: Stadol increases cardiac work, especially in the pulmonary circuit, and is not at present recommended for use in patients with acute myocardial infarction.

Respiratory disease: Some respiratory depression may be produced by Stadol and it should thus be used with caution in patients with severely limited respiratory reserve or obstructive airways disease or in patients with pre-existing respiratory depression caused by other disease states or drug administration. Naloxone is a specific antagonist for Stadol-induced respiratory depression.

Renal and hepatic dysfunction: Though laboratory investigations have not indicated that Stadol causes or increases renal or hepatic impairment, extensive disease may predispose to greater activity and side-effects from usual clinical doses possibly as a result of decreased metabolism and excretion.

Biliary surgery: Clinical studies with Stadol have not been undertaken in patients about to undergo biliary tract surgery.

Pregnancy and labour: Stadol is not presently recommended for use in pregnancy or in nursing mothers. However, safety of Stadol administration in labour has been established.

Operating machinery, etc: As Stadol may produce sedation and dizziness, patients should be warned not to drive or operate machinery.

Side-effects: Sedation (ranging from mild drowsiness to actual sleep) is the most common side-effect. Vertigo, dizziness, and nausea may occur. Alteration of mood and vivid dreams are infrequent. Other side-effects are rare. All of these reactions occur more frequently in patients with recent narcotic experience.

Dependence liability: Human and animal studies conducted show that Stadol has a low physical dependence

liability. Nevertheless, caution should be used in prescribing Stadol to patients who have a history of drug abuse.

Pharmaceutical precautions *Expiry Date:* 24 months from date of manufacture.

Legal category POM.

Package quantities Stadol injections are available in packs of 25 vials per carton.

Further information *Analgesic activity:* Stadol is a strong analgesic. Analgesia occurs within 30 minutes of intramuscular injection and within two minutes of intravenous injection. Peak analgesic activity occurs at approximately 60 minutes after intramuscular and 30 minutes after intravenous administration.

Respiratory effects: At an analgesic dose of 2 mg Stadol depresses respiration to a degree equal to that seen with 10 mg morphine. There is no appreciable increase in the magnitude of respiratory depression with a 4 mg dose but the duration of depression is dose related. Stadol-induced respiratory depression is completely reversible by naloxone (which is a specific antagonist).

Injection 2 mg per 1 ml 0125/0100

Injection 4 mg per 2 ml 0125/0100

TETREX* CAPSULES

Presentation Capsules having an orange body and yellow cap, printed 'BRISTOL/BRISTOL' in green. Each capsule contains tetracycline phosphate compound equivalent to tetracycline activity 250 mg.

Uses The absorption of tetracycline may be inhibited in the presence of calcium ions in the intestinal contents. The phosphate component of Tetrex combines with calcium and leaves more free tetracycline available for absorption.

Tetrex is indicated in the treatment of the following infections when due to sensitive organisms:

- Infections of the respiratory tract.
- Infections of the gastro-intestinal tract.
- Infections of the genito-urinary tract.
- Infections of the skin and soft tissues.

Dosage and administration *Adults:* Usual dose 1 g per day in 4 divided doses of 250 mg each or 2 divided doses of 500 mg each.

Higher doses may be required to control acute episodes.

Acute gonococcal urethritis – 500 mg three times daily for one to two days. Female patients require more prolonged therapy.

Children: Usual dose 25 mg/kg/day in 4 divided doses. Children weighing more than 40 kg should be given the recommended adult dose.

Therapy for most infections should be continued for 24–48 hours after the patient has become asymptomatic or afebrile.

Contra-indications, warnings, etc This drug is contra-indicated in individuals who have shown serious hypersensitivity to tetracycline, unless the need for this therapy necessitates its use with proper safeguards.

If renal impairment exists, even usual oral doses of the drug may lead to excess systemic accumulation of tetracycline and possible liver toxicity. Under such

conditions, lower than usual doses are indicated, and if therapy is prolonged, tetracycline serum-level determinations may be advisable.

Tetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans. However, use of tetracycline during tooth development (last trimester of pregnancy, neonatal period, infancy and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term therapy, but it has also been observed following short treatment courses.

Enamel hypoplasia has been observed in a few children. If superinfection with non-susceptible organisms occurs proper measures should be taken.

Pharmaceutical precautions Expiry date – 36 months from date of manufacture.

There are no special directions for storage.

Legal category POM.

Package quantities Containers of 100 capsules.

Further information Tetracycline phosphate compound is absorbed rapidly from the gastro-intestinal tract providing reliable high tetracycline levels in the blood. It is serum bound to a much lesser degree than most other tetracyclines and therefore allows greater concentrations of active antibiotic to reach the site of infection.

Product licence number 0125/0066.

VEPESID* CAPSULES ▼

VEPESID* INJECTION ▼

Presentation Vepesid Injection-ampoules containing 100 mg etoposide in 5 ml.

Vepesid Capsules-soft gelatin capsules containing 100 mg etoposide.

Uses Vepesid is an anti-neoplastic drug for intravenous or oral use, which can be used alone or in combination with other oncologic drugs.

Present data indicate that Vepesid is applicable in the therapy of: small cell lung cancer, resistant non-seminomatous testicular carcinoma.

Dosage and administration The recommended course of Vepesid Injection is 60–120 mg/m², i.v., daily for five consecutive days. As Vepesid produces myelosuppression, courses may not be repeated more frequently than at 21 day intervals. In any case, repeat courses of Vepesid should not be given until the blood picture has been checked for evidence of myelosuppression and found to be satisfactory.

Immediately before administration, the required dose of Vepesid Injection must be diluted with 0.9% saline solution for injection to give a solution concentration of not more than 0.25 mg/ml of etoposide; it should then be given by intravenous infusion over a period of not less than 30 minutes.

Care should be taken to avoid extravasation.

If oral dosing is preferred, twice the relevant i.v. dose should be given daily, for five consecutive days. As Vepesid produces myelosuppression, courses may not be repeated more frequently than at 21 day intervals. In any case, repeat courses of Vepesid should not be given until the blood picture has been checked for evidence of myelosuppression and found to be satisfactory.

Contra-indications, warnings, etc Vepesid is contra-indicated in patients with severe hepatic dysfunction

or in those patients who have demonstrated hypersensitivity to the drug.

Vepesid must not be given by intra-cavity injection.

Warnings: Vepesid should not normally be administered to patients who are pregnant or to mothers who are breast feeding. Safe use in pregnancy has not been established.

Vepesid is teratogenic in rats at dose levels equivalent to those employed clinically.

The influence of Vepesid on human reproduction has not been determined.

In-vitro tests indicate that Vepesid is mutagenic.

Precautions: Vepesid should be administered by individuals experienced in the use of antineoplastic therapy.

When Vepesid is administered intravenously care should be taken to avoid extravasation.

If radiotherapy and/or chemotherapy has been given prior to starting Vepesid treatment, an adequate interval should be allowed to enable the bone marrow to recover. If the leucocyte count falls below 2,000/mm³, treatment should be suspended until the circulating blood elements have returned to acceptable levels (platelets above 100,000/mm³, leucocytes above 4,000/mm³), this is usually within 10 days.

Peripheral blood counts and liver function should be monitored. (See Adverse Reactions.)

Bacterial infections should be brought under control before treatment with Vepesid commences.

Adverse reactions: Haematological: The dose limiting toxicity of Vepesid is myelosuppression, predominantly leucopenia and thrombocytopenia. Anaemia occurs infrequently.

The leucocyte count nadir occurs approximately 21 days after treatment.

Alopecia: Alopecia occurs in approximately 50% of patients and is reversible on cessation of therapy.

Gastrointestinal: Nausea and vomiting are the major gastrointestinal toxicities and occur in approximately 30% of patients. Anti-emetics are useful in controlling these side effects. Abdominal pain, diarrhoea and anorexia occur infrequently.

Other Toxicities: Hypotension may occur following an excessively rapid infusion and may be reversed by slowing the infusion rate.

Anaphylactic-like reactions have been reported rarely following administration of Vepesid. Reactions respond to cessation of therapy and administration of an antihistamine.

No specific toxic effects have been observed with respect to the cardiovascular system, nervous system, the liver or kidney. However, Vepesid has been shown to reach high concentrations in the latter two organs, thus presenting a potential for accumulation in cases of functional impairment.

Pharmaceutical precautions Vepesid capsules and injection should be stored at room temperature. The injection should be protected from light.

Preparation of intravenous solution: Immediately before administration the required dose of Vepesid Injection must be diluted with 0.9% saline solution for injection to give a solution concentration of not more than 0.25 mg/ml of etoposide; it should then be given by intravenous infusion over a period of not less than 30 minutes. The infusion solution should be kept at room temperature and should be used within six hours of preparation. Solutions of concentration greater than

0.25 mg/ml may show signs of precipitation, and are therefore not recommended. Any solutions showing signs of precipitation should be discarded.

The intravenous solution is suitable for infusion in glass or PVC containers.

Vepesid should not be physically mixed with any other drug.

Expiry date: Vepesid injection: 5 years from date of manufacture. Vepesid capsules: 2 years from date of manufacture.

Legal category POM.

Package quantities Vepesid injection is packed in cartons of 10 ampoules, each ampoule containing 100 mg etoposide in 5 ml of solution.

Vepesid capsules are packed in bottles of 10 capsules, each capsule containing 100 mg etoposide.

Further information Etoposide is a semisynthetic derivative of podophyllotoxin.

Experimental data indicate that etoposide arrests the cell cycle in the G₂ phase. Etoposide differs from the

vinca alkaloids in that it does not cause an accumulation of cells in metaphase, but prevents cells from entering mitosis or destroys cells in the G₂ phase. The incorporation of thymidine into DNA is inhibited in-vitro by etoposide. Etoposide does not interfere with microtubule assembly. Etoposide is approximately 94% protein-bound in human serum. Plasma decay kinetics follow a bi-exponential curve and correspond to a two compartmental model. The mean volume of distribution is approximately 32% of body weight. Etoposide demonstrates relatively poor penetration into the cerebrospinal fluid. Urinary excretion is approximately 45% of an administered dose, 29% being excreted unchanged in 72 hours.

An information sheet on the storage, preparation and handling of the product is available

AMFIPEN* CAPSULES
AMFIPEN* SYRUP
AMFIPEN* SYRUP FORTE
AMFIPEN* INJECTION

Presentation Amfipen Capsules (Ampicillin Capsules BP) are presented as grey and red capsules each containing 250 mg or 500 mg Ampicillin BP, imprinted 'Amfipen 250' or 'Amfipen 500'.

Amfipen Syrup (Ampicillin Mixture BPC) and Amfipen Syrup Forte (Strong Ampicillin Mixture BPC) are presented as bottles containing dry powder for the preparation of 100 ml of a pink-coloured suspension. On reconstitution each 5 ml dose contains 125 mg or 250 mg respectively Ampicillin BP.

Amfipen Injections (Ampicillin sodium for injection BP) are presented as vials containing 250 mg or 500 mg ampicillin as Ampicillin Sodium BP.

Uses Amfipen is a broad-spectrum penicillin for the treatment of a wide range of infections caused by ampicillin-sensitive organisms.

Dosage and administration *Usual adult oral dosage:* Ear, nose and throat infections: 250 mg four times a day.

Bronchitis: usually 250 mg four times a day in routine therapy; 1 g four times a day in high-dosage regimes.

Pneumonia: 500 mg four times a day.

Gastro-intestinal infection: 500–750 mg three or four times daily.

Urinary tract infections: 500 mg four times daily.

Enteric fevers: in acute cases 1–2 g four times a day for 14 days; carriers should be treated with this dosage for 4–12 weeks.

In the treatment of gonorrhoea 2 g should be given with 1 g probenecid as a single dose. In the treatment of females repeated doses are recommended.

Usual children's oral dosage: Half of the adult dosage.

The doses above are recommended dosages, only as a guide. In severe infections the dosages may be increased.

Amfipen should be given a half to one hour before meals.

Usual adult parenteral dosage: Septicaemia, endocarditis, osteomyelitis: 500 mg four to six times a day for one to six weeks by intramuscular or intravenous injection.

Meningitis: 2 g six-hourly for two days by intravenous injection, followed by 500 mg to 1 g six-hourly by intramuscular injection.

Usual children's parenteral dosage: Meningitis: 100 g per kg daily in divided doses by intravenous injections for two days, followed by 100 mg per kg daily.

The dosages above are recommended dosages only as a guide. In severe infections the dosages may be increased.

Administration: Amfipen may be administered orally as capsules or syrup or syrup forte. Parenteral dosage by means of Amfipen Injection should be administered as follows: For intramuscular injection dissolve 250 mg or

500 mg in 1.5 ml water for injections BP. For intravenous injection dissolve 500 mg in 10 ml water for injections BP and administer by injection over three to four minutes. For intraperitoneal injection and intrapleural injection dissolve 500–1,000 mg in 5–10 ml water for injections BP. For intra-articular injection 500 mg dissolved in up to 5 ml water for injections BP or 0.5% procaine hydrochloride.

Contra-indications, warnings, etc

Contra-indicated in patients with penicillin hypersensitivity and glandular fever.

Side-effects: Skin reactions may occur rarely, and be due to either penicillin hypersensitivity (urticarial rash) or specific ampicillin sensitivity (erythematous rash); treatment should be discontinued if a rash occurs. Occasionally, diarrhoea may occur. As with all ampicillins, Amfipen may reduce the efficacy of oral contraceptives, and patients should be warned accordingly.

Pharmaceutical precautions Amfipen preparations should be stored in a cool dry place. On reconstitution, Amfipen Syrup and Amfipen Syrup Forte should be used within seven days if stored in a cool place.

In order to obtain a homogeneous suspension it is recommended that the bottle be well shaken before reconstitution of the syrup.

Legal category POM.

Package quantities *Amfipen Capsules 250 mg:* Bottles of 250, and packs of 2,500.

Amfipen capsules 500 mg: Bottles of 250, and packs of 1,500.

Amfipen Syrup and Syrup Forte: Bottles for the preparation of 100 ml.

Amfipen Injections 250 mg and 500 mg: Boxes of 10 vials.

Further information Nil.

ANTRADERM* MILD
ANTRADERM* ▼
ANTRADERM* FORTE ▼

Presentation *Antraderm Mild:* a pale yellow wax containing dithranol BP 0.5%. *Antraderm:* a pale yellow wax containing dithranol BP 1.0%. *Antraderm Forte:* a pale yellow wax containing dithranol BP 2.0%. Each presentation is packed as 8 g sticks in a plastic twist-up container.

Uses For the topical treatment of subacute and chronic psoriasis.

Dosage and administration Clinical experience has shown that, as with other methods of treatment, patient response is rather individualised and therefore it may be necessary to adjust treatment during the initial period. It is recommended that treatment be normally started with the 1.0% concentration. If irritation or stinging occurs and it persists the problem can often be overcome by changing to the lower 0.5% strength. If the effect of the 1.0% strength is insufficient or if tolerance develops after a period of treatment the 2.0% strength will often produce the required response.

Antraderm should be applied directly to the lesions, preferably at night before bedtime. The tip of the wax stick is softened by skin temperature enabling a thin layer of dithranol to be applied gently over the lesions. When treating very scaly lesions, the debris should be removed before applying Antraderm.

Treatment should continue until the skin is clear. Intermittent courses may be required to maintain therapeutic response.

Contra-indications, warnings, etc A small proportion of patients initially experience slight toxic reactions to dithranol. This reaction is often transient and is usually seen during the first 2-3 days of treatment. It is more likely to occur when potent topical steroids have recently been used. These effects can usually be overcome by:

- reducing the frequency of treatment for a few days e.g. applications very 2nd or 3rd night.
- using a lower concentration of Antraderm. If neither action overcomes the toxic response, it may be necessary to stop treatment.

Antraderm must not be used for psoriasis in the acute phase. Care should be taken to avoid application to surrounding areas of unaffected skin.

An excessive quantity should not be applied as this may cause unnecessary staining of clothing and bed linen. In the morning a bath will remove any surplus dithranol.

During treatment the edges of the lesions will gradually acquire a purplish-brown stain which will completely disappear after the treatment has finished.

Pharmaceutical precautions Keep in a cool place. Use within 6 months of breaking the foil outer pack.

Legal category

Antraderm Mild	P.
Antraderm	POM.
Antraderm Forte	POM.

Package quantities All strengths are supplied in 8 g sticks.

Further information Antraderm is suitable for home treatment as its advantages make it easier and more economic in use than other forms of dithranol. It is however equally suitable for use in dermatology wards and clinics as a standard dithranol treatment.

BICILLIN* INJECTION

Presentation Bicillin Injection is presented as vials of dry powder for the preparation of Fortified Procaine

Penicillin Injection BP. Each vial contains 3 mega units (3 g) procaine penicillin G and 1 mega unit (0.6 g) sodium penicillin G.

Uses Antibiotic for the treatment of infections due to penicillin-sensitive organisms, where prolonged release is desired.

Dosage and administration For intramuscular injection only.

Adults: 400,000 units (300 mg procaine penicillin G and 60 mg sodium penicillin G) 24-hourly or 12-hourly.

Children: Over 25 kg as for adults; under 25 kg proportionally.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to penicillin or procaine.

Special precautions: Appropriate treatment for systemic reactions should be readily available.

Side-effects: Skin reactions may occur but usually resolve on cessation of therapy; generalised systemic reactions are rare and usually associated with a history of allergy or penicillin intolerance.

The safety of Bicillin Injection during pregnancy has not been established.

Pharmaceutical precautions Store in a cool dry place. Use within five days after reconstitution if stored at room temperature or 14 days if stored at 4°C.

Legal category POM.

Package quantities Boxes of 10 vials and 100 vials each containing 4 mega units (3 g procaine penicillin G and 0.6 g sodium penicillin) per vial.

Further information Upon reconstitution with 7.5 ml Water for Injections BP, each ml of suspension contains 300,000 units (300 mg) procaine penicillin G and 100,000 units (60 mg) sodium penicillin G.

Product licence number 0166/0073.

BROCADOPA* CAPSULES BROCADOPA* TABLETS

Presentation Brocadopa is presented as clear colourless hard gelatine capsules each containing 125 mg, 250 mg or 500 mg Levodopa BP, imprinted 'Brocadopa 125', '250' or '500', and as white uncoated double-scored tablets each containing 500 mg Levodopa BP, imprinted 'Brocadopa 500'. Brocadopa Capsules and Brocadopa Tablets comply with the monographs for Levodopa Capsules BP and Levodopa Tablets BP respectively.

Uses Dopaminergic, for the treatment of all forms of Parkinsonism, except drug-induced (neuroleptic syndrome).

Dosage and administration By oral administration. **Adults:** Initially 250 mg daily in divided doses, increasing by 250 mg every three to four days until optimal response is obtained. This may occur at any level between 1 g and 8 g daily in divided doses after a period of four to six weeks.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indicated in patients receiving monoamine oxidase inhibitors.

Special precautions: Use with caution in patients receiving pyridoxine, hypotensive agents, phenothiazines and butyrophenones, or tricyclic antidepressants, and in patients suffering from heart disease (heart block, myocardial infarct or insufficiency and cardiac arrhythmia), dementia and psychoses, liver disease or pregnancy.

Side-effects: Gastro-intestinal disturbances, such as nausea, vomiting and anorexia, are the commonest side-effects and occur early. They may be diminished by administration after food and by finer fractionation of the daily dose. A non-phenothiazine anti-emetic drug may be given half an hour before each dose.

Hypotension, generally postural in type, may occur, usually unaccompanied by symptoms or change in pulse rate. Smaller dosage increments will reduce the incidence.

Involuntary movements usually occur at higher dosage level, and may be alleviated by a small reduction in dosage of 0.5–1 g daily or by fractionation of dosage.

Psychic manifestations such as restlessness and nervousness may occur with some disturbance of sleep. More rarely, agitation or mania with hallucinations have been reported. Psychiatric side-effects are more likely to occur in patients with a pre-existing psychosis but may be diminished or abolished by reduction or cessation of dosage.

Cardiac disturbances, e.g. paroxysmal tachycardia and arrhythmias, have been reported. It may be advisable to stop dosage and recommence at a lower level.

Overdosage: No reports of overdosage have been received.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities Capsules: 250 × 125 mg, 100 × 250 mg, 250 × 250 mg, 100 × 500 mg and 250 × 500 mg.

Tablets: 100 × 500 mg.

Further information Nil.

BROCADOPA TEMTABS*

Presentation Brocadopa Temtabs are presented as white uncoated double-scored tablets each containing 500 mg Levodopa BP in a special formulation designed to effect a slow release of the active substance, and are imprinted 'Brocadopa Temtab'.

Uses Dopaminergic, for the treatment of all forms of Parkinsonism, except drug-induced (neuroleptic syndrome).

Dosage and administration By oral administration.

Adults: Initially 250 mg daily in divided doses, increasing by 250 mg every three to four days until optimal response is obtained. This may occur at any level between 1 g and 3 g daily in divided doses after a period of four to six weeks.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indicated in patients receiving monoamine oxidase inhibitors.

Special precautions: Use with caution in patients receiving pyridoxine, hypotensive agents, phenothiazines and butyrophenones, or tricyclic antidepressants, and in patients suffering from heart disease (heart block, myocardial infarct or insufficiency and cardiac arrhythmia), dementia and psychoses, liver disease or pregnancy.

Side-effects: Gastro-intestinal disturbances, such as nausea, vomiting and anorexia, are the commonest side-effects and occur early. They may be diminished by administration after food and by finer fractionation of the daily dose. A non-phenothiazine antiemetic drug may be given half an hour before each dose.

Hypotension, generally postural in type, may occur, usually unaccompanied by symptoms or change in pulse rate. Smaller dosage increments will reduce the incidence.

Involuntary movements usually occur at higher dosage level, and may be alleviated by a small reduction in dosage of 0.5–1 g daily or by fractionation of dosage.

Psychic manifestations such as restlessness and nervousness may occur with some disturbance of sleep. More rarely, agitation or mania with hallucinations have been reported. Psychiatric side-effects are more likely to occur in patients with a pre-existing psychosis but may be diminished or abolished by reduction or cessation of dosage.

Cardiac disturbances, e.g. paroxysmal tachycardia and arrhythmias, have been reported. It may be advisable to stop dosage and recommence at a lower level.

Overdosage: No reports of overdosage have been received.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities 100 × 500 mg Temtabs.

Further information Nil.

Product licence number 0166/0050.

BRONTINA* TABLETS

Presentation Brontina Tablets are presented as white, square tablets, single-scored on one side, each containing 1 mg deproline citrate.

Uses In the treatment of asthma and chronic bronchitis, and for the prophylaxis and treatment of hay fever and perennial rhinitis.

Dosage and administration By oral administration. **Adults:** 1 mg twice daily.

Children: Not recommended.

Contra-indications, warnings, etc Contra-indicated in glaucoma and prostatic hypertrophy.

Special precautions: Use with caution in patients with micturition difficulties.

Side-effects: Occasionally dry mouth, blurred vision and micturition difficulties have been reported.

Overdosage: Could be expected to result in the symptoms of anticholinergic and antihistaminic overdosage.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities 100 × 1 mg tablets.

Further information Nil.

Product licence number 0166/5011.

BRONTISOL* AEROSOL

Presentation Brontisol Aerosol is presented as a pressurised aerosol, each 15 ml cartridge containing a suspension of 2 mg/ml depropine citrate and 3 mg/ml isoprenaline hydrochloride in a mixture of inert propellants. Each metered dose contains 0.1 mg depropine citrate and 0.15 mg isoprenaline hydrochloride.

Uses Bronchodilator for the treatment of asthma, asthmatic bronchitis, chronic bronchitis and other respiratory conditions where a combination of spasmolysis and control of secretions is advantageous.

Dosage and administration By inhalation.

Adults: 1–3 inhalations every four to five hours.

Children: 1–2 inhalations every four to five hours.

Not more than 8 inhalations should be taken in any 24-hour period. Brontisol Aerosol should only be given to children on the advice of a doctor and a responsible adult should supervise the administration of the prescribed dose.

Contra-indications, warnings, etc No contra-indications.

Special precautions: Use with caution in the presence of impaired cardiac function, diabetes, hyperthyroidism and hypertension.

Side-effects: These occur infrequently and are seldom severe, but when occurring are those normally associated with the use of sympathomimetic and anticholinergic drugs: dizziness, tachycardia, dry mouth and blurred vision. In practice these side-effects will usually diminish or disappear with continued usage. Dosage adjustments may occasionally be necessary.

Overdosage: Could be expected to result in the symptoms associated with sympathomimetic anticholinergic and antihistaminic overdosage.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities 1 × 15 ml cartridge and mouthpiece.

Further information As the aerosol is pressurised, it must not be punctured, or disposed of by burning.

Product licence number 0166/5000.

CYCLOSPASMOL* SUSPENSION

Presentation Cyclospasmol Suspension is presented as a dry powder, ready for reconstitution at the time of dispensing by the addition of 375 ml distilled water. The resulting suspension provides 90 doses each of 5 ml, each 5 ml dose containing 400 mg cyclandelate.

Uses For the treatment of organic vasospastic peripheral and cerebrovascular diseases associated with impaired circulation, especially in the long-term management of chronic insufficiency and in the sequelae of strokes, and in the improvement of mental function, dementia, confusion etc., and in intermittent claudication, Raynaud's phenomenon, chilblains, night cramps, acrocyanosis, cold hands and feet, etc.

Dosage and administration By oral administration.

Adults: 1,600 mg (20 ml) daily in 2 or 4 divided doses.

Children: A dosage for children has not been established

Contra-indications, warnings, etc Contra-indicated in the acute phase of a cerebrovascular accident.

Special precautions: None.

Side-effects: At very high dosage, nausea, gastro-intestinal distress or flushing may occur.

Overdosage: Gross overdosages have not been reported; theoretically circulatory collapse could occur and treatment would be gastric lavage and, if necessary, vasopressors.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated. Upon reconstitution, Cyclospasmol suspension carries an expiry date of 3 months from the date of reconstitution.

Legal category P.

Package quantities Each bottle, after reconstitution, provides 90 doses each of 400 mg cyclandelate in 5 ml.

Further information Each 5 ml dose contains approximately 500 mg sucrose. For maximum therapeutic effect it is recommended that the daily dose of 1,600 mg be given; maximal therapeutic response may not be seen within the first one or two months of treatment.

Product licence number 0166/0062.

CYCLOSPASMOL* TABLETS CYCLOSPASMOL* CAPSULES

Presentation Cyclospasmol is presented as pink sugar-coated tablets each containing 400 mg cyclandelate, imprinted 'Cyclospasmol'; and as pink/grey hard gelatine capsules each containing 400 mg cyclandelate imprinted 'Cyclospasmol'.

Uses For the treatment of organic vasospastic peripheral and cerebrovascular diseases associated with impaired circulation, especially in the long-term management of chronic insufficiency and in the sequelae of strokes, and in the improvement of mental function, dementia, confusion, etc., and in intermittent claudication, Raynaud's phenomenon, chilblains, night cramps, acrocyanosis, cold hands and feet, etc.

Dosage and administration By oral administration.

Adults: 1,600 mg daily in 2 or 4 divided doses.

Children: A dosage for children has not been established

Contra-indications, warnings, etc Contra-indicated in the acute phase of a cerebrovascular accident.

Special precautions: None.

Side-effects: At very high dosages, nausea, gastro-intestinal distress or flushing may occur.

Overdosage: Gross overdoses have not been reported; theoretically circulatory collapse could occur and treatment would be gastric lavage and, if necessary, vasopressors.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category P.

Package quantities Tablets 250 × 400 mg. Capsules 250 × 400 mg and treatment packs of 112 tablets.

Further information For maximum therapeutic effect, it is recommended that the daily dosage of 1,600 mg be given; maximal therapeutic response may not be seen within the first one or two months of treatment.

Cyclospasmol Capsules 0166/0021
Cyclospasmol Tablets 0166/0052

DE-NOL*

Presentation De-Nol is presented as a clear red liquid, in a 560 ml bottle, containing 120 mg tripotassium dicitrato bismuthate (as Bi_2O_3) in each 5 ml.

Uses Ulcer healing agent. For the treatment of gastric and duodenal ulcers.

Dosage and administration By oral administration.

Adults: 5 ml diluted with 15 ml water four times a day on an empty stomach, half an hour before each of the three main meals and two hours after the last meal of the day. In particularly resistant cases, especially duodenal ulcers, the dosage may be increased to 10 ml diluted with 15 ml water, six times a day, half an hour before and two hours after each of the three main meals. De-Nol should be taken for a minimum period of 28 days and it is important that patients do not miss a dose. In long-standing or resistant cases, a further course of De-Nol therapy may be necessary to achieve maximum therapeutic benefit.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indicated on theoretical grounds in cases of severe renal insufficiency and in pregnancy.

Special precautions: De-Nol may inhibit the efficacy of orally administered tetracyclines.

Side-effects: Blackening of the stool usually occurs and darkening of the tongue has been reported. Electrolyte imbalance does not occur.

Overdosage: No reports of overdosage have been received; gastric lavage and if necessary supportive therapy would be indicated.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category P.

Package quantities Treatment packs of 560 ml.

Further information Some patients with an associated gastritis may experience an initial discomfort.

Product licence numbers
0166/5024

DEPOCILLIN* INJECTION

Presentation Depocillin Injection is presented as vials of dry powder for the preparation of Procaine Penicillin Injection BP. Each vial contains 3 mega units (3 g) of procaine penicillin G.

Uses Antibiotic for the treatment of infections due to penicillin-sensitive organisms, where prolonged release is desired.

Dosage and administration For intramuscular injection only.

Adults: 300,000 units (300 mg) 24-hourly or 12-hourly.

Children: Over 25 kg as for adults; under 25 kg proportionally.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to penicillin or procaine.

Special precautions: Appropriate treatment for systemic reactions should be readily available.

Side-effects: Skin reactions may occur but usually resolve on cessation of therapy; generalised systemic reactions are rare and usually associated with a history of allergy or penicillin intolerance.

The safety of Depocillin Injection during pregnancy has not been established.

Pharmaceutical precautions Store in a cool dry place. Use within five days after reconstitution if stored at room temperature or 14 days if stored at 4°C.

Legal category POM.

Package quantities Boxes of 10 vials and 100 vials each containing 3 mega units (3 g) per vial.

Further information Upon reconstitution with 8 ml Water for Injections BP each ml of suspension contains 300,000 units (300 mg) of procaine Penicillin G.

Product licence number 0166/0072.

DEPOCILLIN* AQUEOUS INJECTION

Presentation Depocillin Aqueous Injection is presented as vials containing 10 ml Procaine Penicillin Injection BP, each ml containing 300,000 units (300 mg) procaine penicillin G.

Uses Antibiotic for the treatment of infections due to penicillin-sensitive organisms, where prolonged release is desired.

Dosage and administration For intramuscular injection only.

Adults: 300,000 units (300 mg) 24-hourly or 12-hourly.

Children: Over 25 kg as for adults; under 25 kg proportionally.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to penicillin or procaine.

Special precautions: Appropriate treatment for systemic reactions should be readily available.

Side-effects: Skin reactions may occur but usually resolve on cessation of therapy; generalised systemic reactions are rare and usually associated with a history of allergy or penicillin intolerance.

The safety of Depocillin Aqueous Injection during pregnancy has not been established.

Pharmaceutical precautions Store below 15°C.

Legal category POM.

Package quantities Boxes of 10 vials and 50 vials each containing 3 mega units (3 g) per vial.

Further information Nil.

Product licence number 0166/0074.

DIDRONEL* TABLETS ▼

Presentation White rectangular tablets, each tablet containing etidronate disodium 200 mg.

Uses Didronel is indicated for the treatment of Paget's disease of bone (osteitis deformans). Effectiveness has been demonstrated primarily in patients with polyostotic Paget's disease with symptoms of pain and with clinically significant elevations of urinary hydroxyproline and serum alkaline phosphatase. In other circumstances in which there is extensive involvement of the skull or the spine with the prospect of irreversible neurological damage, or when a weight-bearing bone may be involved, the use of Didronel may be considered.

Dosage and administration 5 mg/kg/day to 20 mg/kg/day as detailed below.

Adults: The recommended initial dose of Didronel for most patients is 5 mg/kg body weight/day, not to exceed a period of six months. Doses above 10 mg/kg should be reserved for use when there is an overriding requirement for suppression of increased bone turnover associated with Paget's disease or when the patient requires more prompt reduction of elevated cardiac output. Treatment with doses above 10 mg/kg/day should be approached cautiously and should not exceed three months duration. Doses in excess of 20 mg/kg/day are not recommended.

Retreatment should be undertaken only after a drug-free period of at least three months and after it is evident that reactivation of the disease has occurred and biochemical indices of the disease have become substantially re-elevated or approach pretreatment values (approximately twice the upper limit of normal or 75% of pretreatment value). In no case should duration of retreatment exceed the maximum duration of the initial treatment. Premature retreatment should be avoided. In clinical trials the biochemical improvements obtained during drug therapy have generally persisted for a period of three months to, in some cases, up to 2 years after drug withdrawal.

2. Children: Disorders of bone in children, referred to as juvenile Paget's disease, have been reported rarely. The relationship to adult Paget's disease has not been established. Didronel has not been studied in children for Paget's disease.

3. Heterotopic Ossification: In heterotopic ossification complicating hip replacement, the recommended adult dose is 20 mg/kg/day for one month pre-operatively followed by 20 mg/kg/day for three months post-operatively. The total treatment period is four months. There is no evidence that Didronel therapy will affect mature heterotopic bone.

In heterotopic ossification due to spinal cord injury the recommended adult dose of Didronel is 20 mg/kg/day for two weeks followed by 10 mg/kg/day for ten weeks. The total treatment period is twelve weeks. The recommended dosage should be instituted as soon as is medically feasible following the injury, preferably prior to any radiographic evidence of heterotopic ossification.

4. Directions for use: Didronel should be administered as a single, oral dose, two hours before meals. It may be given with fruit juice or water. Food in the stomach or upper portions of the small intestine, particularly materials high in calcium content such as milk, may reduce absorption. Therefore, eating should be avoided for two hours before and after drug administration.

5. Daily dosage guide:

Body Weight		Required Daily Regimen of 200 mg Tablets		
Kilograms	Stones	5 mg/kg*	10 mg/kg*	20 mg/kg†
50	8	1	3	5
60	9½	2	3	6
70	11	2	4	7
80	12½	2	4	8
90	14	2	5	9

* Course of therapy – 6 months. † Course of therapy – 3 months.

Contra-indications, warnings, etc *Contra-indications:* At present, clinical trials have demonstrated no absolute contra-indications to Didronel.

Precautions:

1. General: Didronel retards mineralisation of osteoid laid down during the bone accretion process. This effect is dose and time dependent. There may be an overlap of beneficial and mineralisation inhibition effects in some patients at higher doses. Extended periods of medication should be approached cautiously. When administered at doses of 20 mg/kg/day, Didronel suppresses bone turnover and essentially stops mineralisation of new bone in Pagetic lesions and, to a lesser extent, in the uninvolved skeleton. Mineralisation of Pagetic lesions has been demonstrated to occur normally after discontinuation of the drug.

Patients with Paget's disease of bone should maintain an adequate nutritional status, and particularly, an adequate intake of calcium and vitamin D. Patients with restricted vitamin D and calcium intake may be particularly sensitive to drugs that affect calcium homeostasis and should be closely followed while under treatment with Didronel.

In the treatment of heterotopic ossification, no problems relating to loosening of prosthetic devices have been encountered. The incidence of migration of the trochanter has not been observed to be increased with Didronel therapy.

Didronel is not metabolised but excreted intact via the kidney; therefore, treatment of patients with impaired renal function should be approached very cautiously, if at all.

Didronel therapy has been withheld from patients with enterocolitis because increased frequency of bowel movements and diarrhoea are seen in some patients when Didronel is administered at a dose of 20 mg/kg/day and may be increased occasionally at lower doses.

2. Pregnancy: Reproduction studies have been performed in rats and rabbits. In some of these studies there

was a decrease in the number of live born fetuses. There were no teratogenic effects. Because Didronel does not cross the placental barrier in these species, the decrease in number of live fetuses may have been due to a metabolic effect of Didronel in the mother. There is no experience in pregnant women given Didronel. Didronel should be used only when clearly needed in women who are or may become pregnant.

3. Nursing Mothers: It is not known whether this drug is excreted in human milk. As a general rule, nursing should not be undertaken while the patient is on a drug since many drugs are excreted in human milk.

Warnings: The physician should adhere to the recommended dose regimen in order to avoid overtreatment with Didronel. The response to therapy may be of slow onset and may continue even for months after treatment when the drug has been discontinued. Dosage should not be increased prematurely nor should treatment be resumed before there is clear evidence of reactivation of the disease process. Retreatment should not be initiated until the patient has had at least a three-month drug-free interval.

Increased or recurrent bone pain at existing Pagetic sites and/or the appearance of pain at sites previously asymptomatic has been reported. At the recommended dose (5 mg/kg/day) 1 out of 10 patients reported the phenomena; at higher doses the figure rose to 2 out of 10. In placebo-treated patients, the occurrence was 1 out of 15. In Didronel treated patients, the pain resolved while therapy was continued in some patients but persisted for several months in others.

Fractures are recognised as a common feature in patients with Paget's disease. There has been no evidence of increased risk at the recommended dose of 5 mg/kg/day for six months. The risk of fracture may be increased when Didronel is taken at a dose level of 20 mg/kg/day in excess of three months. This risk may be greater in patients with extensive and severe disease, a history of multiple fractures, and/or rapidly advancing osteolytic lesions. It is recommended that the drug be discontinued when fractures occur and that therapy not be reinstated until fracture healing is complete.

The incidence of osteogenic sarcoma is known to be increased in Paget's disease. Pagetic lesions, with or without therapy, may appear by x-ray to progress markedly, possibly with some loss of definition of periosteal margins. Such lesions should be evaluated carefully to differentiate these from osteogenic sarcoma.

Concomitant fractures are common in patients with spinal-cord injury. In controlled studies, no problems of fracture healing on stabilisation of the spine were encountered. In cases with multiple long bone fractures, it may be advisable to delay therapy for a short time until callus formation is evidenced.

Side-effects: Gastrointestinal complaints such as diarrhoea, loose bowel movement, and nausea are increased in some patients when Didronel is administered at doses greater than 5 mg/kg/day. The incidence is about 1 out of 15 in both placebo-treated patients and in patients on Didronel, 5 mg/kg/day. The incidence rises to approximately 2 out of 10 patients treated with Didronel at the dose of 20 mg/kg/day.

Overdosage: While there is no experience with acute overdosage, it is theoretically possible that enough Didronel could be taken to result in hypocalcaemia. Treatment should be by cessation of therapy, correction of hypocalcaemia with intravenous calcium gluconate

and maintenance of an adequate nutritional status, artificially supplemented if necessary.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities 60 × 200 mg tablets.

Further information Nil.

Product licence number 0166/0101.

DISIPAL* TABLETS DISIPAL* INJECTION

Presentation Disipal Tablets are presented as yellow sugar-coated tablets each containing 50 mg Orphenadrine Hydrochloride BP, imprinted 'Disipal'. Disipal Tablets comply with the monograph for Orphenadrine Hydrochloride Tablets BP.

Disipal Injection is presented as a sterile aqueous solution in clear glass 2 ml ampoules each containing 20 mg/ml Orphenadrine Hydrochloride BP.

Uses Anticholinergic, for the treatment of all forms of Parkinsonism, including drug-induced (neuroleptic syndrome).

Dosage and administration *By oral administration:*

Adults: Initially 150 mg daily in divided doses, increasing by 50 mg every two or three days until maximum benefit is obtained. Optimal dosage is usually 250–300 mg daily in divided doses in idiopathic and post-encephalitic Parkinsonism, 100–150 mg daily in divided doses in arteriosclerotic Parkinsonism, and 150–300 mg daily in divided doses in the neuroleptic syndrome. Maximal dosage, 400 mg daily in divided doses.

Children: As for adults.

By intramuscular injection: **Adults:** 20–40 mg (1–2 ml) as determined by the physician.

Children: As for adults.

Contra-indications, warnings, etc Contra-indicated in patients with glaucoma or prostatic hypertrophy.

Special precautions: Use with caution in patients with micturition difficulties or in pregnancy.

Side-effects: Occasionally dry mouth, disturbances of visual accommodation and micturition difficulties may occur; these usually disappear spontaneously or may be controlled by a slight reduction in dosage.

Overdosage: Toxic effects are anticholinergic in nature and the treatment is gastric lavage, cholinergics such as carbachol, anticholinesterases such as physostigmine and general non-specific treatment.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities *Tablets:* 100 × 50 mg, 250 × 50 mg, 1,000 × 50 mg, 10,000 × 50 mg.

Ampoules: 10 × 40 mg/2 ml.

Further information Although very rarely reported, there may be provocation of dextropropoxyphene side-effects when that drug is administered concurrently with orphenadrine.

Product licence numbers

Tablets 0166/5001

Injection 0166/5005

ELAMOL* CAPSULES

Presentation Elamol Capsules are presented as grey/orange hard gelatine capsules each containing 80 mg tofenacin hydrochloride, imprinted 'Elamol'.

Uses Antidepressant, for the treatment of mild to moderate depression in the older patient.

Dosage and administration By oral administration.

Adults: Up to 240 mg daily in divided doses as directed by the physician.

Children: Not recommended.

Contra-indications, warnings, etc Contra-indicated in patients with glaucoma or prostatic hypertrophy, or having suicidal tendencies or requiring ECT, or being pregnant; also in patients receiving monoamine oxidase inhibitors. Patients receiving MAOIs should discontinue therapy and allow a period of two weeks to elapse before instituting therapy with Elamol.

Special precautions: Use with caution in patients with micturition difficulties or patients who are receiving other antidepressant drugs or tranquillisers where concurrent administration of Elamol is considered desirable.

Side-effects: Occasionally dry mouth, disturbances of visual accommodation and tremor may occur; these usually disappear spontaneously or may be controlled by a slight reduction in dosage. Other side-effects which have been reported are gastro-intestinal disturbances, drowsiness, vertigo, agitation and skin rashes.

Overdosage: There have been no reports of overdosages; toxic effects would be anticholinergic in nature and the treatment would be gastric lavage, cholinergics such as carbachol, anticholinesterases such as physostigmine and general non-specific treatment.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities Capsules 100 x 80 mg.

Further information Nil.

Product licence number 0166/0001.

**LOCOID* CREAM
LOCOID* OINTMENT**

Presentation Locoid Cream, containing 0.1% hydrocortisone 17-butyrate in a cream base.

Locoid Ointment, containing 0.1% hydrocortisone 17-butyrate in an ointment base.

Uses The products are recommended for clinical use in the treatment of conditions responsive to topical corticosteroids, e.g. eczema, dermatitis and psoriasis.

The products are intended for topical application.

Dosage and administration For adults and children, to be applied to the affected part two to four times a day, or as directed by the physician.

Where necessary, application may be made under an occlusive dressing.

Contra-indications, warnings, etc These preparations are contra-indicated in the presence of viral or fungal infections, tubercular or syphilitic lesions, and in bacterial infections unless used in conjunction with appropriate chemotherapy. Contact with the eye should be avoided.

In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur, even without occlusion.

Pharmaceutical precautions Store under normal pharmaceutical conditions of storage.

Legal category POM.

Package quantities *Locoid Cream:* Tubes of 30 g and 100 g.

Locoid Ointment: Tubes of 30 g and 100 g.

Further information Locoid is a non-fluorinated topical steroid. Whilst clinical trials have shown it to be as effective as the potent fluorinated steroids, in clinical practice there is a low incidence of reported clinical side-effects.

Product licence numbers

Locoid Cream 0166/0058

Locoid Ointment 0166/0059

**LOCROID* C CREAM
LOCROID* C OINTMENT**

Presentation Locoid C cream, containing 0.1% hydrocortisone 17-butyrate and 3% chlorquinaldol, in a cream base.

Locoid C ointment, containing 0.1% hydrocortisone 17-butyrate and 3% chlorquinaldol, in an ointment base.

Uses The products are recommended for clinical use in the treatment of conditions responsive to topical corticosteroids, e.g. eczema, dermatitis and psoriasis, where secondary bacterial or fungal infection is present or suspected, or may complicate the condition.

The products are intended for topical application.

Dosage and administration For adults and children, to be applied to the affected part two to four times a day, or as directed by the physician, until the infection has resolved. If the underlying dermatological condition still persists, treatment may be continued with Locoid cream or ointment.

Contra-indications, warnings, etc *Contra-indications:* These preparations are contra-indicated in the presence of viral, tubercular or syphilitic lesions. Contact with the eye should be avoided.

Warnings: In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur, even without occlusion.

Occlusive dressings are not recommended in the presence of infections.

Locoid C preparations should not be used for longer than 14 days at a time, nor should more than 60 g be applied during this period.

Pharmaceutical precautions Store under normal pharmaceutical conditions of storage.

Legal category POM.

Package quantities *Locoid C cream*: Tubes of 30 g.

Locoid C ointment: Tubes of 30 g.

Further information Locoid is a non-fluorinated topical steroid. Whilst clinical trials have shown it to be as effective as the potent fluorinated steroids, in clinical practice there is a low incidence of reported side-effects.

Chlorquinaldol is an effective topical antibacterial and antimycotic.

Product licence numbers

Locoid C ointment 0166/0057

LOCOID* SCALP LOTION

Presentation Locoid Scalp Lotion contains 0.1% hydrocortisone 17-butyrate in an iso-propyl alcohol/water base, specially formulated for the treatment of skin disorders of the scalp.

Uses In the treatment of steroid-responsive dermatoses of the scalp, including seborrhoea capitis with or without an associated severe dandruff.

Dosage and administration Apply twice daily to the scalp, or as directed.

Contra-indications, warnings, etc These preparations are contra-indicated in the presence of viral or fungal infections, tubercular or syphilitic lesions, and in bacterial infections unless used in conjunction with appropriate chemotherapy. Contact with the eye should be avoided.

In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur, even without occlusion.

Pharmaceutical precautions Store under normal pharmaceutical conditions of storage.

Legal category POM.

Package quantities Plastic squeeze bottles of 20 ml and 100 ml.

Further information Locoid lotion should be kept away from the eyes, and not used near a fire or naked flame.

Product licence number 0166/0060.

MEDITAR* STICK

Presentation Meditar Stick is presented as a 20 g greenish-brown stick in a twist-up plastic container. The stick consists of a wax base containing 5% coal tar.

Uses Topical treatment of psoriasis and eczema mainly in chronic phases.

Dosage and administration Apply to the affected area once or twice daily or as directed by the physician. When used in conjunction with U.V.B. light, the tar should be removed before exposure to U.V.B. The Meditar Stick softens on contact with skin enabling a thin layer to be applied lightly and accurately to the affected area.

Contra-indications, warnings, etc The use of Meditar is not recommended in generalised pustular psoriasis, infections of the skin or in patients allergic to coal tar.

Coal tar can sensitise the skin to U.V. light which can lead to sunburn. Coal tar should, therefore, be used cautiously in sunlight.

Pharmaceutical precautions Keep in a cool place.

Legal category P.

Package quantities 20 g containers.

Further information Nil.

Product licence number 0166/0106.

PIMAFUCIN* CREAM

Presentation Pimafucin Cream is presented as a white cream in 25 g tubes containing 20 mg/g natamycin (2%).

Uses Antifungal antibiotic for the treatment of candidal infections of the anus, genitalia, skin, nails and oral mucosa, and acute fungal skin infections.

Dosage and administration By topical application.

Adults: Apply two to three times a day. (In cases of chronic paronychia and onychia treatment must continue for several months to prevent relapses.)

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: None.

Special precautions: None.

Side-effects: None have been reported.

Overdosage: Has not been reported.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities Tubes 25 g.

Further information Nil.

Product licence number 0166/5009.

PIMAFUCIN* 1% SUSPENSION

Presentation Pimafucin 1% Suspension is presented as a cream-white sterile suspension in ready-to-use 5 ml dropper bottles containing 10 mg/ml natamycin.

Uses Antifungal antibiotic for the treatment of oral thrush (due to *Candida albicans*) and also for mouth ulcers secondarily infected with *Candida albicans*.

Dosage and administration By local oral administration.

Infants: 4 drops under the tongue after every feed.

Children and adults: 10 drops after each meal, preferably directly on to the lesions.

Contra-indications, warnings, etc

Contra-indications: None.

Special precautions: None.

Side-effects: None have been reported.

Overdosage: Has not been reported.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated. Store away from light.

Legal category POM.

Package quantities 5 ml dropper/dispenser.

Further information Nil.

Product licence number 0166/0047.

PIMAFUCIN* 2½% SUSPENSION

Presentation Pimafucin 2½% Suspension is presented as a cream-white sterile suspension in a clear glass 20 ml vial, containing 25 mg/ml natamycin (2½%).

Uses Antifungal antibiotic for the treatment of infections of the lungs and respiratory tract caused by fungi and yeasts, particularly *Aspergillus* spp. and *Candida albicans*.

Dosage and administration By inhalation.

Adults: 2.5 mg natamycin three times a day for four weeks and 2.5 mg twice a day thereafter until a consistently negative sputum culture for the causative organism is obtained. A minimum total treatment period of six weeks is usually necessary. Administration must be made by a power nebuliser. The suspension should be diluted with sterile physiological saline or a sterile mucolytic preparation, and used within 48 hours of preparation.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: None.

Special precautions: None.

Side-effects: None have been reported.

Overdosage: Has not been reported.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities Vials 20 ml.

Further information Nil.

Product licence number 0166/5010.

PIMAFUCIN* VAGINAL TABLETS

Presentation Pimafucin Vaginal Tablets are presented as creamy-white ovoid vaginal tablets, each containing 25 mg natamycin, imprinted 'Pimafucin'.

Uses Antifungal antibiotic with antitrichomonal activity, for the treatment of vaginal irritation and discharge whether due to candidal, trichomonal or mixed infections.

Dosage and administration By intravaginal administration.

Candida Albicans: One Tablet should be inserted at night, and one in the morning for a total of ten days. Alternatively, one tablet to be inserted nightly for a total of 21 nights.

Trichomonas Vaginalis: One tablet to be inserted nightly for a total of 21 nights.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: None.

Special precautions: Insert with care during pregnancy.

Side-effects: Occasionally local irritation may occur.

Overdosage: Has not been reported.

Pharmaceutical precautions Normal pharmaceutical storage and handling are indicated.

Legal category POM.

Package quantities Vaginal tablets 20 × 25 mg with applicator.

Further information Nil.

Product licence number 0166/5008.

BETIM*

Presentation White, flat circular tablets engraved with '102' on the scored face and with an Assyrian lion on the reverse. Each tablet contains timolol maleate 10 mg.

Uses *Mode of Action:* Betim is a beta-adrenergic receptor blocking agent. It competitively antagonises the action of adrenergic transmitters on beta receptors and thus blocks beta-sympathomimetic activity in the heart, the bronchi and blood vessels.

Betim is considered to be a highly specific beta-adrenergic blocking drug since it does not block the chronotropic or inotropic effects of calcium, glucagon, theophylline or digitalis. It does not have significant local anaesthetic or direct myocardial depressant activity nor any significant beta-adrenergic stimulant effect.

Betim reduces heart rate, force of myocardial contractions and myocardial oxygen consumption. The modification of the cardiac response to stress or exercise is therapeutically useful in angina pectoris.

Betim is also of therapeutic value in hypertension although the mechanism of action is unclear.

Betim is rapidly absorbed from the gut. Its beta blocking activity is apparent within thirty minutes of administration and has been shown to last for up to 24 hours.

Indications: Betim is indicated in angina pectoris due to ischaemic heart disease and for the treatment of hypertension and to reduce mortality and reinfarction in patients surviving acute myocardial infarction. Betim is also indicated in the prophylactic treatment of patients with common and classic migraine in which it effectively reduces the incidence of attacks.

Dosage and administration *For angina and hypertension:* The recommended dose range is 10–60 mg per day. Therapy should begin with a dose of 10 mg daily increasing, if necessary, in steps of 10 mg at intervals of 3–4 days.

Most hypertensive patients will be controlled by 10–30 mg timolol which can be administered once daily or in divided doses if preferred. The dose of Betim may need adjustment when used in conjunction with other antihypertensive drugs.

In angina, Betim should be administered in divided doses.

After myocardial infarction: Start with 5 mg ($\frac{1}{2}$ tablet) twice daily for two days. If there are no adverse reactions, increase dosage to 10 mg twice daily and maintain at this dose.

For the prophylactic treatment of common and classic migraine: 10 to 20 mg once daily or in two divided doses.

Contra-indications, warnings, etc *Contra-indications:* Heart failure, unless adequately controlled. Sinus bradycardia or heart block. Cardiogenic shock. Bronchial asthma, chronic obstructive pulmonary disease. Anaesthesia with agents that produce myocardial depression, such as chloroform and ether. Pregnancy.

Precautions: Although Betim has no direct myocardial depressant activity, the continued depression of sympathetic drive through beta-blockade may lead to cardiac failure. All patients should be observed for evidence of cardiac failure, and, if it occurs, digitalisation and diuretic therapy should be considered.

Betim should be administered with caution to patients subject to spontaneous hypoglycaemia or diabetic patients who are on insulin or oral hypoglycaemic agents.

Beta-adrenergic blockers may mask the premonitory signs and symptoms of acute hypoglycaemia.

Caution is recommended when Betim is administered to patients on catecholamine depleting drugs such as reserpine or guanethidine.

Betim should be administered with caution to patients with impaired renal function or impaired hepatic function. Parasthesiae and coldness of the limb extremities have also been reported.

Side-effects: Gastro-intestinal symptoms (e.g. epigastric distress, nausea, vomiting, diarrhoea), dizziness, insomnia, sedation, depression, weakness, dyspnoea, bradycardia, heart block, bronchospasm and heart failure.

Warning: There have been reports of skin rashes, and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with the beta-blocker should be gradual.

Overdosage: The most common signs of overdosage are bradycardia, hypotension, bronchospasm, and acute cardiac failure.

Suggested treatments are as follows:

Severe bradycardia: I.V. atropine sulphate 0.25–2 mg. If bradycardia persists, I.V. isoprenaline 25 mcg may be given.

Severe hypotension: I.V. noradrenaline or adrenaline.

Bronchospasm: Isoprenaline hydrochloride, orciprenaline or salbutamol.

Acute cardiac failure: Digitalis, diuretics and oxygen. In refractory cases I.V. aminophylline and I.V. glucagon 0.5–1 mg have been reported useful.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Packs of 100 tablets.

Further information Timolol maleate crosses the placenta and appears in breast milk.

Product licence number 0748/0015

CENTYL* TABLETS

Presentation *Tablets 2.5 mg:* Each contains 2.5 mg Bendrofluazide BP, white uncoated tablets, no coding marks.

Tablets 5 mg: Each contains 5 mg Bendrofluazide BP, white uncoated tablets, circular groove embossed on one face and score line on other.

Uses *Mode of Action:* Centyl contains the diuretic bendrofluazide, which is as effective as chlorothiazide at 100th the dose and produces a more prolonged diuresis. The diuresis is usually complete in 12–18 hours. In common with other thiazides, it increases the renal excretion of sodium, chloride and to a lesser extent potassium ions, together with an accompanying volume of water.

Indications: *Hypertension:* Control of blood pressure in mild and in some cases of moderate hypertension.

Oedema: Oedema of cardiac, hepatic or renal origin. Pre-menstrual oedema. Toxaemia of pregnancy. Oedema induced by use of steroids.

Dosage and administration *Adults:* Initially, 5–10 mg bendrofluazide once daily. Maintain with 2.5–10 mg daily. Centyl should be taken in the morning to avoid nocturia.

Children: Pro rata, according to age and body weight.

Contra-indications, warnings, etc *Contra-indications:* Anuria. Centyl should not be used in patients with renal failure or with a history of hypersensitivity to thiazides. As with other diuretics, Centyl should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Precautions: Thiazide diuretics should be used with caution in patients with renal or hepatic dysfunction. Fluid and electrolyte levels should be measured in patients undergoing prolonged or intense diuresis as potassium depletion may occur and potassium supplements may be needed. Potassium depletion is a particular danger to digitalised patients or those with hepatic cirrhosis with ascites. Periodic testing for urine glucose is advisable in patients with latent or overt diabetes. The dose of hypoglycaemic agents in diabetic patients may require adjustment.

Adverse Reactions: Thiazide diuretics may cause excessive depletion of fluid and electrolytes during prolonged or intense use. Symptoms are muscle pain or fatigue, thirst, gastro-intestinal upset and oliguria. Hypokalaemia is most severe in patients already depleted of potassium, as in renal or hepatic insufficiency.

Coma may be precipitated in hepatic cirrhosis.

The thiazide diuretics may induce hyperglycaemia and glycosuria in diabetic and other susceptible patients. This is usually reversible if the treatment is stopped. Hyperuricaemia sometimes occurs but an attack of gout is rare. The thiazide diuretics increase blood urea which

is most pronounced in patients with renal disease and pre-existing retention of nitrogen.

Reports of other adverse reactions include skin rashes with associated photosensitivity, necrotising vasculitis, acute pancreatitis, blood dyscrasias and aggravation of pre-existing myopia.

Pregnancy: Thiazide diuretics cross the placenta and are secreted in breast milk.

Overdosage: General measures to restore blood volume, maintain blood pressure and correct electrolyte imbalance.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence numbers

Tablets 2.5 mg 0748/5901

Tablets 5 mg 0748/5902

CENTYL* K

Presentation Each tablet contains Bendrofluazide BP (Centyl) 2.5 mg and Potassium Chloride BP 573 mg (7.7 mmol potassium in a slow-release wax core). Green ovoid tablets. No identification marks.

Uses *Mode of Action:* Centyl K is a combination of the diuretic bendrofluazide with a potassium supplement.

Bendrofluazide is as effective as chlorothiazide at 100th the dose and produces a more prolonged diuresis, which is usually complete in 12–18 hours. In common with other thiazides, it increases the renal excretion of sodium, chloride and, to a lesser extent, potassium ions together with an accompanying volume of water. Potassium depletion is frequently associated with prolonged diuretic therapy; a potassium supplement is therefore included in Centyl K. This should minimise potassium depletion.

Because of the risk of localised high concentrations of potassium salts in the small bowel, potassium is included in an inert wax core, from which it is released slowly over several hours. Bendrofluazide is contained in a shell which surrounds the central core.

Indications: *Oedema:* Oedema of cardiac, hepatic or renal origin. Toxaemia of pregnancy.

Hypertension: Control of blood pressure in mild and in some cases of moderate hypertension.

Renal calcium stones: Prophylaxis against recurrent renal calcium stones.

Dosage and administration *Oedema and Hypertension:* Initially 2–4 tablets daily. Maintain with 1–4 tablets daily or on alternate days. Centyl K should be taken in the morning to avoid nocturia.

For renal calcium stones: 2–3 tablets daily.

Contra-indications, warnings, etc *Contra-indications:* Anuria. As with other diuretics, Centyl K should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Precautions: Thiazide diuretics should be used with caution in patients with renal or hepatic dysfunction. Fluid and electrolyte levels should be measured in patients undergoing prolonged or intense diuresis. Even

though Centyl K contains a potassium supplement, depletion may occur, which is of particular danger to digitalised patients or those with hepatic cirrhosis with ascites.

Periodic testing for urine glucose is advisable in patients with latent or overt diabetes. The dose of hypoglycaemic agents in diabetic patients may require adjustment. Thiazide diuretics are used to treat hypertension. Therefore it may be necessary to reduce the dose of other hypotensive agents, e.g. reserpine, hydralazine, β -blocking agents and ganglion blocking agents, when used with Centyl K.

Non-specific small bowel lesions characterised by stenosis and possibly accompanied by ulceration have been associated with the oral administration of tablets and capsules containing potassium salts. Symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such a preparation immediately.

Adverse Reactions: Thiazide diuretics may cause excessive depletion of fluid and electrolytes during prolonged or intense diuresis. Symptoms are muscle pain or fatigue, thirst and dry mouth, gastro-intestinal upset and oliguria. Hypokalaemia is most severe in patients already depleted of potassium, as in renal or hepatic insufficiency. Coma may be precipitated in hepatic cirrhosis. The thiazide diuretics may induce hyperglycaemia and glycosuria in diabetic and other susceptible patients. This is usually reversible if treatment is stopped.

Hyperuricaemia sometimes occurs, but an attack of gout is rare. The thiazide diuretics may increase blood urea, which is most pronounced in patients with renal disease and pre-existing retention of nitrogen.

Reports of other adverse reactions include skin rashes with associated photosensitivity, necrotising vasculitis, acute pancreatitis, blood dyscrasias and aggravation of pre-existent myopia.

Pregnancy: Thiazide diuretics cross the placenta and are secreted in breast milk.

Overdosage: General measures to restore blood volume, maintain blood pressure and correct electrolyte imbalance.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Packs of 100, 500 and 1,000 tablets.

Further information Nil.

Product licence number 0748/5903.

HEPARIN (MUCOUS) INJECTION BP

Presentation Heparin (Mucous) Injection BP 1,000 units per ml: each ml contains 1,000 units sodium heparin. (Presented in 5 ml ampoules without preservative, and 5 ml vials with preservative.)

Heparin (Mucous) Injection BP 5,000 units per ml: each ml contains 5,000 units sodium heparin.

Heparin (Mucous) Injection BP 25,000 units per ml: each ml contains 25,000 units sodium heparin.

Uses *Mode of Action:* Heparin is a naturally occurring anticoagulant which prevents the coagulation of blood in-vivo and in-vitro. It potentiates the inhibition of several activated coagulation factors, including thrombin and factor X.

The anticoagulant properties of heparin are valuable for the prophylaxis and management of intravascular clotting and embolism. It is also used in extra-corporeal circulation i.e. heart-lung and renal dialysis machines and blood transfusions.

In addition to the anticoagulant properties heparin also has some lipaemia-clearing effect which may be utilised in the treatment of fat embolism.

Indications: Treatment of thromboembolic disorders such as: deep vein thrombosis, thrombophlebitis, pulmonary embolism, fat embolism.

Dosage and administration Heparin is usually administered by intravenous injection or subcutaneously. Although the intramuscular route can be used, it is not recommended because of the high incidence of haematomata.

The increase in clotting time provided by heparin becomes apparent immediately after administration and lasts for 4 to 6 hours after intravenous injection and for about eight hours after subcutaneous injection.

Dosage: Intravenous administration: 5,000–10,000 units every 4 hours either by bolus injection or continuous infusion in Sodium Chloride Injection or Dextrose Injection. However, the dose should be monitored with coagulation tests, and varied according to individual response.

Subcutaneous administration: 5,000 units every eight hours.

The treatment period varies from 7–10 days in peri-operative prophylaxis to as much as 6 weeks in the treatment of established thrombosis.

Contra-indications, warnings, etc *Contra-indications:* Haemorrhagic disorders and patients with an actual or potential bleeding site, e.g. peptic ulcer.

Precautions: Heparin therapy should be given with caution to patients about to undergo surgery, and those with impaired renal or hepatic function.

Overdosage: The effect of heparin can be reversed immediately by intravenous administration of a 1% protamine sulphate solution. The quantity of protamine required for neutralisation falls rapidly with the lapse of time after the administration of heparin and can be accurately determined by titration of the patient's plasma, containing heparin, with protamine. If given within 15 minutes of the heparin injection 10 mg of protamine will neutralise 1,000 units of heparin, while 30 minutes after the heparin injection, only 5 mg of protamine per 1,000 units of heparin is needed.

It is important to avoid overdosage of protamine sulphate because protamine itself has anticoagulant properties. A single dose of protamine sulphate should never exceed 50 mg. Intravenous injection of protamine may cause a sudden fall in blood pressure, bradycardia, dyspnoea and transitory flushing, but these may be avoided or diminished by slow and careful administration.

Pharmaceutical precautions Store below 25°C. Admixture of heparin with solutions of other medicinal products may result in precipitation or loss of potency.

Legal category POM.

Package quantities Heparin 1,000 units per ml: 5 ml ampoules (without preservative), 5 ml vials (with preservative). Packs of 5.

Heparin 5,000 units per ml: 5 ml. Packs of 5 vials.

Heparin 25,000 units per ml: 5 ml: 1 vial.

Further information Preservative used: 1,000 units (with preservative) and 5,000 units: 0.5% Chlorbutol. 25,000 units: 0.4% Chlorbutol.

Menstruation and pregnancy are not contra-indications to heparin therapy. Heparin does not cross the placenta or appear in breast milk.

Available for low dose prophylactic use: single dose ampoules containing 5,000 units sodium heparin in 0.2 ml.

Product licence numbers

1,000 units (with preservative)	0748/0007
1,000 units (without preservative)	0748/0040
5,000 units	0748/0008
25,000 units	0748/0009

HEPARIN (MUCOUS) INJECTION BP

5,000 units in 0.2 ml (25,000 units per ml).

Presentation Single dose ampoules containing sodium heparin 5,000 units in 0.2 ml (Preservative: 0.4% Chlorbutol).

Uses *Mode of Action:* Heparin is an anticoagulant which, even in low doses, prevents the formation of thrombin by accelerating the neutralisation of activated factor X by naturally occurring inhibitors.

Indications: Prophylaxis against deep vein thrombosis and thromboembolic events in susceptible patients.

Dosage and administration Administration is by subcutaneous injection. Patients undergoing surgery: 5,000 units in 0.2 ml should be given 2 to 6 hours preoperatively and every 8 hours postoperatively for 10–14 days, or until ambulation, whichever is the longer.

Other patients: 5,000 units in 0.2 ml should be given every 8–12 hours.

Contra-indications, warnings, etc Low doses of heparin, administered as recommended above, do not cause alterations in clotting times in most patients, but occasionally local haematomata may occur at injection sites.

Patients with haemorrhagic disorders may experience bleeding, especially from surgical wounds. The relative risks and benefits of heparin administration in these patients should be assessed carefully. Oral anticoagulants or drugs which interfere with platelet function, e.g. aspirin and dextran solutions, should be administered with caution.

Overdosage: If bleeding should occur, the effect of heparin can be reversed immediately by intravenous administration of a 1% protamine sulphate solution. The dose of protamine sulphate required for neutralisation should be determined accurately by titrating with the patient's plasma.

Pharmaceutical precautions Store below 25°C. Admixture of heparin with solutions of other medicinal products may result in precipitation or loss of potency.

Legal category POM.

Package quantities 15 ampoules of 0.2 ml.

Further information Menstruation and pregnancy are not contraindications to heparin therapy. Heparin does not cross the placenta or appear in breast milk.

Heparin (Mucous) Injection BP is also available in

strengths of 1,000 units per ml (with and without preservative), 5,000 units per ml and 25,000 units per ml.

Product licence number 0748/0011

NATUDERM*

Presentation Natuderm is a white cream. The cream is a stable ambiphilic emulsion system.

Composition: The lipid component (about 35% of total product) contains approximately:

Free fatty acids	14.26%
Squalene	9.4%
Squalane	1.41%
Waxes	19.97%
Sterol Esters	3.81%
Free Sterols	2.37%
Glycerides	44.27%
Phospholipids	0.48%
dl- α -tocopherol	0.0085%
Butylated Hydroxyanisole	0.0085%
Span 60 Sorbitan Monostearate	2.71%
Phenonip	1.27%

The aqueous component (about 65% of total product) contains approximately:

Glycerol	5.63%
Polyoxyethylene Sorbitan Monostearate	1.64%
De-ionised water	92.2%
Phenonip	0.46%

Uses Natuderm is an emollient and protective cream. It has a lipid component similar in composition to human sebum.

Its uses include conditions where skin film emulsion deficiency is a factor.

Indications: As a moisturising emollient and protective for general dermatological use where the secretion of skin film emulsion is deficient.

Dosage and administration A thin application of the cream should be made to the affected area three times daily or as required. It should be rubbed gently into the skin. When used as a protective cream, Natuderm should be applied sparingly to areas of skin at risk, just before or immediately after exposure to potentially harmful factors.

Contra-indications, warnings, etc For external use only. Natuderm is entirely compatible with skin physiology and does not contain unmodified lanolin.

Contra-indications: Nil.

Side-effects: Hypersensitivity is a rare possibility.

Overdosage: Not applicable.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Jars of 40 g and 450 g and tubes of 100 g.

Further information Nil.

Product licence number 0748/0001.

PONDOCILLIN* TABLETS ▼

PONDOCILLIN* SUSPENSION ▼

Presentation *Tablets:* Each tablet contains 500mg pivampicillin – a white film-coated ovoid tablet with the number 128 printed on one side and an Assyrian Lion on the other.

Suspension: Bottles containing powder for the preparation of 50 ml and 100ml suspension. When reconstituted each 5 ml contains 162 mg pivampicillin.

Uses Pondocillin (pivampicillin) is the pivaloyloxy-methyl ester of ampicillin, and is rapidly hydrolysed in the body to ampicillin by non-specific enzymes present in serum, gastro-intestinal mucosa and other tissues.

After oral administration of Pondocillin, the plasma levels of ampicillin are 2–3 times higher than those obtained with equimolar doses of oral ampicillin. The tablets are formulated to disintegrate readily and produce rapid therapeutic plasma levels. A peak level generally occurs after 1 hour compared to approximately 2 hours with oral ampicillin. These levels are comparable to those obtained with an equimolar dose of intramuscular ampicillin.

Concentrations achieved in the urine are similarly raised. Generally, twice the amount of antibiotic can be recovered after treatment with Pondocillin when compared with equimolar doses of oral ampicillin. Whereas between 30–40% of the administered dose appears in the urine in the first 6 hours after oral administration of ampicillin, 70% can be recovered after an equimolar dose of Pondocillin.

Pondocillin is stable in the presence of gastric acid, and, unlike oral ampicillin, absorption is not affected by the presence of food. Plasma concentrations achieved in the post-prandial state do not differ significantly when compared with the fasting state. Like ampicillin, Pondocillin is destroyed by penicillinase-producing bacteria.

Indications: Like ampicillin, Pondocillin has a broad spectrum of activity against both gram-negative and gram-positive organisms. It is particularly indicated for the treatment of infections caused by susceptible strains of *Shigella*, *Salmonella*, *N. gonorrhoea*, *Esch. coli*, *H. influenzae*, *Pr. mirabilis* and is also indicated for pneumococcal, streptococcal and non-penicillinase-producing staphylococcal infections.

Specific infections include:

- (a) Acute and chronic bronchitis
- (b) Pneumonia
- (c) Ear, nose and throat infections
- (d) Gynaecological infections
- (e) Urinary tract infections
- (f) Skin and soft tissue infections
- (g) Gonorrhoea

Dosage and administration *Tablets:* Usual dosage for adults: 500 mg pivampicillin to be administered twice daily. Dosage may be doubled in cases of severe infection. Gonorrhoea: 1.5–2 g pivampicillin as a single dose. 1 g probenecid can be given concurrently as desired. The medication may be taken with food or fluids.

Suspension: Infants under 1 yr: 40–60 mg/Kg body-weight per day.

Children aged 1–5 yrs: 10–15 ml per day

Children aged 6–10 yrs: 15–20 ml per day

Adults and children over 10 yrs: 30ml per day.

The daily dosage may be given either as 2 or 3 equal divided doses.

Dosage may be doubled where appropriate.

Contra-indications, warnings, etc *Contra-indications:* Pondocillin is contra-indicated in any patient with a history of hypersensitivity to any of the penicillins or cephalosporins. Because of the high frequency of exanthemata associated with ampicillin therapy in infectious mononucleosis, treatment with Pondocillin is contra-indicated in this disease.

Pondocillin is also contra-indicated in infections caused by penicillinase producing bacteria.

Precautions: Care should be exercised when treating patients with a history of sensitivity to a variety of allergens, since serious hypersensitivity (anaphylactic) reactions are more likely to occur. If lymphatic leukaemia is treated with Pondocillin then caution is urged because of the frequency of exanthemata associated with ampicillin therapy.

The use of concurrent antacid therapy with Pondocillin is not recommended, since it reduces absorption of the antibiotic, and may cause underdosing.

During long-term therapy it is advisable to carry out routine liver and kidney function tests.

Pregnancy: In keeping with current practice use during the first trimester of pregnancy should be avoided. Ampicillin crosses the placenta and small amounts have been detected in breast milk.

Adverse Reactions: Pondocillin is a compound of low toxicity. Like ampicillin, skin rashes of two types have been noted: a non-specific erythema which usually disappears during treatment, and urticaria which may cause withdrawal of the drug. Anaphylactic reactions have occurred as with other penicillins.

Upper gastro-intestinal disturbances, such as nausea, vomiting, retrosternal pain and flatulence have occurred more frequently when a dose has been given on an empty stomach. Diarrhoea has been reported, but less frequently than with ampicillin. This observation underlines the importance of giving Pondocillin with or just after a meal. None of these effects appear to be dose-related. Other side effects reported are dizziness and pruritis.

Warning: Pondocillin suspension is not recommended for the treatment of severe infections in infancy.

Overdosage: There is no experience of overdosage with Pondocillin. However, excessive doses of Pondocillin are likely to induce nausea, vomiting and gastritis. Treatment should be restricted to symptomatic and supportive measures.

Pharmaceutical precautions *Tablets:* Nil.

Suspension: Pondocillin suspension when reconstituted, is stable for 14 days at room temperature or for 4 weeks when kept in a refrigerator.

Legal category POM.

Package quantities *Tablets:* Bottles of 100 and 20 tablets.

Suspension: Available in amber bottles making 50 ml and 100 ml suspension when dispensed.

Further information Nil.

Product licence numbers

Tablets 0748/0019

Suspension 0748/0020

TENAVOID* TABLETS

Presentation Each tablet contains Bendrofluazide BP 3 mg, Meprobamate BP 200 mg. Orange, ovoid coated tablets. No identification marks.

Uses *Mode of Action:* Bendrofluazide is an effective diuretic which alleviates the mastalgia and abdominal and pelvic discomfort often associated with the premenstrual tension syndrome.

Meprobamate is included to minimise the psychological component of the syndrome.

Indications: Pre-menstrual tension.

Dosage and administration *Adults:* 1 tablet three times daily beginning five to seven days before the expected onset of the period.

Contra-indications, warnings, etc *Contra-indications:* Because of the meprobamate content, Tenavoid should not be used in epileptic patients or in patients in whom habituation to meprobamate has occurred.

As with other diuretics, Tenavoid should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Pregnancy:

Tenavoid should not be used in patients with a history of hypersensitivity to the active ingredients.

Precautions: Because Tenavoid is used intermittently electrolyte disturbance is uncommon. However, it may be desirable to monitor serum electrolytes, particularly serum potassium, in patients undergoing regular Tenavoid therapy. Potassium supplements may be particularly necessary in digitalised patients.

Periodic testing for urine glucose is advisable in patients with latent or overt diabetes. The dose of hypoglycaemic agents in diabetic patients may need adjustment.

Adverse Reactions: Prolonged courses of thiazides may cause depletion of fluid and electrolytes, but these

symptoms should normally not occur during the intermittent treatment of premenstrual tension.

Coma may be precipitated in hepatic cirrhosis. The thiazide diuretics may induce hyperglycaemia and glycosuria in diabetic and other susceptible patients. This is usually reversible if treatment is stopped. Hyperuricaemia sometimes occurs, but an attack of gout is rare.

Skin rashes with associated photosensitivity, necrotising vasculitis, acute pancreatitis, blood dyscrasias and aggravation of pre-existent myopia have been reported.

Drowsiness is the most common adverse effect of meprobamate use. Other effects include skin rashes, headache, nausea, vomiting, blood disorders and hypotension. Habituation to meprobamate and precipitation of epileptic convulsions on withdrawal of the drug have been reported.

Overdosage: For bendrofluazide general measures should be taken to restore blood volume, maintain blood pressure and correct electrolyte disturbance.

With reference to the meprobamate content, raise the urine flow rate by increasing diuresis or by using haemodialysis in severe cases of overdosage.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Pack of 24 tablets.

Further information Both bendrofluazide and meprobamate cross the placenta and are detected in cord blood and breast milk.

Product licence number 0748/5900

**Trade Mark*

Calmic Medical Division The Wellcome Foundation Limited Crewe Hall Crewe, Cheshire CW1 1UB

AEROSPORIN*

Presentation Each rubber-capped vial contains 500,000 i.u. of sterile freeze-dried Polymyxin B Sulphate BP.

Uses Bactericidal antibiotic.

In systemic, urinary tract, meningeal, and local infections caused by a wide range of susceptible Gram-negative organisms, particularly *Pseudomonas aeruginosa*.

Dosage and administration *Intrathecal administration* (for meningitis).

Adults and children over 2 years: 50,000 to a maximum of 100,000 units once daily.

Children under 2 years: 20,000 to a maximum of 40,000 units once daily. Administer the appropriate dosage in 1–2 mls of 0.9% sterile sodium chloride solution.

Treatment should continue daily until the cerebrospinal fluid is sterile and then on alternate days for 1–3 weeks.

If systemic infection is present, concurrent parenteral therapy is required.

Intravenous administration – Adults and children: 15,000–25,000 units per kg. bodyweight per day. Total daily dosage must not exceed 2,000,000 units.

No dosage information is available for intravenous administration in neonates.

The total daily dose may be given as a continuous infusion or as 2 infusions per day each for 1–2 hours and given 12 hours apart. 5% Dextrose in water is recommended as the diluent.

Intramuscular administration – Adults and children: 15,000 to 25,000 units per kg bodyweight per day. Total daily dosage must not exceed 2,000,000 units.

Neonates: 15,000–45,000 units per kg bodyweight per day.

The total daily dose should be given in 4 equally divided doses at 6-hourly intervals. 1–2 mls of water for injection, 0.9% sterile sodium chloride or 1% sterile procaine hydrochloride solution should be used as diluent.

Dosage in renal failure:

<i>Creatinine clearance</i>	<i>Dosage (units/kg/day)</i>
Normal or 80% of normal	25,000
80% to 30% of normal	1st day: 25,000 Daily thereafter 10,000–15,000
25% of normal	1st day: 25,000 Every 2–3 days thereafter 10,000–15,000
Anuria	1st day: 25,000 Every 5–7 days thereafter 10,000

Patients with impaired renal function excrete the drug more slowly and an appropriate adjustment in the intravenous or intramuscular dosage should be made. The table above gives guidelines based on creatinine clearance. Additional guidance should be obtained by regular monitoring of serum levels of polymyxin B and renal function. The serum level of polymyxin B should be kept below 10 µg/ml.

Local administration: A solution of 0.1–1% (approximately 10,000–100,000 units/ml) in sterile saline or an ointment or cream of similar strength is recommended. When used as a solution it may be applied either as drops, as a wet dressing, as a spray, by irrigation or as an aerosol.

Inhalation of an aerosol containing Aerosporin is particularly valuable in treating pulmonary infections due to *Ps. aeruginosa*, *E. coli* and *H. influenzae*. Inhalation of 1–2 ml of solution of 1,000–10,000 i.u. per ml in sterile saline or 5% dextrose in water four to eight times daily is recommended. The total amount given per day should not be more than that used parenterally.

For the treatment of superficial eye infections Aerosporin may be applied in the form of eye drops or by subconjunctival injection:

Eye drops: 3 drops of a 0.1% solution in sterile water or 0.9% sodium chloride solution should be instilled hourly, then less frequently depending on the response.

Subconjunctival injection: Up to 100,000 units per day is recommended, administered in water for injection or sterile 0.9% sodium chloride solution. A concentration of 500,000 units per ml is suggested and not more than 1 ml of diluent should be administered per injection.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to polymyxins.

Precautions: Nephropathy and neuropathy may result from the use of this drug. It may therefore be advisable to monitor renal function before and during parenteral therapy.

The concomitant use of other potentially nephrotoxic drugs should be avoided if possible.

Due to the possibility of neuromuscular blockade leading to respiratory paralysis and apnoea, caution is advised in the administration of other agents with a similar action (eg muscle relaxants, general anaesthetics, antibiotics with muscle relaxant properties).

Side- and adverse effects: Occasionally mild drug fever and a variety of skin eruptions, including urticaria, have been reported after parenteral therapy. Allergic reactions after topical application are rare.

Local pain at the injection site may occur when the drug is given intramuscularly. Subconjunctival injection may also be painful. Intrathecal injection may cause meningeal irritation, particularly in daily doses above 50,000 units and the patient should be observed for reactions.

Polymyxin B may cause nephrotoxicity. This effect is

dose-related and rarely a serious clinical problem in patients with adequate renal function receiving recommended doses; it is usually reversible on discontinuation of the drug.

Neurological symptoms of varying intensity may occur. There may be circumoral and peripheral paraesthesia, some dizziness and a feeling of weakness without, however, any objective signs. These effects are transient and disappear within 48 hours of stopping treatment.

Use in pregnancy and lactation: The safety of Aerosporin in pregnancy has not been established. No information is available on its excretion in breast milk.

Toxicity and treatment of overdose: Antihistamines may relieve some of the subjective symptoms. If respiratory paralysis occurs, artificial respiration should be instituted. There is some evidence that haemodialysis lowers serum levels of the drug. However, the value of this procedure is open to doubt due to tissue localisation of the antibiotic.

Pharmaceutical precautions Store in a dry place, below 25°C. Protect from light. Use immediately after reconstitution.

Legal category POM.

Package quantities Rubber-capped vial of 500,000 i.u.

Further information It is desirable to continue therapy until the lesions are healed; otherwise infecting organisms may reappear if the antibiotic is withdrawn too soon.

In the strengths recommended, Aerosporin is not irritating to delicate tissues such as the eye, mucous membranes or granulating surfaces.

Product licence number 0003/5006.

ANECTINE* INJECTION

Presentation Solution of Suxamethonium Chloride BP 100 mg in 2 ml.

Uses Short-acting depolarising neuromuscular blocking agent for producing muscular relaxation during anaesthesia.

Dosage and administration *Adults:* In most cases an intravenous dose of 60–100 mg will paralyse for about three to five minutes. For continuous drip administration, solutions of 0.1–0.2% of suxamethonium chloride have been employed. Tachyphylaxis may occur after approximately one hour. After a full relaxing dose for intubation the effects have been maintained by infusions of 2.5–4 mg per minute.

Children: Proportionate reduction according to weight. Neonates and premature infants may be relatively resistant to Anectine and develop phase II block more readily.

Contra-indications, warnings, etc

Contra-indications: Since Anectine may cause a rise in intra-ocular pressure it is contra-indicated in patients with glaucoma, detached retina or open eye injury.

Anectine injection is followed by a rise in serum potassium concentration, which may be important in patients with pre-existing hyperkalaemia, for instance, due to renal impairment. The hyperkalaemic response may be excessive, and possibly lead to cardiac arrest in patients with a history of severe burns or trauma several

weeks previously and in patients with an upper or lower motor neurone lesion of a nerve supplying a large muscle mass, spinal cord injuries, tetanus, congenital cerebral palsy and pseudo-hypertrophic muscular dystrophy. Anectine is generally contra-indicated in these patients.

Precautions: Since Anectine causes paralysis of the respiratory muscles it should only be used in the presence of an experienced anaesthetist and when resuscitative equipment is immediately available.

In normal patients Anectine is rapidly hydrolysed by serum cholinesterase. Its action may therefore be prolonged in patients with conditions leading to a reduction in this enzyme, and in individuals with a congenital absence or deficiency of cholinesterase. In such cases respiration must be artificially supported or maintained until it has returned spontaneously and fully.

Anectine should be used with caution, if at all, in the presence of certain major neurological and muscular disorders such as myotonia dystrophica, muscular dystrophy and the myasthenic syndrome. Its action is prolonged by neostigmine, procaine, lignocaine, procainamide, propanidid, quinidine, promazine, diethyl ether, tacrine and hexafluorenum. Its action is opposed by d-tubocurarine, gallamine, cyclopropane, halothane and trifluoperazine.

Side- and adverse effects: Anaphylaxis and bronchospasm have been reported following Anectine.

Anectine may cause bradycardia and, more rarely, tachycardia and increased blood pressure. It is recommended that atropine is given as a premedication prior to the administration of Anectine.

Post-operative muscular pains may occur, particularly in ambulant patients. Some anaesthetists employ small doses of a non-depolarising relaxant prior to administering Anectine as it is believed this will reduce the possibility of muscular pain.

Malignant hyperthermia has followed the use of Anectine in susceptible patients.

Use in pregnancy and lactation: Anectine is generally considered safe in obstetrics although some infants may show decreased respiration and tonus. Anectine is poorly absorbed orally and is unlikely to present a problem in breast-fed infants.

Toxicity and treatment of overdose: The main problem is likely to be prolonged apnoea. Institute general support of respiration until spontaneous recovery.

Pharmaceutical precautions Anectine is rapidly destroyed by alkalis. Although it can be mixed with thiopentone sodium solutions immediately before injections, this is inadvisable because suxamethonium may act before thiopentone. Store below 4°C. Protect from light. Do not freeze.

Legal category POM.

Package quantities Box of 5 × 2 ml ampoules.

Further information Nil.

Product licence number 0003/5203.

CALPOL* SUSPENSION

Presentation Each 5 ml dose contains 120 mg Paracetamol BP in a pleasantly-flavoured pink suspension.

Uses For the relief of pain (including teething pain) and feverishness.

Dosage and administration *Children 3–12 months:* 5 ml four times daily.

1 year to under 6 years: 10 ml four times daily.

6 years to under 12 years: 20 ml four times daily.

Not more than 4 doses should be administered in any 24-hour period; do not repeat doses more frequently than 4-hourly. Dosage for children under 3 months is at physician's discretion.

Contra-indications, warnings, etc

Contra-indications: None known.

Precautions: To be used with caution in the presence of renal or hepatic dysfunction.

Side- and adverse effects: Side-effects with Calpol are rare in therapeutic doses. Paracetamol has been widely used and reports of adverse reactions are rare and are generally associated with overdosage. Isolated cases of thrombocytopenic purpura, methaemoglobinaemia and agranulocytosis have been recorded. Nephrotoxic effects are uncommon and have not been reported in association with therapeutic doses except after prolonged administration. Overdosage may cause hepatic necrosis.

Use in pregnancy and lactation: There is epidemiological evidence of safety with paracetamol in human pregnancy. Paracetamol is excreted in breast milk but not in clinically significant quantities.

Toxicity and treatment of overdosage: Even in severe cases, initial symptoms are likely to be mild and may comprise pallor, nausea and vomiting. Liver damage may not become apparent until 24 hours to 6 days after ingestion.

Overdosage should therefore be treated promptly by gastric lavage followed by i.v., N-acetylcysteine or oral methionine. Additional therapy (further methionine, i.v. N-acetylcysteine or i.v. cysteamine) is normally considered in the light of blood paracetamol content and the time elapsed since ingestion. Such therapy is probably best undertaken in a specialised unit.

Pharmaceutical precautions Store below 25°C. Protect from light.

Legal category P.

Package quantities Bottles of 70 ml, 140 ml and 1 litre.

Further information Nil.

Product licence number 0003/5067.

CICATRIN* AEROSOL

Presentation Each gram contains:

Neomycin Sulphate BP	16,500 units
Zinc Bacitracin BP	1,250 units
L-Cysteine	12 mg
Glycine	60 mg

Uses Topical broad-spectrum antibacterial.

Superficial bacterial infections of skin.

Dosage and administration *Adults:* A thin, uniform spray should be applied to affected areas, as required. This can be obtained from a spray of about one second's duration to the wound surface at a distance of not less than 20 cm. The application of one can of spray daily for a maximum period of 10–12 weeks should not be exceeded in adults. After such a course, treatment should not be repeated for at least three months.

Children: The maximum dosage should be reduced in proportion to body weight.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to bacitracin or the neomycin group of antibiotics.

Precautions: The following statements take into account the possibility that the constituent drugs of Cicatrin Aerosol, particularly neomycin, may be absorbed to a significant degree after topical application.

Ototoxicity and nephrotoxicity have been reported in association with large or prolonged doses of neomycin and nephrotoxicity has also been reported with inappropriate dosing with bacitracin. While these effects are normally reversible on cessation of therapy, the ototoxic effect of neomycin is not.

In cases where there is established partial nerve deafness and where a significant degree of neomycin absorption could occur it might be inappropriate to use any neomycin-containing product and treatment with an antibacterial without an aminoglycoside constituent should be used if possible. In renal impairment the plasma clearance of neomycin is reduced, therefore a reduction in dose should be made that relates to the degree of renal impairment.

The inappropriate use of topical antibiotics has been associated with the emergence of resistant strains of bacteria.

The spray should not be used on large denuded areas (e.g. burns or ulcers) because of the risk of systemic absorption.

Concurrent administration of other aminoglycoside antibiotics is not recommended.

As neomycin has a neuromuscular blocking effect, patients concurrently receiving other agents with a similar action should be observed for signs of possible respiratory insufficiency.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of zinc bacitracin are rare events.

Use in pregnancy: Due to a lack of detailed information, the use of Cicatrin during pregnancy cannot be recommended in circumstances where significant systemic absorption of the active ingredients may occur.

Toxicity and treatment of overdosage: In the event of signs of toxicity developing following significant systemic absorption of the active ingredients of Cicatrin aerosol the patient's general status, hearing acuity and renal function should be monitored and blood levels of neomycin and zinc bacitracin determined. Serum levels of neomycin can be reduced by haemodialysis.

Pharmaceutical precautions Store below 25°C. Keep away from heat. Do not puncture or incinerate.

Legal category POM.

Package quantities Aerosol pack. Net content of powder 3 g approx.

Further information Nil.

Product licence number 0003/5083

**CICATRIN* POWDER
CICATRIN* CREAM**

Presentation Each gram of powder/cream contains:

Neomycin Sulphate BP 3,300 units

Zinc Bacitracin BP	250 units
L-Cysteine	2 mg
Glycine	10 mg
dl-Threonine	1 mg

Uses Topical broad-spectrum antibacterial.

Superficial bacterial infection of skin, such as impetigo, varicose ulcers, pressure sores, trophic ulcers and burns.

Dosage and administration *Adults:* A light dusting of the powder or thin layer of the cream should be applied to the affected skin area up to three times daily. See Contra-indications, warnings, etc.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to bacitracin or the neomycin group of antibiotics.

Precautions: The following statements take into account the possibility that the constituent drugs of Cicatrin Powder/Cream, particularly neomycin, may be absorbed to a significant degree after topical application.

Ototoxicity and nephrotoxicity have been reported in association with large or prolonged doses of neomycin and nephrotoxicity has also been reported with inappropriate dosing with bacitracin. While these effects are normally reversible on cessation of therapy the ototoxic effect of neomycin is not. In consequence, the application of two 30 g tubes of the cream daily for three weeks, or one 50 g puffer pack of the powder daily for four weeks should not be exceeded in adults. After such a course, treatment should not be repeated for at least three months. In children this maximum dosage should be reduced in proportion to body weight.

In renal impairment the plasma clearance of neomycin is reduced, therefore a reduction in dose should be made that relates to the degree of renal impairment.

In cases where there is established partial nerve deafness and where a significant degree of neomycin absorption could occur it might be inappropriate to use any neomycin-containing product and treatment with an antibacterial without an aminoglycoside constituent should be used if possible.

Concurrent administration of other aminoglycoside antibiotics is not recommended.

As neomycin has a neuromuscular blocking effect, patients concurrently receiving other agents with a similar action should be observed for signs of possible respiratory insufficiency.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of zinc bacitracin are rare events.

Use in pregnancy: Due to a lack of detailed information, the use of Cicatrin during pregnancy cannot be recommended in circumstances where significant systemic absorption of the active ingredients may occur.

Toxicity and treatment of overdose: In the event of signs of toxicity developing following significant systemic absorption of the active ingredients of Cicatrin Powder/Cream the patient's general status, hearing acuity and renal function should be monitored and blood levels of neomycin and zinc bacitracin determined. Serum levels of neomycin can be reduced by haemodialysis.

Pharmaceutical precautions Store below 25°C. Keep dry.

Legal category POM.

Package quantities *Cicatrin Powder:* Puffer packs of 15 g and 50 g.

Cicatrin Cream: Tubes of 15 g and 30 g.

Further information Nil.

Cream 0003/5082.

COPARVAX* ▼

Presentation Each vial contains 7 mg (dry weight on the *Corynebacterium parvum* organisms (inactivated) WFL strain CH 6134) in a freeze-dried form. Thiomersal and glycine are added to concentrations of 0.01% and 2.3% prior to freeze-drying.

Uses Coparvax is indicated for the alleviation of malignant pleural effusions and malignant ascites.

Dosage and administration The recommended dose is 7–14 mg, although some patients have responded to lower doses.

Freeze-dried Coparvax should be reconstituted with 1 ml of physiological saline for injection and diluted in a further volume of 10–20 ml prior to injection into the pleural or peritoneal cavity.

Coparvax is injected into the pleural or peritoneal cavity via the paracentesis needle immediately after the effusion has been aspirated. Instillation of Coparvax may be repeated, if necessary, at intervals of one to four weeks.

The suspension should be administered within 24 hours of reconstitution.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Precautions: The incidence and severity of side-effects attributable to Coparvax administered intrapleurally appears to be intensified if given within 10 days of thoracotomy and lung resection probably due to enhanced systemic absorption of Coparvax. It should not be given during the immediate post-operative period.

Following intrapleural or intra-abdominal administration, leakage of Coparvax into subcutaneous tissues may result in local tenderness. Intense fibrinous reaction in the pleural and peritoneal cavities has been observed following local administration of Coparvax. Intestinal obstruction due to the formation of adhesions is a theoretical possibility, although it has not been reported as a complication of Coparvax administration.

Side- and adverse effects: Fever occurs in 10 to 40% of patients following intracavitary injection of Coparvax.

Abdominal pain or mild abdominal discomfort has been reported in some 20% of patients following intraperitoneal injection of Coparvax. Nausea and vomiting may occur in a minority of patients following intracavitary administration of Coparvax.

Use in pregnancy: Since there is no laboratory or clinical data on mutagenicity of teratogenicity, Coparvax should not be administered during pregnancy.

Pharmaceutical precautions Store between 2 and 8°C. Do not freeze.

Legal category POM.

Package quantities Single vials of 7 mg.

Further information Nil.

Product licence number 0003/0097.

CYCLIMORPH* 10 INJECTION CYCLIMORPH* 15 INJECTION

Presentation Cyclimorph 10 Injection contains morphine tartrate 10 mg, cyclizine tartrate 50 mg, in 1 ml.

Cyclimorph 15 Injection contains morphine tartrate 15 mg, cyclizine tartrate 50 mg, in 1 ml.

Uses Cyclimorph Injection is indicated in all medical and surgical conditions where cyclizine is needed in addition to morphine. Cyclimorph contains cyclizine, a non-phenothiazine anti-emetic, which minimises the nausea and vomiting which may be caused by the narcotic. It is particularly useful in the management of myocardial infarction where control of nausea and vomiting is also clearly desirable. Cyclimorph can also be used for the relief of severe pain; left ventricular failure, pulmonary oedema, shock, and post-operative sedation.

Dosage and administration *Adults and children over 12 years:* Usual adult dose – 10–20 mg morphine tartrate subcutaneously, intramuscularly or intravenously.

Children 6–12 years: 5–10 mg morphine tartrate as a maximum single dose.

1–5 years: 2.5–5 mg morphine tartrate as a maximum single dose.

If required, repeat not more often than 4-hourly with not more than 3 doses (representing 150 mg cyclizine tartrate) in any 24-hour period.

Contra-indications, warnings, etc

Contra-indications: Respiratory depression; obstructive airways disease. Concurrent administration with monoamine oxidase inhibitors or within 2 weeks of their discontinuation.

Precautions: Use reduced dosage in the elderly, in hypothyroidism and chronic hepatic disease. Administration during labour may cause respiratory depression in the new-born infant.

Side- and adverse effects: Tolerance and dependence may occur. Drowsiness, dry mouth and blurred vision may occur in a small number of patients, due to the cyclizine component.

Use in pregnancy and lactation:

Morphine: There is inadequate evidence of safety in human pregnancy but the drug has been widely used for many years without apparent ill consequence and animal studies have not shown any hazard. No data available on its excretion in breast milk.

Cyclizine: There is some clinical evidence of safety in human pregnancy. No data available on its excretion in breast milk.

Toxicity and treatment of overdose: These are likely to consist of respiratory depression, hypotension, with circulatory failure and deepening coma.

Naloxone, given intravenously, intramuscularly or subcutaneously, effectively antagonises the toxic effects of morphine. The circulation should be maintained with infusions of dextrose and suitable electrolyte solutions. Assisted respiration may be required.

Note: The use of the specific antidote in addicts tolerant to morphine may produce withdrawal symptoms.

Pharmaceutical precautions Store below 25°C, protect from light.

Legal category POM, MDA.

Package quantities *Cyclimorph 10 Injection;* 1 ml ampoules: Box of 5.

Cyclimorph 15 Injection; 1 ml ampoules: Box of 5.

Further information Nil.

Cyclimorph 15 0003/5023.

DICONAL* TABLETS

Presentation Each tablet contains 10 mg of Dipiprone Hydrochloride BP and 30 mg of Cyclizine Hydrochloride BP, coloured deep pink, scored and coded 'Wellcome F3A'.

Uses Analgesic with anti-emetic action.

Indicated in those medical and surgical conditions where morphine would normally be used. It also contains cyclizine, an anti-emetic which effectively overcomes the nausea and vomiting which may be caused by the narcotic. Often effective in patients who have ceased to respond to morphine or pethidine.

Dosage and administration *Adults:* In all cases an initial dose of 1 tablet should not be exceeded. The onset of action is within an hour and adequate relief from a single dose will last about six hours. The dose can be repeated every six hours if necessary. Should the initial dose prove inadequate, as in cases of severe intractable pain or where other potent analgesics have been used previously, the dose may be increased subsequently by $\frac{1}{2}$ tablet increments. It will seldom be necessary to exceed a dose of 3 tablets.

Children: Not applicable.

Contra-indications, warnings, etc

Contra-indications: Respiratory depression, obstructive airways disease. Concurrent administration with monoamine oxidase inhibitors or within 2 weeks of their discontinuation.

Precautions: Use with caution in patients with severe liver or kidney diseases.

As with all potent analgesics the possibility of addiction cannot be excluded and the usual precautions should be observed.

As with morphine-type drugs respiratory depression is a hazard. Particular care should therefore be taken when increasing the dosage and when treating patients with impaired respiration. Concurrent administration with other CNS depressants including alcohol may enhance the central effects of Diconal.

Side- and adverse effects: Cyclizine may cause drowsiness, dryness of the mouth and blurred vision in a small number of patients.

Use in pregnancy and lactation: No data are available on the use of Diconal in human pregnancy nor of the excretion of it or its metabolites in human milk. Its administration to pregnant or lactating mothers is best avoided unless there are compelling reasons for its use.

Toxicity and treatment of overdose: The main problem with overdose is likely to be respiratory depression. Depressed respiration can be counteracted by the administration of naloxone. Gastric lavage. Oxygen and respiratory support if necessary.

Pharmaceutical precautions Store below 25°C. Protect from light. Keep dry.

Legal category POM, MDA.

Package quantities Bottle of 100 tablets.

Further information Nil.

Product licence number 0003/5027.

DRAPOLENE* CREAM

Presentation Benzalkonium chloride 0.01%, cetrimide 0.2%, in a pink, water-miscible, cream base.

Uses Prevention and treatment of urinary ammonia dermatitis, particularly nappy rash, treatment of minor burns and wounds.

Dosage and administration *Adults:* To be applied twice daily.

Children: To be applied evenly at each nappy change, particular attention being paid to the folds of the skin.

Before applying Drapolene, the affected area should be dry and free from all traces of soap.

Contra-indications, warnings, etc

Contra-indications: Patients with a hypersensitivity to either of the constituents.

Side- and adverse effects: Allergic reactions to Drapolene are rare.

Toxicity and treatment of overdosage: Not applicable.

Pharmaceutical precautions Store below 25°C.

Legal category GSL.

Package quantities Tubes of 55 g and 100 g. Jar of 500 g.

Further information Nil.

Product licence number 0003/5069.

ESBATAL* TABLETS

Presentation

1. Esbatal Tablets containing 10 mg Bethanidine Sulphate BP in each tablet. Peach coloured, scored and coded 'Wellcome P3A'.

2. Esbatal Tablets containing 50 mg Bethanidine Sulphate BP in each tablet. Peach coloured, scored and coded 'Wellcome T3A'.

Uses Antihypertensive agent.

Esbatal is an adrenergic neurone blocking agent which acts selectively on peripheral sympathetic nerves.

It is indicated for all grades of hypertension. Because of its speed of action, it is of special value in malignant hypertension, hypertensive crises and hypertensive heart disease.

Adrenergic neurone blockade is apparent within two hours, with peak effect two to four hours later, and usually disappears within 10–12 hours. There may be some cumulative effect where renal function is impaired.

Esbatal has been used successfully in combination with other established antihypertensive agents.

Dosage and administration *Adults:* Blood pressure should be recorded when the patient is standing.

Starting dose – one 10 mg tablet three times daily, after meals. Where necessary the dosage should be

increased by half a tablet three times daily, at intervals, until effective control is obtained. It is seldom necessary to exceed a dosage of 200 mg daily. Diuretics may be given concurrently. For the elderly and patients with a history of a cerebrovascular accident, half the starting dose is recommended.

Where rapid lowering of blood pressure is urgently needed, an initial dose of 20 mg should be increased by 10–20 mg every four to six hours until control is achieved.

Children: Consult manufacturer.

Contra-indications, warnings, etc

Contra-indications: Patients become very sensitive to any circulating sympathomimetic agent after adrenergic neurone blockade. Hence Esbatal is contra-indicated for patients with phaeochromocytoma. Adrenaline, amphetamine or any other sympathomimetic such as, for example, appetite suppressants, should not be used in patients on Esbatal except on the very rare occasion that its action requires antagonising.

Precautions: Special care should be taken when treating hypertension in patients with disease of cerebral or coronary vasculature or with severe renal damage. As Esbatal is excreted mainly by the kidneys, reduced doses may suffice in renal impairment.

Tricyclic antidepressants antagonise the activity of Esbatal thus necessitating larger doses. If simultaneously prescribed tricyclic antidepressants are discontinued, a substantial reduction in Esbatal requirements must be anticipated.

Side- and adverse effects: The beneficial effects of Esbatal derive from reduced peripheral vascular resistance and are most marked in the erect posture. Transient symptoms of a further reduction in resistance such as faintness, sweating, muscle fatigue and headache may occur with sudden changes in posture, excessive exercise and extremes of temperature, all of which should be avoided. Regularly repeated symptoms can be managed by reducing the size of the dose preceding their onset or by taking the dose after a meal. Sometimes Esbatal disturbs the normal ejaculation of semen. After omission of one or two doses normal sexual function returns. Nasal stuffiness and disturbed micturition may occur. It rarely causes diarrhoea.

Use in pregnancy and lactation: Esbatal has been used to treat hypertension during pregnancy with no apparent untoward effect. There are no data on its use in lactating mothers.

Toxicity and treatment of overdosage: The main problem with overdosage would be severe hypotension. Treatment of overdosage is by means of general supportive measures with intravenous injection of plasma. *Slow* intravenous injection of noradrenaline or phenylephrine may be given under expert supervision.

Pharmaceutical precautions Store below 25°C in a dry place.

Legal category POM.

Package quantities *Tablets 10 mg:* Bottles of 100 and 500 tablets.

Tablets 50 mg: Bottle of 100 tablets.

Further information Nil.

FERROMYN* TABLETS FERROMYN* ELIXIR

Presentation Ferromyn Tablets each contain 100 mg of Ferrous Succinate BP (equivalent to 35 mg elemental iron). Orange coloured.

Ferromyn Elixir: each 5 ml contains 106 mg Ferrous succinate BP (equivalent to 37 mg elemental iron). Brown coloured.

Uses For the prevention and treatment of iron-deficiency anaemias.

Dosage and administration *Adults:* 1 tablet three times a day or 5 ml elixir three times a day.

Children: Ferromyn Elixir.

Up to 2 years: Up to 1 ml twice daily.

2-5 years: 2.5 ml three times daily.

5-10 years: 5 ml twice daily.

Over 10 years: As for adults.

Ferromyn Elixir may be diluted with Syrup BP.

Contra-indications, warnings, etc

Contra-indications: No special comments.

Precautions: May be less well absorbed if taken with food. Iron absorption may be impaired by magnesium trisilicate and carbonates.

If Ferromyn and oral tetracycline are given concomitantly, absorption and therefore serum levels of the antibiotic will be reduced. As with other conventional iron preparations, Ferromyn should not be given within 2 to 3 hours of an oral dose of tetracycline.

Side- and adverse effects: Rarely, gastrointestinal upset may occur.

Use in pregnancy and lactation: As pregnancy is frequently an indication for iron therapy there is no reason to expect problems with Ferromyn therapy. Iron is excreted in breast milk but not in clinically significant amounts (about 0.5 mg/day).

Toxicity and treatment of overdose: The initial symptoms of acute overdose with iron are acute gastric disturbance with epigastric pain, nausea, vomiting and diarrhoea. Haematemesis may occur. These features may be followed by profound cardiovascular collapse and acute encephalopathy.

If serum iron levels exceed 5 mg/l within six hours of dosing, then treatment is a matter of urgency.

Lavage should be carried out using a solution of desferrioxamine (2 g/l of warm water) and 5 g of lesferrioxamine (in 50 to 100 ml water) should be left in the stomach. In addition, 1 g should be given twice daily by intramuscular injection. The antidote may be administered by continuous infusion (15 mg/kg/hr) but blood pressure should be monitored to avoid desferrioxamine hypotension.

It is important to maintain an adequate urine flow.

Pharmaceutical precautions *Tablets:* Store below 15°C.

Elixir: Store below 25°C. Protect from light.

Legal category P.

Package quantities *Ferromyn Tablets:* Plastic container of 100 tablets.

Ferromyn Elixir: Bottle of 100 ml.

Further information Nil.

FERROMYN* 'B' TABLETS FERROMYN* 'B' ELIXIR

Presentation Ferromyn 'B' Tablets each contain 106 mg Ferrous Succinate BP (equivalent to 37 mg elemental iron), Thiamine Hydrochloride BP 1 mg, Riboflavin BP 1 mg, Nicotinamide BP 10 mg. Chocolate brown coloured.

Ferromyn 'B' Elixir. Each 5 ml contains 106 mg Ferrous Succinate BP (equivalent to 37 mg elemental iron), Thiamine Hydrochloride BP 1 mg, Riboflavin BP 1 mg, Nicotinamide BP 10 mg. Dark brown coloured.

Uses For the prevention and treatment of iron-deficiency anaemias accompanied by vitamin B deficiency.

Dosage and administration *Adults:* 1 tablet or 5 ml elixir three times a day, between meals.

Children: Ferromyn 'B' Elixir.

Up to 2 years: Up to 1 ml twice daily.

2-5 years: 2.5 ml three times daily.

5-10 years: 5 ml twice daily.

Over 10 years: As for adults.

Ferromyn 'B' Elixir may be diluted with Syrup BP.

Contra-indications, warnings, etc

Contra-indications: No special comments.

Precautions: May be less well absorbed if taken with food. Iron absorption may be impaired by magnesium trisilicate and carbonates.

If Ferromyn 'B' and oral tetracycline are given concomitantly, absorption and therefore serum levels of the antibiotic will be reduced. As with other conventional iron preparations, Ferromyn 'B' should not be given within 2 to 3 hours of an oral dose of tetracycline.

Side- and adverse effects: Rarely gastrointestinal upset may occur.

Use in pregnancy and lactation: As pregnancy is frequently an indication for iron therapy there is no reason to expect problems with Ferromyn 'B' therapy. Iron is excreted in breast milk but not in clinically significant amounts (about 0.5 mg/day).

Toxicity and treatment of overdose: The initial symptoms of acute overdose with iron are acute gastric disturbance with epigastric pain, nausea, vomiting and diarrhoea. Haematemesis may occur. These features may be followed by profound cardiovascular collapse and acute encephalopathy.

If the serum iron levels exceed 5 mg/l within six hours of dosing, then treatment is a matter of urgency.

Lavage should be carried out using a solution of desferrioxamine (2 g/l of warm water) and 5 g of desferrioxamine (in 50 to 100 ml water) should be left in the stomach. In addition, 1 g should be given twice daily by intramuscular injection. The antidote may be administered by continuous infusion (15 mg/kg/hr) but blood pressure should be monitored to avoid desferrioxamine hypotension.

It is important to maintain an adequate urine flow.

FERROMYN* 'S' TABLETS

Presentation Ferromyn 'S' Tablets each contain 106 mg Ferrous Succinate BP (equivalent to 37 mg elemental iron) and succinic acid 110 mg. Orange coloured.

Uses For the prevention and treatment of iron-deficiency anaemias.

Dosage and administration *Adults:* 1 tablet three times a day.

Children: Not applicable.

Contra-indications, warnings, etc

Contra-indications: No special comments.

Precautions: May be less well absorbed if taken with food. Iron absorption may be impaired by magnesium trisilicate and carbonates.

If Ferromyn 'S' and oral tetracycline are given concomitantly, absorption and therefore serum levels of the antibiotic may be reduced. As with other conventional iron preparations, Ferromyn 'S' should not be given within 2 to 3 hours of an oral dose of tetracycline.

Side- and adverse effects: Rarely, gastrointestinal upset may occur.

Use in pregnancy and lactation: As pregnancy is frequently an indication for iron therapy there is no reason to expect any problems with Ferromyn 'S' therapy. Iron is excreted in breast milk, but not in clinically significant amounts (about 0.5 mg/day).

Toxicity and treatment of overdosage: The initial symptoms of acute overdosage with iron are acute gastric disturbance with epigastric pain, nausea, vomiting and diarrhoea. Haematemesis may occur. These features may be followed by profound cardiovascular collapse and acute encephalopathy.

If the serum iron levels exceed 5 mg/l within six hours of dosing, then treatment is a matter of urgency.

Lavage should be carried out using a solution of desferrioxamine (2 g/l of warm water) and 5 g of desferrioxamine (in 50 to 100 ml water) should be left in the stomach. In addition, 1 g should be given twice daily by intramuscular injection. The antidote may be administered by continuous infusion (15 mg/kg/hr) but blood pressure should be monitored to avoid desferrioxamine hypotension.

It is important to maintain an adequate urine flow.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Container of 100 tablets.

Further information Succinic acid is an iron absorption promoter.

Product licence number 0003/5084.

FERROMYN* 'S' FOLIC TABLETS

Presentation Ferromyn 'S' Folic Tablets each contain 106 mg Ferrous Succinate BP (equivalent to 37 mg elemental iron), succinic acid 110 mg and Folic Acid BP 100 mcg. Cerise coloured.

Uses For the prevention and treatment of combined iron and folic acid deficiency states, such as occur in pregnancy.

Dosage and administration *Adults:* 1 tablet three times a day.

Children: Not applicable.

Contra-indications, warnings, etc

Contra-indications: No special comments.

Precautions: May be less well absorbed if taken with food. Iron absorption may be impaired by magnesium trisilicate and carbonates.

If Ferromyn 'S' Folic and oral tetracycline are given concomitantly, absorption and therefore serum levels of the antibiotic will be reduced. As with other conventional iron preparations, Ferromyn 'S' Folic should not be given within 2 to 3 hours of an oral dose of tetracycline.

Side- and adverse effects: Rarely, gastrointestinal upset may occur.

Use in pregnancy and lactation: Since pregnancy is frequently an indication for iron and folic acid therapy there is no reason to expect any problems with Ferromyn 'S' Folic therapy. Iron is excreted in breast milk but not in clinically significant amounts (about 0.5 mg/day).

Toxicity and treatment of overdosage: The initial symptoms of acute overdosage with iron are acute gastric disturbance with epigastric pain, nausea, vomiting and diarrhoea. Haematemesis may occur. These features may be followed by profound cardiovascular collapse and acute encephalopathy.

If the serum iron levels exceed 5 mg/l within six hours of dosing, then treatment is a matter of urgency.

Lavage should be carried out using a solution of desferrioxamine (2 g/l of warm water) and 5 g of desferrioxamine (in 50 to 100 ml of water) should be left in the stomach. In addition, 1 g should be given twice daily by intramuscular injection. The antidote may be administered by continuous infusion (15 mg/kg/hr) but blood pressure should be monitored to avoid desferrioxamine hypotension.

It is important to maintain an adequate urine flow.

Product licence number 0003/5085.

HYPON* TABLETS

Presentation Each tablet contains:

Acetylsalicylic Acid BP	325 mg
Caffeine BP	10 mg
Codeine Phosphate BP	5 mg

The tablets are yellow and impressed with the word 'HYPON' on one side.

Uses Analgesic and antipyretic.

For symptomatic relief of pain and fever associated with acute and chronic rheumatism, dysmenorrhoea, neuralgia, tonsillitis, influenza, coryza, headaches, and all conditions where an analgesic is indicated.

Dosage and administration *Adults:* 2 tablets every four hours.

Children 6–12 years: 1 tablet every four hours.

A maximum of 12 tablets to be taken in 24 hours.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any of the constituents. Contra-indicated in haemophiliacs and in those with active peptic ulcers.

Precautions: Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term. Aspirin may enhance the effects of oral hypoglycaemics and anticoagulants and inhibit the action of uricosurics. It may precipitate bronchospasm or asthma in susceptible patients. Caution is necessary in renal impairment.

Side- and adverse effects: Occasionally, aspirin may induce hypersensitivity or asthmatic reactions. Gastrointestinal haemorrhages, (occasionally major) have been reported with aspirin. Codeine may sometimes cause constipation.

Use in pregnancy and lactation: No data are available on the use of Hypon in human pregnancy nor on the excretion of it or its metabolites in human milk.

Toxicity and treatment of overdosage: Acute aspirin toxicity would be characterised mainly by vomiting, abdominal pain, tinnitus and hyperventilation. In severe cases, there may be pyrexia and convulsions. Hypoglycaemia and convulsions occur most commonly in children. Respiratory depression from the codeine content may occur.

Treatment comprises gastric aspiration with thorough lavage. Replace fluids and electrolytes as necessary. Forced alkaline diuresis is the treatment of choice for accelerating elimination of absorbed salicylate.

Pharmaceutical precautions Store below 25°C in a dry place.

Legal category P.

Package quantities Strip pack of 12. Drum of 300.

Further information Nil.

Product licence number 0003/0119.

IEOSPORIN* EYE DROPS

Presentation Each ml of the sterile faintly opalescent solution contains:

Polymyxin B Sulphate BP	5,000 units
Neomycin Sulphate BP	1,700 units
Gramicidin USNF	25 units

Also contains Thiomersal BP (0.001%) as preservative.

Uses Topical antibacterial agent.

For the prophylaxis and treatment of external bacterial infections of the eye. Prophylactically, it is useful following removal of foreign bodies, and before and after phthalmic surgery, to help provide and maintain a sterile field.

Dosage and administration *Adults:* 1 or 2 drops in the affected eye, two to four times daily or more frequently as required. In severe infections, therapy

should be started with 1 or 2 drops every 15 to 30 minutes, reducing the frequency of instillation gradually as the infection is controlled.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to polymyxins, gramicidin or the neomycin group of antibiotics.

Precautions: Neomycin is ototoxic and nephrotoxic if absorbed from open surfaces. Polymyxin B and gramicidin are also nephrotoxic. However, these effects are unlikely with ocular administration.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of polymyxin B and gramicidin are rare events.

Toxicity and treatment of overdosage: Not applicable.

Pharmaceutical precautions Store below 15°C. Keep dry. Protect from light.

Not suitable for injection. Discard four weeks after opening.

Legal category POM.

Package quantities Special dropper tube of 5 ml.

Further information Neosporin is a non-irritating isotonic solution and is well tolerated by the sensitive structures of the eye.

Product licence number 0003/5108.

OTOSPORIN* DROPS

Presentation Each ml of aqueous vehicle contains:

Polymyxin B Sulphate BP	10,000 units
Neomycin Sulphate BP	3,400 units
Hydrocortisone BP	10 mg

White in colour.

Uses Topical antibacterial and anti-inflammatory.

In the treatment of bacterial infection and inflammation of the external auditory meatus.

Dosage and administration *Adults:* 3 drops should be instilled into the affected ear three or four times daily. Alternatively, a gauze wick may be introduced into the external auditory canal and kept saturated with the solution; the wick may be left in place for 24 to 48 hours.

Children: As for adults.

The external auditory meatus and canal should be thoroughly cleansed and carefully dried before each application, but soap should not be used as the antibiotics may be inactivated by it.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to polymyxins or the neomycin group of antibiotics.

Precautions: Delayed progressive ototoxicity has been reported in animals following administration of neomycin and polymyxin B to the middle ear. In patients who may have a perforation of the ear drum, it is recommended that the dosage should be restricted to a maximum of three drops three times daily for 10 days.

Prolonged use may result in overgrowth of non-susceptible organisms, including fungi.

In infants long-term continuous topical steroid therapy should be avoided. Adrenal suppression can occur, even without occlusion.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of polymyxin B are rare events.

Toxicity and treatment of overdosage: Not applicable.

Pharmaceutical precautions Store below 15°C. Protect from light.

Legal category POM.

Package quantities Bottles of 5 ml and 10 ml.

Further information Nil.

Product licence number 0003/5106.

PARAHYPON* TABLETS

Presentation Each tablet contains:

Paracetamol BP	500 mg
Codeine Phosphate BP	5 mg
Caffeine BP	10 mg

The tablets are pink, scored on one side and impressed with the name 'PARA-HYPON' on the other.

Uses Analgesic.

For the relief of pain associated with arthritis, rheumatism and other diseases of the skeletal system, headache, toothache, colds and influenza and other conditions where simple analgesia is required.

Dosage and administration *Adults and children over 12 years:* 2 tablets up to four times daily.

Children 6–12 years: 1 tablet up to four times daily.

Not more than 4 doses should be administered in any 24-hour period; do not repeat dose more frequently than 4-hourly.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any of the constituents.

Precautions: Use with caution in the presence of renal or hepatic dysfunction.

Side- and adverse effects: Side-effects with Parahypion are rare in therapeutic doses. Paracetamol has been widely used and reports of adverse reactions are rare, and are generally associated with overdosage. Isolated cases of thrombocytopenic purpura, methaemoglobinemia, and agranulocytosis have been recorded. Nephrotoxic effects are uncommon and have not been reported in association with therapeutic doses, except after prolonged administration.

Codeine may sometimes cause constipation.

Use in pregnancy and lactation: No data are available on the use of Parahypion in human pregnancy nor on the excretion of it or its metabolites in human milk.

Toxicity and treatment of overdosage: Even in severe cases, initial symptoms are likely to be mild and may comprise pallor, nausea and vomiting. Liver damage may not become apparent for 24 hours to 6 days after ingestion.

Overdosage should therefore be treated promptly by gastric lavage followed by i.v. N-Acetylcysteine or oral methionine. Additional therapy (further methionine, i.v. N-Acetylcysteine or i.v. cysteamine) is normally considered in the light of blood paracetamol content and the time elapsed since ingestion. Such therapy is probably best undertaken in a specialised unit.

Pharmaceutical precautions Store below 25°C. Keep dry. Protect from light.

Legal category P.

Package quantities Strip-pack of 12. Container of 100 tablets.

Further information Nil.

Product licence number 0003/0118.

POLYBACTRIN* SOLUBLE GU

Presentation One vial contains, in sterile dry powder

Polymyxin B Sulphate BP	75,000 units
Neomycin Sulphate BP	20,000 units
Bacitracin BP 1968	1,000 units

Uses Antibacterial for bladder irrigation only.

To treat and prevent bacteriuria and prevent Gram-negative rod bacteraemia associated with the use of indwelling catheters. For temporary retention in the bladder following intermittent catheterisation and following cystoscopy.

Dosage and administration Reconstitute in 10 ml of isotonic saline then transfer to the appropriate volume of isotonic saline and mix. *Adults:* For continuous irrigation of the bladder for periods up to 10 days, a three-way catheter should be used. Two vials of powder dissolved in 500 ml of isotonic saline provide for a slow drip to be delivered over 24 hours. For patients with a urine output exceeding 2 litres per day, it is recommended that the drip rate be doubled.

Following intermittent catheterisation or cystoscopy 1 vial of powder dissolved in 10–40 ml of isotonic saline may be introduced into the bladder and retained for an hour. This treatment may be used twice daily. See Contra-indications, warnings, etc.

Children: Proportionate reduction in dose according to weight.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to polymyxins, bacitracin or the neomycin group of antibiotics.

Precautions: The following statements take into account the possibility that the constituent drugs of Polybactrin Soluble GU, particularly neomycin, may be absorbed to a significant degree after topical application. There is some evidence that neomycin diffuses across, particularly the denuded, bladder mucosa, hence such factor should be taken into consideration in the use of Polybactrin Soluble GU.

Ototoxicity and nephrotoxicity have been reported in association with large or prolonged doses of neomycin nephrotoxicity and neurotoxicity with polymyxin B nephrotoxicity with inappropriate dosing of bacitracin. While these effects are normally reversible on cessation of therapy, the ototoxic effect of neomycin is not.

Due to the fact that if neomycin-related ototoxicity occurs there is a delay in onset of its appearance, it would be unwise to give a further course of Polybactrin Soluble GU before three months have elapsed from the prior course, by which time any such effects would be evident on examination.

In renal impairment the plasma clearance of neomycin is reduced, therefore a reduction in dose should be made that relates to the degree of renal impairment.

In cases where there is established partial nerve deafness and where a significant degree of neomycin

bsorption could occur it might be inappropriate to use any neomycin-containing product and treatment with an antibacterial without an aminoglycoside constituent should be used if possible.

Concurrent administration of other aminoglycoside antibiotics is not recommended.

As neomycin has a neuromuscular blocking effect, patients concurrently receiving other agents with a similar action should be observed for signs of possible respiratory insufficiency.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of polymyxin B and bacitracin are rare events.

Use in pregnancy: Due to a lack of detailed information the use of Polybactrin Soluble GU during pregnancy cannot be recommended in circumstances where significant systemic absorption of the active ingredients may occur.

Toxicity and treatment of overdosage: In the event of signs of toxicity developing following significant systemic absorption of the active ingredients of Polybactrin Soluble GU, the patient's general status, hearing acuity, renal function and neuromuscular function should be monitored and blood levels of polymyxin B, neomycin, and bacitracin determined. Serum levels of neomycin can be reduced by haemodialysis.

Pharmaceutical precautions Store below 15°C. Keep dry. Protect from light.

Solutions should be used within 24 hours of their preparation.

Legal category POM.

Package quantities Pack of 5 sterile vials.

Further information Nil.

Product licence number 0003/5055.

'POLYBACTRIN' SPRAY

Presentation A sterile powder. Each 115 ml pressurised canister contains:

Polymyxin B Sulphate BP	150,000 units
Neomycin Sulphate BP	495,000 units
Zinc Bacitracin BP	37,500 units

an aerosol propellant.

Uses Topical antibacterial powder.

Prevention of wound infection in surgery. Treatment of infected skin.

Dosage and administration *Adults:* A thin, uniform spray should be applied to affected areas, as required. This can be obtained from a spray of about one second's duration to the wound surface at a distance of not less than 20 cm. The application of one can of spray daily for even days should not be exceeded. After such a course, treatment should not be repeated for at least three months.

Children: The maximum dosage should be reduced in proportion to body weight.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to polymyxins, bacitracin or the neomycin group of antibiotics.

Precautions: The following statements take into account the possibility that the constituent drugs of Polybactrin

Spray, particularly neomycin, may be absorbed to a significant degree after topical application.

Ototoxicity and nephrotoxicity have been reported in association with large or prolonged doses of neomycin; nephrotoxicity and neurotoxicity with polymyxin B; nephrotoxicity with inappropriate dosing of bacitracin. While these effects are normally reversible on cessation of therapy, the ototoxic effect of neomycin is not.

In cases where there is established partial nerve deafness and where a significant degree of neomycin absorption could occur it might be inappropriate to use any neomycin-containing product and treatment with an antibacterial without an aminoglycoside constituent should be used if possible.

In renal impairment the plasma clearance of neomycin is reduced, therefore a reduction in dose should be made that relates to the degree of renal impairment.

The inappropriate use of topical antibiotics has been associated with the emergence of resistant strains of bacteria.

The spray should not be used on large denuded areas (e.g. burns or ulcers) because of the risk of systemic absorption.

Concurrent administration of other aminoglycoside antibiotics is not recommended.

As neomycin has a neuromuscular blocking effect, patients concurrently receiving other agents with a similar action should be observed for signs of possible respiratory insufficiency.

Side- and adverse effects: Allergic reactions following the topical application of neomycin have been reported in the literature, but such reactions following the application of polymyxin B and bacitracin are rare events.

Use in pregnancy: Due to a lack of detailed information the use of Polybactrin Spray during pregnancy cannot be recommended in circumstances where significant systemic absorption of the active ingredients may occur.

Toxicity and treatment of overdosage: In the event of signs of toxicity developing following significant systemic absorption of the active ingredients of Polybactrin Spray, the patient's general status, hearing acuity, renal function and neuromuscular function should be monitored and blood levels of polymyxin B, neomycin, and bacitracin determined. Serum levels of neomycin can be reduced by haemodialysis.

Pharmaceutical precautions Do not expose to temperatures over 50°C. Do not puncture or incinerate even after use. Do not autoclave.

Legal category POM.

Package quantities Pressurised aerosol powder spray, volume 115 ml.

Further information Nil.

Product licence number 0003/5056.

POLYFAX' OINTMENT

Presentation Polyfax Ointment contains 10,000 units of Polymyxin B Sulphate BP and 500 units of Zinc Bacitracin BP per gram, in a stable petrolatum base. The ointment is pale yellow in colour.

Uses Topical antibacterial agent.

Polyfax Ointment is indicated for the treatment of infected wounds, burns, skin grafts, ulcers, pyoderma, sycosis barbae, impetigo, and in secondarily infected

skin lesions of scabies, pediculosis, tinea pedis and contact and allergic dermatitis.

Dosage and administration *Adults:* Polyfax Ointment should be applied thinly over the affected area, which is best left exposed. Two or more applications a day may be necessary, depending on the severity of the condition.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to bacitracin and polymyxins.

Precautions: The following statements take into account the possibility that the constituent drugs of Polyfax Ointment may be absorbed to a significant degree after topical application.

Nephrotoxicity may result from the absorption of bacitracin, and nephrotoxicity and neurotoxicity from polymyxin B. These effects are normally reversible after cessation of therapy.

In patients with renal impairment the dosage of polymyxin B should be restricted to 10,000 to 15,000 units/kg/day, which is equivalent to about three tubes of Polyfax Ointment each day for an average adult.

Side- and adverse effects: Allergic reactions following topical application of polymyxin B and zinc bacitracin have rarely been reported.

Use in pregnancy: Due to a lack of detailed information, the use of Polyfax Ointment during pregnancy cannot be recommended in circumstances where significant systemic absorption of the active ingredients may occur.

Toxicity and treatment of overdosage: In the unlikely event of significant systemic absorption of the active ingredients of Polyfax Ointment occurring, signs of neurotoxicity and nephrotoxicity may be noted. In such an event, the patient's general status and renal function should be monitored and blood levels of polymyxin B and zinc bacitracin determined.

Pharmaceutical precautions Store below 25°C.

Legal category POM.

Package quantities Tube of 20 g.

Further information Nil.

Product licence number 0003/5230.

POLYFAX* OPHTHALMIC OINTMENT

Presentation Polyfax Ophthalmic Ointment contains 10,000 units of Polymyxin B Sulphate BP and 500 units of Zinc Bacitracin BP per gram, in a stable petrolatum base. The ointment is pale yellow in colour.

Uses Topical antibacterial agent.

Polyfax Ophthalmic Ointment is indicated for the treatment of styes, conjunctivitis, keratitis, corneal ulcers and blepharitis. It may also be used prophylactically after the removal of foreign bodies from the eye, and in pre- and post-operative management.

Dosage and administration *Adults:* Polyfax Ophthalmic Ointment should be applied thinly to the affected area or inside the lower eyelid. Two or more applications a day depending on the severity of the condition.

Children: As for adults.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to bacitracin or polymyxins.

Precautions: Polymyxin B and bacitracin are nephrotoxic if absorbed from open surfaces. However, these effects are unlikely with ocular administration.

Side- and adverse effects: Allergic reactions following topical application of polymyxin B and zinc bacitracin have rarely been reported.

Toxicity and treatment of overdosage: Not applicable.

Pharmaceutical precautions Store below 25°C.

Legal category POM.

Package quantities Tube of 4 g.

Further information Polyfax Ophthalmic Ointment is bland and non-irritating and is well tolerated by the sensitive structures of the eye.

Product licence number 0003/5229.

SUDAFED* TABLETS SUDAFED* ELIXIR

Presentation Each tablet contains 60 mg Pseudoephedrine Hydrochloride BP, and is white in colour and coded 'Wellcome S7A'.

Each 5 ml of deep pink elixir contains 30 mg Pseudoephedrine Hydrochloride BP.

Uses Nasal and sinus decongestant.

Dosage and administration *Adults and children over 12 years:* 1 tablet or 10 ml three times a day.

Children: 6-12 years: 7.5 ml elixir three times a day.

1-6 years: 5 ml elixir three times a day.

3-12 months: 2.5 ml elixir three times a day
Sudafed elixir may be diluted with Syrup BP.

Pharmacology: Pseudoephedrine has direct and indirect sympathomimetic activity and is an orally effective upper respiratory tract decongestant. Pseudoephedrine is substantially less potent than ephedrine in producing both tachycardia and elevation in systolic blood pressure and considerably less potent in causing stimulation of the central nervous system.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in patients who have previously shown intolerance to pseudoephedrine. It is contra-indicated in persons under treatment with monoamine oxidase inhibitors and within two weeks of stopping such treatment.

Precautions: Although pseudoephedrine has virtually no pressor effect in patients with normal blood pressure, Sudafed should be used with caution in patients with cardiovascular disorders, including hypertension. The effect of antihypertensive agents which modify sympathetic activity may be partially reversed by Sudafed.

Caution should also be exercised in patients taking other sympathomimetic agents, such as decongestants, appetite suppressants and amphetamine-like psychostimulants. The effects of a single dose on the blood pressure of these patients should be observed before recommending repeated or unsupervised treatment.

As with other sympathomimetic agents, caution should be exercised in patients with prostatic enlargement or bladder dysfunction.

In severe hepatic or renal dysfunction a single dose of

Sudafed should be given and the patient's response used as a guide to the dosage requirement for further administration.

The antibacterial agent furazolidone is known to cause a progressive inhibition of monoamine oxidase and although there are no reports of hypertensive crises having occurred, it should not be administered concurrently with Sudafed.

Side- and adverse effects: Side-effects are uncommon. In some patients pseudoephedrine may occasionally cause insomnia.

A fixed drug eruption to pseudoephedrine, taking the form of erythematous nummular patches has been reported, but is a rare occurrence.

Use in pregnancy and lactation: No data are available on the use of Sudafed in human pregnancy nor on the excretion of it or its metabolites in human milk.

Toxicity and treatment of overdose: As with other sympathomimetic agents, symptoms of overdose include irritability, convulsions, palpitations, hypertension and difficulty in micturition. Gastric lavage and supportive measures for respiration and circulation should be performed if indicated. Convulsions should be controlled with an anticonvulsant. Catheterisation of the bladder may be necessary. Alpha-adrenergic blockade may be required to treat hypertensive crises and beta-adrenergic blockade for the control of supraventricular dysrhythmias.

Pseudoephedrine has a renal excretion half-life of approximately seven hours and if desired the elimination can be accelerated by acid diuresis or by dialysis.

Pharmaceutical precautions Store below 25°C in a dry place. Elixir should be protected from light.

Legal category P.

Package quantities *Sudafed tablets:* Container of 100 tablets. 12 tablets in blister strips of 6.
Sudafed elixir: Bottles of 100 ml and 1 litre.

Further information Nil.

Tablets 0003/5061.

Elixir 0003/5062.

UDAFED[®]-CO TABLETS

Description White scored tablets coded 'Wellcome 7C' containing 500 mg Paracetamol BP and 60 mg pseudoephedrine Hydrochloride BP.

Uses For the relief of conditions where upper respiratory congestion is associated with pyrexia or pain. These conditions include the common cold, influenza, sinusitis and nasopharyngitis.

Dosage and administration *Adults and children over 2 years:* One tablet three times a day.

Children 6–12 years: Half a tablet three times a day.

Pharmacology: Pseudoephedrine has direct and indirect sympathomimetic activity and is an orally effective upper respiratory tract decongestant. Pseudoephedrine is substantially less potent than ephedrine in producing both tachycardia and elevation in systolic blood pressure and is considerably less potent in causing stimulation of the central nervous system. Paracetamol provides analgesic and antipyretic activity, probably by antagonising cerebral prostaglandin synthetase.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in patients with a known hypersensitivity to paracetamol or pseudoephedrine. It is contra-indicated in persons under treatment with monoamine oxidase inhibitors and within two weeks of stopping such treatment.

Precautions: Although pseudoephedrine has virtually no pressor effect in patients with normal blood pressure, Sudafed-Co should be used with caution in patients with cardiovascular disorders including hypertension. The effect of antihypertensive agents which modify sympathetic activity may be partially reversed by Sudafed-Co.

Also caution should be exercised in patients taking other sympathomimetic agents, such as decongestants, appetite suppressants and amphetamine-like psychostimulants. The effects of a single dose on the blood pressure of these patients should be observed before recommending repeated or unsupervised treatment.

As with other sympathomimetic agents, caution should be exercised in patients with prostatic enlargement or bladder dysfunction.

In severe hepatic or renal dysfunction a single dose of Sudafed-Co should be given and the patient's response used as a guide to the dosage requirement for further administration.

The antibacterial agent furazolidone is known to cause a progressive inhibition of monoamine oxidase and, although there are no reports of a hypertensive crisis having occurred, it should not be administered concurrently with Sudafed-Co.

Side- and adverse effects: Side-effects are uncommon. In some patients pseudoephedrine may occasionally cause insomnia. A fixed drug eruption to pseudoephedrine taking the form of erythematous nummular patches has been reported but is a rare occurrence. Paracetamol has been widely used and reports of adverse reactions are rare, and are generally associated with overdose. Isolated cases of thrombocytopenic purpura, methaemoglobinemia and agranulocytosis have been recorded. Nephrotoxic effects are uncommon and have not been reported in association with therapeutic doses, except after prolonged administration.

Use in pregnancy and lactation: No data are available on the use of Sudafed-Co in human pregnancy or the excretion of it or its metabolites in human milk.

Toxicity and treatment of overdose: Pallor, nausea and vomiting may occur due to the paracetamol component. With pseudoephedrine, symptoms of overdose may include irritability, convulsions, palpitations, hypertension, and difficulty in micturition. Hepatotoxicity may be a complication from the paracetamol content but may not be apparent from 24 hours–6 days after ingestion.

Overdose should, therefore, be treated promptly by gastric lavage followed by i.v. N-acetylcysteine, or oral methionine. Additional therapy (further methionine or i.v. cysteamine or i.v. N-acetylcysteine) is normally considered in the light of blood paracetamol content and the time elapsed since ingestion. Such therapy is probably best undertaken in a specialised unit. Supportive measures for respiration and circulation should be performed if indicated. Convulsions should be controlled with an anticonvulsant. Catheterisation of the bladder may be necessary. Alpha-adrenergic blockade may be required to treat hypertensive crises and beta-adrenergic blockade for the control of supraventricular dysrhythmias. Pseudoephedrine has a renal excretion half-life of approximately seven hours and if desired the elimination can be accelerated by acid diuresis or by dialysis.

Pharmaceutical precautions Store below 25°C in a dry place. Protect from light.

Legal category P.

Package quantities 12 tablets in blister strips of 6.

Further information Nil.

Product licence number 0003/0157.

SUDAFED* EXPECTORANT

Presentation Each 5 ml of orange red syrup contains 100 mg Guaiphenesin BP and 30 mg Pseudoephedrine Hydrochloride BP.

Uses Conditions where an expectorant and upper respiratory tract decongestant are required.

Dosage and administration *Adults and children over 12 years:* 10 ml three times a day.

Children 6–12 years: 5 ml three times a day.

1–6 years: 2.5 ml three times a day.

May be diluted with Syrup BP.

Pharmacology: Pseudoephedrine has direct and indirect sympathomimetic activity and is an orally effective upper respiratory tract decongestant. Pseudoephedrine is substantially less potent than ephedrine in producing both tachycardia and elevation in systolic blood pressure and considerably less potent in causing stimulation of the central nervous system. On the basis of widespread and long established clinical use, guaiphenesin is recognised as an expectorant in bronchitis.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in patients who have previously shown intolerance to pseudoephedrine or guaiphenesin. Sudafed Expectorant is contra-indicated in persons under treatment with monoamine oxidase inhibitors and within two weeks of stopping such treatment.

Precautions: Although pseudoephedrine has virtually no pressor effect in patients with normal blood pressure, Sudafed Expectorant should be used with caution in patients with cardiovascular disorders, including hypertension. The effect of antihypertensive agents, which modify sympathetic activity may be partially reversed by Sudafed Expectorant.

Also caution should be exercised in patients taking other sympathomimetic agents, such as decongestants, appetite suppressants and amphetamine-like psychostimulants. The effects of a single dose of Sudafed Expectorant on the blood pressure of these patients should be observed before recommending repeated or unsupervised treatment.

As with other sympathomimetic agents, caution should be exercised in patients with prostatic enlargement or bladder dysfunction.

In severe hepatic or renal dysfunction a single dose of Sudafed Expectorant should be given and the patient's response used as a guide to the dosage requirement for further administration.

The antibacterial agent furazolidone is known to cause a progressive inhibition of monoamine oxidase and, although there are no reports of hypertensive crises having occurred, it should not be administered concurrently with Sudafed Expectorant.

Side- and adverse effects: Side-effects are uncommon.

In some patients pseudoephedrine may occasionally cause insomnia.

A fixed drug eruption to pseudoephedrine, taking the form of erythematous nummular patches has been reported, but is a rare occurrence.

Use in pregnancy and lactation: No data are available or the use of Sudafed Expectorant in human pregnancy or the excretion of it or its metabolites in human milk.

Toxicity and treatment of overdosage: As with other sympathomimetic agents, symptoms of overdosage include irritability, convulsions, palpitations, hypertensor and difficulty in micturition. Gastric lavage and supportive measures for respiration and circulation should be performed if indicated. Convulsions should be controlled with an anticonvulsant. Catheterisation of the bladder may be necessary.

Alpha-adrenergic blockade may be required to treat hypertensive crises and beta-adrenergic blockade for the control of supraventricular dysrhythmias. Pseudoephedrine has a renal excretion half-life of approximately seven hours and if desired the elimination can be accelerated by acid diuresis or by dialysis.

Pharmaceutical precautions Store below 25°C. Protect from light. Do not refrigerate.

Legal category P.

Package quantities Bottle of 1 litre.

Further information Nil.

Product licence number 0003/0145.

TUBARINE* INJECTION

Presentation Each ampoule contains 15 mg of Tubocurarine Chloride BP in 1.5 ml (Tubocurarine Injection BP).

Uses d-Tubocurarine is a non-depolarising agent used to relax the muscles for surgical, anaesthetic and investigatory procedures, and to facilitate control of respiration.

Dosage and administration *Adults:* Intravenous administration of d-tubocurarine induces a paralysis of skeletal muscles within minutes. The level of consciousness is not affected.

Because there is a wide variation in the response to d-tubocurarine the dosage should be adjusted individually for each patient, and the following doses are intended only as a guide.

A 20 mg dose could be taken as an average for a 70 kg man. The mean recovery time from this dose (to 25% twitch suppression) has been shown to be 26 minutes.

Increments of 5 mg d-tubocurarine have been used to maintain relaxation during surgery in adults.

Children: 1 mg per 3 kg bodyweight is suggested as a guide. Neonates are more sensitive than adults to the neuromuscular blocking effect of d-tubocurarine when given on a mg/kg basis. 250 mcg/kg at birth, increased to 500 mcg/kg at 28 days of age has been recommended as an initial dose, but this should be reduced in cases of prematurity, acidosis and hypothermia. Incremental doses of one-fifth to one-sixth the original dose have been used.

Contra-indications, warnings, etc

Contra-indications: Tubarine is contra-indicated in patients who have a history of allergic or hypersensitive reactions to d-tubocurarine.

Precautions: Like other neuromuscular blocking agents, d-tubocurarine causes paralysis of the respiratory muscles. It should only be used in the presence of an experienced anaesthetist, and when resuscitative equipment is immediately available.

Diminished renal function may prolong the duration of action of d-tubocurarine at high doses.

d-Tubocurarine requirements may be increased in patients with liver damage.

Respiratory acidemia has been found to prolong, and respiratory alkalemia to reduce, the time taken to recover from d-tubocurarine-induced neuromuscular blockade.

Prolonged curarisation following 20 mg d-tubocurarine has been reported in a patient with hypocalcaemia.

Patients with myasthenia gravis have been shown to be, on average, $5\frac{1}{2}$ times more sensitive to d-tubocurarine than non-myasthenic subjects. Increased sensitivity to d-tubocurarine has also been shown in patients with myasthenic syndrome complicating bronchial carcinoma, in carcinomatous neuropathy, amyotrophic lateral sclerosis, von Recklinghausen's disease and Duchenne muscular dystrophy.

Cooling decreases the magnitude of the neuromuscular blockade produced by d-tubocurarine. Thus, in patients after operations under hypothermia, prolonged curarisation could occur on rewarming.

Two cases have been reported in which malignant hyperpyrexia may have been triggered by d-tubocurarine.

The neuromuscular blocking action of d-tubocurarine is reported to be potentiated by:

1. Anaesthetic agents such as halothane, isoflurane, enflurane and methoxyflurane. The interaction is particularly marked in the case of diethyl ether. Generally, the degree of potentiation is related to the alveolar concentrations of these agents.

2. Antibiotics such as neomycin, streptomycin, kanamycin, colistin, polymyxin B, certain tetracyclines, possibly bacitracin, clindamycin, lincomycin and entamicin.

3. Other non-depolarising neuromuscular blocking agents, such as gallamine and pancuronium. d-Tubocurarine and suxamethonium are basically antagonistic, though synergism has occurred.

4. Magnesium sulphate.

5. Propranolol, lignocaine, procainamide, diphenylhydantoin and quinidine.

6. Frusemide and possibly mannitol.

Patients receiving treatment with azathioprine or lymphocyte globulin may require twice the usual dose of d-tubocurarine. The effect of azathioprine is further increased by concomitant administration of methylnalazine.

Side- and adverse effects: Bronchospasm and cardiac arrest following d-tubocurarine administration have been reported in a patient with a minor history of allergic asthma.

d-Tubocurarine frequently causes a fall in mean arterial pressure, peripheral vascular resistance and central venous pressure; and a rise in heart rate. Normally, these changes are slight and transient. The hypotensive effect of d-tubocurarine may be enhanced by halothane.

Use in pregnancy and lactation: A single case has been reported in which arthrogryposis multiplex congenita allowed the use of d-tubocurarine for a 10-day period the 10th–12th week of pregnancy. After administration during obstetric operations, d-tubocurarine can be

detected in the cord serum in very low concentrations, which are unlikely to be of any clinical significance to the foetus.

Tubarine is poorly absorbed orally and is unlikely to present a problem to the breast-fed infant.

Toxicity and treatment of overdosage: The neuromuscular blockade due to d-tubocurarine may be reversed by an anticholinesterase such as neostigmine 2.5–5 mg given intravenously. Atropine (1.2–2.4 mg) should be injected intravenously at the same time or immediately before the neostigmine.

In neonates, one hour after the recommended initial dose, reversal may be obtained with atropine 0.018 mg/kg and neostigmine 0.08 mg/kg given intravenously.

If neuromuscular blockade cannot be adequately reversed by the use of an anticholinesterase, then measures should be taken to maintain respiration and, if necessary, the circulation, until neuromuscular function returns. Sedation may also be required.

Pharmaceutical precautions Store below 25°C. Protect from light.

Legal category POM.

Package quantities Box of 5 × 1.5 ml ampoules.

Further information Nil.

Product licence number 0003/5065.

VALOID* TABLETS VALOID* INJECTION

Presentation Valoid Tablets each contain 50 mg Cyclizine Hydrochloride BP, scored, coded 'Wellcome T4A', white in colour.

Valoid Injection contains 50 mg cyclizine lactate in each 1 ml ampoule.

Uses Anti-emetic. In the prevention and treatment of nausea and vomiting and drug-induced vomiting, especially that associated with the administration of narcotic drugs. It has been widely and effectively used in the prophylaxis and treatment of motion sickness, in the symptomatic management of vertigo and labyrinthine disorders (Meniere's syndrome), in postoperative vomiting and in radiation sickness, particularly when this is associated with the treatment of breast cancer.

Dosage and administration *Valoid Tablets: Adults and children over 10 years:* 1 tablet three times daily.

Children 1–10 years: $\frac{1}{2}$ tablet three times daily.

Valoid Injection: Adults and children over 10 years: 50 mg intramuscularly or intravenously three times daily.

For the prevention of postoperative nausea and vomiting, administer the first dose 15–20 minutes before the anticipated end of surgery.

Contra-indications, warnings, etc

Contra-indications: In the light of present knowledge and uncertainties about possible teratogenic agents, current authoritative opinion is that no drug should be taken by a pregnant woman, especially during the first four months of pregnancy, except under medical supervision.

Precautions: Drowsiness, dryness of the mouth and blurred vision may occur in a small number of patients. It is, therefore, advisable that patients should determine their responses before driving or operating machinery. In

some patients the action of Valoid may be potentiated by alcohol and other central sedatives.

Side- and adverse effects: Intravenous cyclizine may increase the incidence of tremors and muscle movements if given before methohexitone anaesthesia.

Although very rare, anaphylaxis of a severe degree has been reported with the co-administration of intravenous cyclizine and propanidol.

Use in pregnancy and lactation: See contra-indications above. No information is available on the use of cyclizine in lactating mothers.

Toxicity and treatment of overdosage: Toxicity may comprise drowsiness, dizziness, convulsions, hyperpyrexia and respiratory depression. Rarely, agitation, ataxia and hallucinations may occur. Gastric lavage and general supportive measures are indicated. Control any convulsions with diazepam injections.

Pharmaceutical precautions *Injection:* Store below 25°C. Protect from light.

Tablets: Store below 25°C.

Legal category Tablets P.
Injection POM.

Injection 0003/5212.

VASOXINE* INJECTION

Presentation Each 1 ml ampoule contains 20 mg Methoxamine Hydrochloride BP (Methoxamine Injection BP).

Uses Methoxamine is indicated for counteraction of hypotension. The most common clinical application for methoxamine is the correction or prevention of hypotension associated with the use of antihypertensive drugs and spinal anaesthetics.

Methoxamine is indicated when pressor therapy is deemed appropriate during, and as a result of, the administration of cyclopropane or halogenated anaesthetics.

Methoxamine is also indicated for the arrest of supraventricular tachycardia.

Dosage and administration *Adults:* 5–10 mg (0.25–0.5 ml) Vasoxine intravenously at a rate of 1 mg/min.
5–20 mg (0.25–1.0 ml) Vasoxine by intramuscular injection.

Children: 80 mcg Vasoxine per kg bodyweight intravenously.
250 mcg Vasoxine per kg bodyweight by intramuscular injection.

A second dose should not be injected until the first dose has ceased to act.

Contra-indications, warnings, etc

Contra-indications: Vasoxine is contra-indicated in cases of pre-existent severe hypertension.

Precautions: The effect of increased arterial pressure on a patient with pre-existing vascular disease or myocardial impairment should be considered before administering Vasoxine.

An exaggerated response to methoxamine may be

expected in patients with hyperthyroidism: in patients who have received treatment with monoamine oxidase inhibitors within the previous two weeks, and in hypertensive patients with temporarily lowered arterial pressure due to spinal anaesthesia. The initial dosages should be decided accordingly.

Methoxamine should not be administered unless facilities are available to make repeated arterial pressure measurements.

The use of Vasoxine in combination with local anaesthetics to prolong their action at local sites is not recommended.

Methoxamine has been reported as curtailing ventricular dysrhythmias usually in conditions associated with hypotension such as after myocardial infarction. The mode of action is almost certainly only indirect and related to improved perfusion resulting from a higher perfusion pressure. This is not a recommended indication for methoxamine and its use in such situations depends entirely on the discretion of the attending physician.

Concomitant use of Vasoxine with sympathomimetic agents, such as decongestants, some appetite suppressants and amphetamine-like psychostimulants or with monoamine oxidase inhibitors, which interfere with the catabolism of sympathomimetic amines, may cause an exaggerated response to methoxamine. Appropriate care should be taken therefore when administering methoxamine to patients who have received such drugs.

Side- and adverse effects: Subjective effects reported by patients receiving methoxamine include dull headaches, feelings of cold and other skin sensations resulting from piloerection, sensation of fullness in neck and chest and a desire to micturate.

Adrenergic receptor stimulation is inevitable but the unsought objective effects have little clinical importance.

Bradycardia may be excessive during the use of methoxamine. This can be abolished by 0.8 mg atropine given intravenously. This dosage may be reduced as appropriate for children.

Projectile vomiting may occur particularly after high dosage.

Topical methoxamine decongests mucous membrane but the effect is not usually apparent with the dose given systemically.

Use in pregnancy and lactation: When considering administering Vasoxine during pregnancy, any potential risk to which the foetus may be exposed must be weighed against the risk of the maternal disease process. (No record of use in human pregnancy is available. Vasoxine is poorly absorbed orally and is unlikely to present a problem to the breast-fed infant.)

Toxicity and treatment of overdosage: In cases of overdosage with methoxamine, when after waiting a appropriate time blood pressure has not returned to normal, management of associated hypertension can be achieved by phentolamine (5 mg) being administered intravenously and repeated as necessary.

Pharmaceutical precautions Store below 25°C. Do not freeze.

Legal category POM.

Package quantities Box of 5 ampoules.

Further information Because methoxamine is active only on alpha-adrenergic receptors it has little direct effect on cardiac adrenoceptors which are predominantly beta. Hence it is appropriate for use with

halogenated anaesthetics which cause beta receptor sensitisation.

Methoxamine has no central nervous system activity.

Product licence number 0003/5066.

ZYLORIC® TABLETS

ZYLORIC-300® TABLETS

Presentation Zyloric Tablets each contain 100 mg allopurinol BP imprinted Zyloric 100 and coded U4A. Creamy white in colour. Zyloric-300 Tablets each contain 300 mg Allopurinol BP imprinted Zyloric 300 and coded C9B. Creamy white in colour.

Uses

Conditions of excess body urate including gout: Zyloric is used to reduce urate levels in the body when these levels are excessive (serum is theoretically saturated with urate at a concentration between 0.38–0.42 mmol/l (6.4–7.0 mg%)). The higher levels seen in practice may be accounted for by (a) the formation of supersaturated solutions; (b) protein binding of urate. Excess body urate may be indicated by hyperuricaemia and/or hyperuricosuria. It may lead to deposition of urate in the tissues or it may be present with no obvious signs or symptoms.

Its main clinical manifestations of urate deposition are: gouty arthritis, skin tophi and/or renal involvement. Excess body urate is frequently of idiopathic origin but may also be found in association with other conditions including the following: neoplastic disease and its treatment; certain enzyme disorders (in particular Lesch-Nyhan syndrome); renal failure; renal calculus formation; uretic therapy and psoriasis.

Calcium renal lithiasis: Zyloric is of benefit in the prophylaxis and treatment of calcium renal lithiasis in patients with raised serum or urinary uric acid.

Allopurinol and its major metabolite, oxipurinol, act by inhibiting the enzyme xanthine oxidase which catalyses the end stage of the metabolism of purines to uric acid. Allopurinol and its metabolites are excreted by the kidney at the renal handling is such that allopurinol has a plasma half-life of about one hour whereas that of oxipurinol exceeds 18 hours. Thus therapeutic effect may be achieved by once-a-day dosage.

Dosage and administration **Adults:** The initial dosage should be in the range 100–300 mg per day which may be taken as a single dose. Doses in excess of 300 mg could be administered in divided doses. It has rarely been found necessary to exceed 900 mg per day. The dose should be adjusted by monitoring serum uric acid and/or urinary uric acid levels at appropriate intervals until the desired effect is attained, which may take one to three weeks. The maintenance dose is normally 200–300 mg per day.

Children: 10–20 mg/kg bodyweight/day.

Use in children is mainly indicated in malignant conditions especially leukaemia, and certain enzyme disorders (e.g. Lesch-Nyhan syndrome).

Initiation of therapy: In early stages of treatment with Zyloric, as with the uricosuric agents, an acute attack of gouty arthritis may be precipitated. Therefore it is advisable to give a prophylactic dose of a suitable anti-inflammatory agent or colchicine for at least one month.

Use with uricosurics: As Zyloric does not interfere with the action of uricosuric agents, they may be given

concurrently. When changing from uricosuric therapy to Zyloric, one to three weeks overlap of treatments is recommended to ensure a continuous hypouricaemic effect.

To prevent acute uric acid nephropathy in neoplastic conditions, treatment with Zyloric should precede treatment with cytotoxic drugs (see also sections under *Contra-indications, warnings, etc.*).

Dose recommendations in impaired renal function: Since allopurinol and its metabolites are excreted via the kidney, impairment of renal function may lead to retention of the drug and its metabolites with consequent prolongation of action. Thus the amount and frequency of the dosage may require reduction as indicated by monitoring serum uric acid levels. The following schedule is provided for guidance in adults.

If creatinine clearance exceeds 20 ml/minute – give standard dose.

If creatinine clearance is between 20 and 10 ml/minute – give 100–200 mg/day.

If creatinine clearance is less than 10 ml/minute – give 100 mg/day or at longer intervals.

Dose recommendations in renal dialysis: Allopurinol and its metabolites are removed by renal dialysis. If frequent dialysis is required, an alternative schedule of 300–400 mg Zyloric after each dialysis, with none in the interim, should be considered.

Contra-indications, warnings, etc

Contra-indications: Known intolerance of allopurinol. Zyloric is contra-indicated as a treatment for the acute attack of gout. Prophylactic therapy may be started when the acute attack has completely subsided, provided anti-inflammatory agents are also taken.

Precautions: Treatment with Zyloric should not be started during an attack of gout. When Puri-Nethol® (6-mercaptopurine) or Imuran® (azathioprine) is given concurrently with Zyloric, only one quarter of the usual dose of Puri-Nethol or Imuran should be given because inhibition of xanthine oxidase will prolong their activity. There is no unequivocal evidence that Zyloric potentiates the activity of other cytotoxic drugs. A reduction of dosage should be considered in the presence of severe renal or hepatic disorders.

Side- and adverse effects: Adverse reactions in association with Zyloric are usually rare and mostly of a minor nature. The incidence is higher in the presence of renal and/or hepatic disorders.

In the early stages of treatment with Zyloric, as with the uricosuric agents, an acute attack of gouty arthritis may be precipitated. Therefore it is advisable to give a prophylactic dose of a suitable anti-inflammatory agent or colchicine for at least one month.

Although there is no evidence that the interaction between allopurinol and the coumarins seen under experimental conditions has any clinical significance, this possibility should be borne in mind when a patient on anticoagulants is given Zyloric. If Zyloric is given concomitantly with chlorpropamide when renal function is poor, there may be an increased risk of prolonged hypoglycaemic activity.

Skin reactions: These are the most common reactions and may occur at any time during treatment. They may be pruritic, maculopapular, sometimes scaly or purpuric and rarely exfoliative. Zyloric should be withdrawn immediately should such reactions occur. After recovery from mild reactions Zyloric may, if desired, be reintroduced at a low dose (e.g. 50 mg/day) which may be

gradually increased. If the rash recurs, Zyloric should be permanently withdrawn.

Generalised hypersensitivity: Exfoliative skin reactions associated with other signs of hypersensitivity including fever, lymphadenopathy, arthralgia and eosinophilia occur rarely. If they do occur, it may be at any time during treatment, Zyloric should then be withdrawn immediately and permanently. Corticosteroids may be beneficial in overcoming such reactions. Patients manifesting generalised hypersensitivity reactions usually have pre-existing renal and/or hepatic disorders.

Gastro-intestinal disorder: Nausea and vomiting have been reported. This reaction is not a significant problem and can be avoided by taking Zyloric after meals.

Blood and lymphatic system: There have been occasional reports of transient reduction in the numbers of circulating formed elements of the blood, usually in association with pre-existing renal and/or hepatic disorders. The clinical significance has yet to be demonstrated.

Miscellaneous: Exacerbation of acute gouty attacks may occur in the early stages of hypouricaemic therapy (see section under *Dosage and administration*). In those conditions where the body's miscible urate pool is greatly increased (e.g. malignant disease and its treatment; Lesch-Nyhan syndrome), the rise in the xanthine concentration resulting from the action of Zyloric may lead to tissue deposition of xanthine. Fluid intake should ensure adequate urinary output. Xanthine crystals have been seen in muscle tissue of patients receiving allopurinol, but this appears to have no clinical significance.

The following complaints have been reported occasionally, but do not appear to have a clear cause and effect relationship with allopurinol; fever, general malaise, headache, vertigo, somnolence, taste perversion, hepatic necrosis, granulomatous hepatitis, abnormal liver function tests, hyperlipaemia, visual disorder, cataracts, macular changes, neuropathy, impotence, diabetes mellitus, furunculosis, alopecia, hypertension, haematuria, oedema.

Use in pregnancy and lactation: High dose intraperito-

neal allopurinol in mice has been associated with foetal abnormalities but extensive animal studies with oral allopurinol have shown none. In human pregnancy there is no evidence that Zyloric taken orally causes foetal abnormalities; however, as with all drugs, due caution should be exercised in the use of Zyloric in pregnancy. No data are available on the excretion of allopurinol and its metabolites in human breast milk.

Toxicity and treatment of overdosage: No reports of overdosage or acute intoxication are available. The most likely reaction would be gastro-intestinal intolerance. Massive absorption of Zyloric may lead to considerable inhibition of xanthine oxidase activity which should have no untoward effects unless 6-mercaptopurine and/or azathioprine is being taken concomitantly. In this case the risk of increased activity of these drugs must be recognised. Adequate hydration to maintain optimum diuresis facilitates excretion of allopurinol and its metabolites. Dialysis may be resorted to if considered necessary.

Pharmaceutical precautions Store below 25°C. Keep dry.

Legal category POM.

Package quantities *Zyloric Tablets:* bottle of 10 tablets.

Zyloric-300 Tablets: Calendar pack of 2 x 14 tablets.

Further information Zyloric presents definite advantages over uricosuric agents or simple anti-inflammatory drugs, especially in patients with gouty nephropathy, in those who form renal urate stones and those with unusually severe disease. In most patients with extensive tophaceous deposits, progressive formation of tophi has been halted and draining urate sinuses have healed.

***Trade Mark**

CUPAN*

Presentation *Acupan Tablets*: White, film-coated, circular, biconvex tablets, 7 mm in diameter, marked PN on one side. Each tablet contains nefopam hydrochloride 30 mg.

Acupan Injection: Each 2 ml ampoule contains 1 ml of solution of nefopam hydrochloride 20 mg/ml.

Uses *Acupan* is indicated for the relief of acute and chronic pain, including: post-operative pain; dental pain; musculo-skeletal pain; acute traumatic pain and cancer pain.

Acupan is a potent and rapidly-acting analgesic. It is totally distinct from other centrally-acting analgesics such as morphine, codeine, pentazocine and propoxyphene.

Unlike the narcotic agents, *Acupan* has been shown not to cause respiratory depression. There is no evidence from pre-clinical research of habituation occurring with *Acupan*.

Dosage and administration *Adults: Acupan Tablets*: Dosage may range from 1 to 3 tablets three times daily depending on response. The recommended starting dosage is 2 tablets three times daily.

Acupan Injection: 20 mg (1 ml) intramuscularly or intravenously repeated if necessary every six hours (see instructions for administration). Onset of effect after intramuscular injection is within 15–20 minutes and peak effect is reached at one to one-and-a-half hours after administration.

Treatment started with *Acupan* injection may be continued with *Acupan* Tablets. 60 mg *Acupan* (2 tablets) is approximately bioequivalent to 20 mg (1 ampoule) given by injection.

Instructions for administration of *Acupan* Injection: *Acupan* Injection should always be given with the patient lying down. When given intramuscularly, aspiration should be performed before injection to ensure that the needle is not in a blood vessel. When given intravenously, the injection should be given *slowly* through a 26 gauge needle at a rate not exceeding 5 mg per minute (four minutes for 20 mg). After injection by either the intramuscular or intravenous route the patient should remain lying down for 15–20 minutes. The patient could then get up slowly. Too rapid administration of the injection can give rise to syncope.

Children: Since *Acupan* has not been evaluated in children no dosage recommendation can be given for children under 12 years.

Contra-indications, warnings, etc *Side-effects*: Drowsiness, nervousness, dry mouth and lightheadedness may occur. Less frequently, vomiting, blurred vision, dizziness, sweating, insomnia, headache and tachycardia have been reported.

Interaction: The side-effects of *Acupan* may be additive to

those of other agents with anticholinergic or sympathomimetic activity. It should not be used in the treatment of myocardial infarction since there is no clinical experience in this indication. Hepatic and renal insufficiency may interfere with the metabolism and excretion of nefopam. Caution should be exercised when nefopam is administered concurrently with tricyclic antidepressants.

Contra-indications: *Acupan* is contra-indicated in patients with a history of convulsive disorders and should not be given to patients taking mono-amine-oxidase (MAO) inhibitors.

Overdosage: A few cases of overdosage with *Acupan* have been reported and successfully treated. Treatment should consist of general supportive measures. Diazepam should be given, preferably by mouth, if CNS excitement occurs.

In dogs given abnormally high doses of paracetamol, correspondingly excessive doses of nefopam potentiated the known hepatotoxicity of paracetamol. These studies indicated that repeated oral doses of 236 mg/kg/day of paracetamol with 24 mg/kg/day of nefopam showed potentiation of paracetamol hepatotoxicity. These doses are about six to eight times higher than the average human doses. Lower doses equivalent to three to four times the human dose produced no evidence of hepatotoxicity potentiation.

Pharmaceutical precautions No special storage precautions are required.

Package quantities *Acupan Tablets*: Bottles of 30 and 100 tablets.

Acupan Injection: Boxes containing 5 x 2 ml ampoules filled with 1 ml of solution.

Legal category POM.

Further information Nil.

Acupan Injection 0068/0069

DIFFLAM* CREAM ▼

Presentation *Difflam* is a white, pleasant-smelling cream, containing benzydamine hydrochloride 3% w/w.

Uses *Difflam* cream is a topical analgesic and anti-inflammatory treatment for the relief of symptoms associated with painful inflammatory conditions of the musculo-skeletal system, including:

Acute inflammatory disorders such as myalgia and bursitis.

Traumatic conditions such as sprains, strains, contusions and the after-effects of fractures.

Difflam cream is well absorbed through the skin. It

concentrates in inflamed tissue where it has been shown to have anti-inflammatory and local anaesthetic actions.

Dosage and administration Difflam cream should be massaged lightly into the affected area three times daily and at the discretion of the doctor, up to six times daily in more severe conditions.

Contra-indications, warnings, etc *Side-effects:* Benzydamine is very well tolerated; the only adverse effect that occurred in clinical studies was a local skin reaction which varied from erythema to a papular eruption; the incidence was low (less than two per cent of patients) and the skin returned to normal on stopping treatment.

Caution: To avoid possible irritation, Difflam cream should be kept away from eyes and mucosal surfaces.

Overdosage: Difflam is unlikely to cause adverse systemic effects, even if accidental ingestion should occur. No special measures are required.

Pharmaceutical precautions Avoid extremes of temperature.

Legal category P.

Package quantities Tube containing 30 g.

Further information Nil.

Product licence number 0068/0088.

DIFFLAM* ORAL RINSE ▼

Presentation Difflam Oral Rinse is a pleasant tasting, clear, green solution, containing benzydamine hydrochloride 0.15% w/v.

Uses Difflam Oral Rinse is a locally acting analgesic and anti-inflammatory treatment for the relief of painful inflammatory conditions of the mouth and throat including:

Traumatic conditions: Pharyngitis following tonsillectomy or the use of a naso-gastric tube; dental surgery;

Inflammatory conditions: Pharyngitis, aphthous ulcers and oral ulceration due to radiation therapy.

Benzydamine is absorbed into inflamed tissue. It is a unique preparation which concentrates in inflamed tissue, where it exerts an anti-inflammatory and analgesic action by stabilising the cellular membrane and inhibiting prostaglandin synthesis.

Dosage and administration Rinse or gargle with 15 ml (approximately 1 tablespoonful) every 1½ to 3 hours as required for pain relief. Not suitable for children aged 12 years or under. The solution should be expelled from the mouth after use. Difflam Oral Rinse should generally be used undiluted, but if 'stinging' occurs the rinse may be diluted with water. Uninterrupted treatment should not exceed seven days, unless under medical supervision.

Contra-indications, warnings, etc *Side-effects:* Benzydamine is well tolerated; side-effects are minor. Occasionally, oral tissue numbness or 'stinging' sensations may occur.

Overdosage: Difflam is unlikely to cause adverse systemic effects, even if accidental ingestion should occur. No special measures are required.

Pharmaceutical precautions Do not leave the uncartoned bottle in direct sunlight.

Legal category P.

Package quantities Bottle containing 200 ml

Further information Nil.

Product licence number 0068/0096.

DUROMINE*

Presentation Duromine is available in two strengths. Each capsule contains phentermine 15 mg or 30 mg as an ion-exchange resin complex.

Duromine 15 mg: Opaque green-grey size No. 3 capsules printed Duromine 15.

Duromine 30 mg: Opaque maroon-grey size No. 1 capsules printed Duromine 30.

Uses Duromine is an appetite-depressant and is indicated in all types of simple obesity.

Phentermine is a sympathomimetic amine with marked anorectic activity. In efficacy it compares favourably with amphetamine, but it produces much less CNS excitation.

After ingestion, the medicament is gradually released from the ion-exchange resin complex over a period of 10–14 hours. Therapeutic blood levels are reached within one hour of administration and are maintained by the continuous and smooth release of phentermine from the resinate. This smooth and prolonged activity avoids peaking of blood level concentrations and minimises the chance of adverse CNS reactions.

Dosage and administration *Adults:* One 15 mg or 30 mg capsule daily at breakfast time.

Children: 6–12 years: One 15 mg capsule daily at breakfast time.

Duromine is not recommended for children under the age of six.

Contra-indications, warnings, etc *Side-effects:* Slight dryness of the mouth or a tendency to early waking may be experienced at higher dosage.

Caution: Duromine should be used with caution in patients under treatment with antihypertensive agent since it may cause some loss of blood pressure control.

Contra-indications: Duromine is contra-indicated in patients under treatment with monoamine-oxidase (MAO) inhibitors.

Overdosage: Symptoms: Initially irritability, agitation, disorientation and tremor may occur, followed by cardiac arrhythmias, convulsions, hallucinations and coma.

Treatment: The stomach should be emptied by emesis or stomach tube and washed out with water if the preparation has been ingested within the last three or four hours. Diazepam, preferably by mouth (cautiously by intravenous injection) should be used to control marked excitement and convulsions. Provided renal function is adequate, elimination of phentermine may be assisted by acidification of the urine by agents such as lysine hydrochloride or arginine hydrochloride.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Duromine 15 mg: Bottles of 3 capsules.

Duromine 30 mg: Bottles of 30 capsules.

Further information Nil.

5 mg 0068/5055

0 mg 0068/5056

HIPREX*

Representation White, oblong tablet with breakline, marked HX on one side. Each Hiprex tablet contains methenamine hippurate 1 g.

Uses

Hiprex is indicated in the prophylaxis and treatment of urinary tract infections:

1. As maintenance therapy after successful initial treatment of acute infections with antibiotics.
2. As long-term therapy in the prevention of recurrent cystitis.
3. To suppress urinary infection in patients with indwelling catheters and to reduce the incidence of catheter blockage.
4. To provide prophylaxis against the introduction of infection into the urinary tract during instrumental procedures.
5. Asymptomatic bacteriuria, including bacteriuria of pregnancy.

Methenamine hippurate is readily absorbed from the gastro-intestinal tract and excreted via the kidney.

With Hiprex, as with other specific urinary antibacterial agents of this type, antibacterial activity is confined to the urinary tract. The chemical structure of methenamine hippurate is such that a two-fold antibacterial action is obtained:

1. The slow release of the bactericidal formaldehyde, from the methenamine part, in the urine; acid pH is necessary for this reaction to occur. It is obtained and maintained there by the presence of hippuric acid.
2. The bacteriostatic effect of hippuric acid itself on urinary tract pathogens.

Hiprex has a wide antibacterial spectrum covering both gram-positive and gram-negative organisms. It is active against the bacteria which most commonly cause urinary tract infection – *Escherichia coli*, *Aerobacter*

aerogenes, *Pseudomonas* and some strains of *Proteus*. Urinary antibacterial activity can be shown within 30 minutes of administration.

Hiprex is particularly useful for long-term treatment because neither tolerance to its effect nor bacterial resistance occurs. The incidence of side-effects is extremely low.

Dosage and administration *Adults*: 1 g twice daily.

In patients with catheters the dosage may be increased to 1 g three times daily.

Children: 6–12 years: 500 mg twice daily.

The tablets may be halved, or they can be crushed and taken with a drink of milk or fruit juice if the patient prefers.

Contra-indications, warnings, etc *Side-effects*: Occasionally rashes, gastric irritation or irritation of the bladder may occur.

All side-effects are reversible on withdrawal of the drug.

Contra-indications: Hepatic insufficiency, severe dehydration, metabolic acidosis, or severe renal failure (serum creatinine > 5 mg%). Hiprex may be used where mild to moderate renal insufficiency is present.

Hiprex should not be administered concurrently with sulphonamides because of the possibility of crystalluria, or with alkalinising agents, such as mixture of potassium citrate.

Overdosage: Vomiting and haematuria may occur. Bladder symptoms can be treated by the consumption of copious quantities of water and 2–3 teaspoonfuls of bicarbonate of soda.

Pharmaceutical precautions The container should be kept tightly closed.

Legal category P.

Package quantities Bottles of 100 tablets.

Further information Nil.

Bloomsbury Square
London WC1B 4EB

HORMONIN*

Presentation Each pink tablet contains:

Oestriol	0.27 mg
Oestradiol	0.6 mg
Oestrone	1.40 mg

Uses Hormonin has been designed for replacement therapy in oestrogen-deficiency states, particularly those associated with the menopause such as nocturnal sweating, vasomotor disturbances, psychological upsets, atrophic vaginitis and pruritus vulvae. By maintaining the physiological levels of the three naturally occurring human oestrogens, Hormonin helps to prevent these symptoms that are associated with the menopause.

Dosage and administration Hormonin is given by mouth. The dosage for the relief of menopausal symptoms range from 2 tablets per day to $\frac{1}{2}$ tablet per day or 1 tablet on alternate days, depending upon the severity of the symptoms. In general, the maximum dosage is required for not more than two weeks to initiate therapy. Where it is necessary to control irregular cycles in women approaching the menopause, a dosage of 1 tablet daily is usually adequate.

For prophylactic use in post-menopausal women, a dosage of 1 tablet is recommended daily or on alternate days, according to the needs of the individual patient. Cyclic therapy may be used.

Contra-indications, warnings, etc Hormonin is contra-indicated in patients with pre-existing genital cancer or primary cancer of the breast. A very small proportion of women may complain of a sense of fullness or slight pain in the breasts. This is usually controlled by stopping therapy on alternate days, or, in post-menopausal women, for one week each month. Oestrogens should not be administered to women with recurrent mastitis or abnormal mammograms except in instances where the physician feels that treatment is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed oestrogen neoplasia. A complete pre-treatment physical examination should be followed with special reference to the pelvis and breast. Oestrogen-withdrawal bleeding during cyclic therapy of women patients is a natural occurrence. However, irregular uterine bleeding or spotting should always be thoroughly investigated. The physician should be alert to the earliest manifestation of thrombotic disorders. Should this problem occur, discontinue oestrogen therapy immediately. Pre-existing fibromyomata may increase in size while using oestrogen. For this reason, patients should be examined at regular intervals. Prolonged use might increase the risk of the development of endometrial carcinoma.

Pharmaceutical precautions The product should be stored where there is not excessive heat, moisture or light.

Legal category POM.

Package quantities Securitainers of 100 tablets.

Further information Nil.

Product licence number 0271/5000.

MIDRID*

Presentation Each scarlet Midrid capsule contains:

Isometheptene mucate	65 mg
Dichloralphenazone	100 mg
Paracetamol	325 mg

Uses In the treatment of vascular headaches, including migraine and tension headaches. Midrid contains iso metheptene, a cerebral vasoconstrictor, which provide prompt relief of vascular head-pain by reducing the underlying cerebrovascular disturbances. Midrid also contains dichloralphenazone, which is a sedative/tranquilliser.

The addition of paracetamol in Midrid is designed to bring relief to the throbbing head-pain of migraine; this is the first consideration of the patient. Acting centrally it raises the pain threshold between the thalamus and the cortex, in doses that produce few, if any, other central or peripheral effects.

Dosage and administration *Treatment of migraine headache:* 2 capsules at once, followed by 1 capsule every hour until relief is obtained. Up to 5 capsules with a 12-hour period.

Treatment of tension headache: 2 capsules at once followed by 1 or 2 capsules every four hours. Up to 6 capsules a day. Administration is by the oral route.

Contra-indications, warnings, etc

Contra-indications: Midrid is contra-indicated in severe renal, hepatic or organic heart disease, severe hypertension, glaucoma, and in those patients who are on monoamine-oxidase inhibitor therapy.

Side-effects; Transient dizziness may appear in hypersensitive patients. This can usually be eliminated by reducing the dose.

Overdosage; No specific antidote. Gastric lavage plus appropriate supportive treatment.

Pharmaceutical precautions Store in a close container away from excessive moisture, heat or light.

Legal category POM.

Package quantities Securitainers of 50 capsules.

Further information Nil.

Product licence number 0271/5001.

*Trade Mark

EUGLUCON®

Presentation Euglucon is available as:

1. White, circular, biconvex tablets, 6 mm in diameter, marked EU on one side and 2.5 on the reverse. Each tablet contains 2.5 mg Glibenclamide BP.

2. White, oblong 10 mm x 5 mm tablets containing 5 mg Glibenclamide BP. Each side has a breakline and is inscribed BM/EU, such that when a tablet is broken into half, one side is marked BM, and the other EU.

Uses Euglucon is an oral hypoglycaemic agent of the sulphonylurea type.

Euglucon is indicated for the treatment of maturity-onset diabetes which is not adequately controlled by dietary measures alone.

Dosage and administration Euglucon should be taken with or immediately after food. The total daily dosage is preferably given as a single dose at breakfast with the first main meal, but due consideration should be given to the patient's meal habits and daily activity when apportioning dosage.

New Diabetics. In maturity-onset diabetes of mild to moderate severity, treatment should be started with 5 mg daily or 2.5 mg in debilitated or elderly patients. If this dosage is not sufficient for proper control it should be increased by 2.5 mg at intervals of one week, or as directed by the clinician. The total daily dose of Euglucon rarely exceeds 15 mg. Increasing dosage beyond this level is unlikely to produce further response.

Transfer from other sulphonylureas: Transfer to Euglucon can usually be carried out without any break in therapy.

Euglucon treatment should be started with 5 mg daily and, if necessary, adjusted in steps of 2.5 or 5 mg. A dose of 5 mg Euglucon is approximately equivalent to 1,000 mg tolbutamide, 250 mg chlorpropamide, 25 mg libornuride or 5 mg glipizide.

Changeover from biguanides: Euglucon treatment should be started with 2.5 mg of Euglucon and the biguanide withdrawn. Dosage should then be adjusted by increments of 2.5 mg to achieve control.

Combination with biguanides: If adequate control is not possible with diet and 15 mg of Euglucon, control can often be re-established by a combination of Euglucon and a biguanide derivative.

Euglucon and insulin: While it is appreciated that most patients who are on insulin therapy will continue to need it, there may be a few patients, particularly those on low daily dosages, who will remain stabilised if transferred to Euglucon.

No dosage recommendations can be made for the administration of Euglucon to children.

Contra-indications, warnings, etc Euglucon is contra-indicated in:

1. The treatment of juvenile or unstable diabetes.

2. Patients who have had serious metabolic decompensation with ketosis and, in particular, diabetic pre-coma and coma.

3. Serious impairment of renal, hepatic, thyroid or adrenocortical function.

4. Pregnancy. After delivery. Euglucon therapy can be started or resumed.

Precautions: The hypoglycaemic action of oral anti-diabetic agents including Euglucon may be enhanced by sulphonamides, salicylates, phenylbutazone, coumarin derivatives, beta-blocking agents, monoamine-oxidase inhibitors, cyclophosphamide, chloramphenicol and tuberculostatics. Conversely, thiazide diuretics, frusemide, ethacrynic acid, oral contraceptives containing oestrogens, and corticosteroids may diminish hypoglycaemic activity.

In patients suffering from intercurrent infections or trauma, the dosage of Euglucon may need to be increased. If such complications are severe, diabetic control may be lost necessitating withdrawal of Euglucon and maintenance of diabetic control with insulin. Euglucon should be re-introduced when the patient has recovered from the infection or trauma.

Side-effects: Euglucon is well tolerated and side-effects serious enough to necessitate withdrawal are uncommon. Gastro-intestinal symptoms (nausea, anorexia and diarrhoea) are uncommon and allergic skin reactions are seldom encountered.

Reversible leucopenia and thrombocytopenia have been reported but are rare. Transient changes in liver enzyme concentrations and liver function tests during treatment with glibenclamide have been reported, but these are not known to be directly attributable to the product. As with other agents, hypoglycaemia can occur with Euglucon, but is not usually prolonged and responds to appropriate therapeutic measures.

Effects of overdosage and their treatment: If a hypoglycaemic reaction should occur, the conscious patient may be treated with dextrose or 3–4 lumps of table sugar with water. This may be repeated, if necessary, in 15 minutes.

If the patient is comatose, sucrose or dextrose may be given by stomach tube or dextrose given intravenously. Glucagon may be administered in a dose of 1 mg subcutaneously or intramuscularly to produce consciousness.

Pharmaceutical precautions No special storage requirements.

Legal category POM.

Package quantities 5 mg tablets: Blister packs of 100.

2.5 mg tablets: Blister packs of 100.

Further information Absorption studies in healthy human volunteers using labelled glibenclamide formu-

lated as Euglucon tablets showed a mean absorption of $84 \pm 9\%$.

Excretion was approximately 50% in the urine and 50% in the faeces. Absorbed glibenclamide was completely metabolised and the three isolated metabolites in the concentrations found had no significant hypoglycaemic activity.

Euglucon 5 mg Tablets 0109/5023

PROCTOFIBE* ▼

Presentation Proctofibe is available as beige biconvex film-coated tablets, 12 mm in diameter, each containing 375 mg of a fibrous extract of grain and 94 mg of a fibrous extract of citrus.

Uses Colonic and gastro-intestinal disorders where a high-fibre regimen is indicated including uncomplicated diverticular disease, irritable colon, simple constipation, haemorrhoidal disorders, anal fissure, pregnancy, myocardial infarction and other conditions where straining at stool should be avoided.

Dosage and administration *Adults:* 4–12 tablets daily in divided doses, or as directed by the physician.

Children: Over three years of age, as adults.

The tablets should be swallowed with ample water. (Alternatively, they may be crushed and dispersed in water.)

Contra-indications, warnings, etc Intestinal obstruction, gluten enteropathies, coeliac disease. As with other fibre presentations, transient bloating and flatulence may occasionally be reported in the first two weeks of treatment.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities Bottles of 125 tablets.

Further information Nil.

Product licence number 0109/0081.

PROCTOSEDYL*

Presentation Proctosedyl is available as smooth, off-white suppositories and as an odourless, yellowish-white, translucent, greasy ointment. Each suppository or gram of ointment contains the following active ingredients.

Cinchocaine Hydrochloride BP	5 mg
Hydrocortisone BP	5 mg
Framycetin Sulphate BP (Soframycin)	10 mg
Aesculin	10 mg

Uses The local anaesthetic cinchocaine relieves pain and relaxes sphincteric spasm. Pruritus and inflammation are relieved by hydrocortisone, which also decreases serous discharge, while Soframycin controls local infection (a cause of inflammation and irritation).

Proctosedyl is thus used for the following: internal and external haemorrhoids; prophylaxis between attacks to prevent recurrences; haemorrhoidal complications—anal pruritus, perianal eczema, proctitis, fissure; pre-operative and post-operative treatment of haemorrhoidectomy patients; post-partum haemorrhoidal conditions.

Dosage and administration A suppository is inserted morning and evening, and after each stool.

Apply the ointment in small quantity with the finger on the painful or pruritic area, morning and evening and after each stool. For deep application attach cannula to tube, insert to full extent and squeeze tube gently from lower end whilst withdrawing.

The ointment may be used separately or concurrently with the suppositories.

Contra-indications, warnings, etc Known hypersensitivity to any of the ingredients.

In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

As with all preparations containing topical corticosteroids, the possibility of systemic absorption should be considered. In particular, long-term continuous therapy should be avoided in infants. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions Store cool.

Legal category POM.

Package quantities *Proctosedyl Suppositories* Packs of 12.

Proctosedyl Ointment: Tubes of 15 g and 30 g (with cannula).

Further information Nil.

SURGAM* ▼

Presentation White, convex tablets, 10 mm in diameter, marked SURGAM 200 on one side and  on the reverse. Each tablet contains 200 mg tiaprofenic acid.

Uses *Properties:* Surgam is a non-steroidal anti-inflammatory agent with marked analgesic properties.

Indications: Rheumatoid arthritis, osteoarthritis; low back pain; musculo-skeletal disorders such as fibrositis, capsulitis, epicondylitis and other soft-tissue inflammatory conditions; sprains and strains, post-operative inflammation and pain and other soft-tissue injuries.

Dosage and administration *Adults:* 600 mg daily in divided doses.

Children: There are insufficient data to recommend use of Surgam in children.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulceration, hypersensitivity to the drug.

Precautions: Surgam should be used with care in patient with a history of peptic ulceration, severe renal or hepatic insufficiency, asthma or previous sensitivity to aspirin or other non-steroidal anti-inflammatory agents. Since Surgam is highly protein-bound, it may be necessary to modify the dosage of other highly protein-bound drugs; e.g. anticoagulants, sulphonamides, hypoglycaemic agents, phenytoin and certain potent diuretics when these are administered concurrently.

Pregnancy: Although animal studies have not revealed evidence of teratogenicity, safety in human pregnancy and lactation cannot be assumed and, in common with other non-steroidal anti-inflammatory agents, administration during the first trimester should be avoided.

Lactation: There are no data on the passage of Surgam into the breast milk.

Side effects: Surgam is generally well tolerated. However, there have been occasional reports of gastrointestinal upset, headache, drowsiness and skin rash.

Treatment of overdosage: In the event of overdosage with Surgam, supportive and symptomatic therapy is indicated.

Pharmaceutical precautions Store in a cool place and protect from light.

Legal category POM.

Package quantities 200 mg tablets in bottles of 100.

Further information Nil.

Product licence number 0109/0108.

RYTHMODAN* CAPSULES

RYTHMODAN* RETARD TABLETS ▼

RYTHMODAN INJECTION

Presentation *Oral.*

Rythmodan Capsules: Capsules with opaque green cap and opaque yellow body with 'RY' and 'RL' printed in black, containing 100 mg of disopyramide base.

Capsules with opaque white cap and body with 'RY' and '150' printed in black, containing 150 mg disopyramide base.

Rythmodan Retard Tablets: White, circular biconvex tablets, 12 mm in diameter, film-coated with a break line. Tablets are marked 'RY' and 'R' on one side and  on the reverse. Each tablet contains disopyramide phosphate equivalent to 250 mg disopyramide base in a sustained release formulation.

Intravenous Injection.

Rythmodan Injection: Ampoules for intravenous use only, 5 ml ampoules containing disopyramide phosphate equivalent to 50 mg disopyramide base in solution.

Uses Properties: Rythmodan is able to prevent and control a wide variety of cardiac arrhythmias probably by slowing conduction in the His-Purkinje system and by increasing the effective refractory period of the atria and ventricles.

Indications Oral Rythmodan is indicated in:

1. Maintenance of normal rhythm following conversion by Rythmodan Injection, other parenteral drugs or electroconversion.
2. Prevention of arrhythmias after myocardial infarction.
3. Treatment of persistent ventricular and atrial extrasystoles, paroxysmal supraventricular tachycardia, Wolff-Parkinson-White syndrome.
4. Suppression of arrhythmias during surgical procedures.
5. Control of arrhythmias following the use of digitalis or similar glycosides.

Rythmodan Injection is intended for intravenous use only and is indicated in the following conditions:

1. Conversion of ventricular and supraventricular

arrhythmias after myocardial infarction, including those not responding to lignocaine or other i.v. treatment.

2. Control of ventricular and atrial extrasystoles, supraventricular tachycardia, and Wolff-Parkinson-White syndrome.

3. Control of arrhythmias following digitalis or similar glycosides when Rythmodan cannot be administered orally.

Dosage and administration *Oral Rythmodan*

Capsules: The recommended daily dosage in adults is 300–800 mg in divided doses adjusted according to the response of the patient.

Rythmodan Retard Tablets: The recommended dose for stabilised patients or those receiving Rythmodan for the first time is 1 to 1½ tablets (250–375 mg) twice daily. Patients being transferred from intravenous therapy with Rythmodan should be stabilised on standard Rythmodan capsules for the first 24 hours (see below). Tablets should be swallowed and not crushed or chewed.

Intravenous Injection/Rythmodan Injection: The recommended dosage can be given by two different regimes.

1. An initial direct intravenous injection of 2 mg/kg (but not exceeding 150 mg (15 ml) irrespective of body weight) should be given SLOWLY OVER NOT LESS THAN FIVE MINUTES, i.e. the rate of injection must not exceed 30 mg (3 ml) per minute in order to reduce or avoid unwanted haemodynamic effects. If conversion occurs during this time the injection should be stopped. If the arrhythmia is to respond to Rythmodan it will usually do so within 10–15 minutes after completion of the injection.

Transfer to oral maintenance therapy is accomplished by giving 200 mg orally, immediately on cessation of intravenous administration, followed by 200 mg every 8 hours for 24 hours. Most patients may be maintained subsequently on a daily dosage of 500–750 mg of Rythmodan, preferably administered as 1 to 1½ Rythmodan Retard tablets (250–375 mg) twice daily. Where the need for lower dosage outweighs the convenience of twice daily administration, appropriate doses of conventional capsules (100 to 150 mg) may be administered.

If conversion is achieved by intravenous Rythmodan but the arrhythmia subsequently recurs, a further slow direct intravenous injection over not less than five minutes may be administered cautiously and preferably under ECG control. The total administration by the intravenous route should not exceed 4 mg/kg (maximum 300 mg) in the first hour, nor should the combined administration by the intravenous and oral routes exceed 800 mg in 24 hours.

2. An initial direct intravenous injection as above, i.e. over not less than five minutes, maintained by intravenous infusion by drip of 20–30 mg/hour (or 0.4 mg/kg/hour) up to a maximum of 800 mg daily. This regime should be employed if the patient is unable to take oral medication or in particularly serious arrhythmias being treated in coronary care units.

Heart failure: In determining the intervals between administration of Rythmodan capsules it should be borne in mind that whilst the elimination half-life in normal volunteers is approximately seven hours, in patients with heart failure, half-life values of 12 hours or more have been recorded.

Impaired renal function: Standard capsules should be used in patients in renal failure. A reduced dosage,

preferably accompanied by assay of disopyramide plasma levels in cases of severe renal failure (creatinine clearance <8 ml/min) is recommended. The following table may be helpful as a guide.

<i>Creatinine clearance (ml/min)</i>	<i>Dosage 100 or 150 mg capsules</i>
Normal	Normal dosage
20–60	100 mg 8-hourly or 150 mg 12-hourly
8–20	100 mg 12-hourly
<8	150 mg daily

Children: There are insufficient data to recommend the use of Rythmodan in children.

Contra-indications, warnings, etc

Contra-indications: Disopyramide is contra-indicated in second or third degree heart block and sinus node disease if no pacemaker is present, cardiogenic shock and severe uncompensated heart failure and hypersensitivity to disopyramide.

Warnings and precautions: There have been reports of ventricular tachycardia or ventricular fibrillation or Torsade de Pointes in patients receiving disopyramide. These have been usually, but not always, associated with significant widening of the QRS complex or prolonged QT interval. If these ECG changes or arrhythmias develop the drug should be discontinued.

Disopyramide should be used only with caution in patients with atrial flutter or atrial tachycardia with block as conversion of a partial AV block to a 1:1 response may occur. Accordingly, the need for prior digitalisation should be considered.

Owing to its negative inotropic effect, disopyramide should be used with caution in patients suffering from significant cardiac failure. Such patients should be fully digitalised or controlled with other therapy before initiating treatment with disopyramide.

The occurrence of hypotension following disopyramide administration, which has been observed especially in patients with cardiomyopathy or inadequately compensated congestive heart failure, requires prompt discontinuation of the drug. Any resumption of therapy should be at a lower dose with close patient monitoring.

The use of disopyramide in combination with other negative inotropic drugs such as beta adrenoceptor antagonists is not recommended especially in intravenous therapy.

In view of the serious nature of many of the conditions being treated it is suggested that *Rythmodan Injection should only be used when facilities exist for cardiac monitoring or defibrillation, should the need arise.*

Disopyramide should be used with caution in patients receiving concurrent therapy with diuretics likely to give rise to hypokalaemia since this may reduce patient response to disopyramide.

Disopyramide should be used with caution in the treatment of digitalis intoxication.

Care should be taken when prescribing disopyramide for patients with bundle branch block as the effect of disopyramide in this condition is unpredictable. If first degree heart block develops in a patient receiving disopyramide, dosage should be reduced and may require discontinuation if the block persists.

Since disopyramide is eliminated predominantly by glomerular filtration the dose administered to patients with significant renal impairment may require adjustment. Patients with renal impairment should not be treated with sustained release disopyramide.

Hepatic impairment causes an increase in the plasma half-life of Rythmodan and a reduced dosage may be required.

Due to its anticholinergic properties, patients with glaucoma, a tendency to urinary retention, or any patient receiving a drug with anticholinergic activity may be unsuitable for Rythmodan therapy.

Pregnancy: Although Rythmodan has undergone animal tests for teratogenicity without evidence of any effect on the developing foetus, the benefits of using Rythmodan in the first trimester of pregnancy should be weighed against possible risks.

Lactation: There are no data on the excretion of Rythmodan into human milk. However, animal studies have shown a higher concentration of Rythmodan in milk than in plasma. Therefore, if the drug is considered essential, an alternative method of infant feeding should be used.

Side effects: Rythmodan is usually well tolerated. Most common side effects (dry mouth, blurred vision, urinary hesitancy) are attributable to the drug's mild anticholinergic action. Exceptionally this may be marked. Gastrointestinal irritation may also occur. Very rarely, disopyramide therapy has been associated with acute psychosis, cholestatic jaundice and hypoglycaemia. Side effects usually disappear rapidly with reduction of dosage or cessation of therapy. Profuse sweating may indicate too rapid intravenous injection.

Overdosage: Animal studies indicate that overdosage may lead to cardiac arrest or atrio-ventricular block or to disorders of ventricular excitability leading to terminal ventricular fibrillation. Intracardiac conduction defect and ventricular hyperexcitability may be controlled by general intensive supportive therapy.

Infusion studies in dogs and man have shown the effectiveness of isoprenaline in restoring any marked fall in blood pressure.

Pharmaceutical precautions Store in a cool place. Rythmodan Injection is physically compatible with the following: Sodium Chloride Injection BP, Dextrose Injection BP, Compound Sodium Chloride Injection BP, Compound Sodium Lactate Injection BP.

Legal category POM.

***Trade Mark**

(PRESOLINE®)

Representation Apresoline Tablets each containing 5 mg hydralazine hydrochloride, circular, polished, sugar-coated tablets, pale yellow in colour, marked CIBA on one side and the letters GF on the other.

Apresoline Tablets each containing 50 mg hydralazine hydrochloride, circular, polished, sugar-coated tablets, violet-red in colour, marked CIBA on one side and the letters HG on the other.

Ampoules each containing 20 mg hydralazine hydrochloride, presented as a white lyophilised powder in a clear glass 2 ml ampoule (requiring reconstitution before use – see 'Dosage' below).

Uses *Mode of action:* Apresoline lowers blood pressure apparently by exerting an arteriolar dilating effect through a direct relaxation of vascular smooth muscle. Although the precise mechanism of action of Apresoline is not fully understood, the major effects are on the cardiovascular system, with no important effects on the central nervous system. Apresoline exerts a moderate but significant antihypertensive effect (diastolic more than systolic). Because of its selective dilating effect on arterioles, it tends to improve renal, uterine and cerebral blood flow. The effect results in a decrease in arterial blood pressure and peripheral vascular resistance, and in increase in heart rate, stroke volume and cardiac output. The rise in cardiac output accompanies the fall in blood pressure, probably as a reflex response. In patients with heart failure, these reflexes are attenuated and the improvement in cardiac output is due to afterload reduction, without accompanying tachycardia or hypotension; it also serves to improve renal blood flow and renal function.

Indications *Hypertension: Oral:* Apresoline is indicated, usually in conjunction with other anti-hypertensive agents for the treatment of moderate to severe hypertension. Especially good results are obtained in combination with a beta-adrenergic blocker such as propranolol, with base-line diuretic therapy in addition.

Parenteral: Apresoline is used intravenously to control hypertensive emergencies, particularly those associated with pre-eclampsia and toxemia of pregnancy, and in hypertension with renal complications. (See Contraindications, warnings, etc.). In hypertensive patients with normal kidneys who are treated with Apresoline, there is evidence of increased renal blood flow and a maintenance of glomerular filtration rate. In some instances improved renal function has been noted where control values were below normal prior to the administration of Apresoline.

Chronic congestive cardiac failure Apresoline is recommended in the management of moderate to severe congestive cardiac failure in patients in whom optimal doses of diuretics and cardiac glycosides are proving insufficient.

In patients with high left ventricular filling pressure, it is advisable to combine Apresoline with a nitrate.

Dosage and administration *Hypertension: Oral:* The initial dose of Apresoline is 25 mg, two or three times daily in combination with a beta-blocker plus thiazide diuretic. This may be increased to a maximum of 200 mg daily given in two or three divided doses.

Parenteral: In hypertensive emergencies, 20–40 mg should be given by slow intravenous injection or intravenous drip and repeated as necessary. The contents of the vial should be reconstituted with 1 ml of water for injection and then diluted with saline. Once reconstituted the injection must be given immediately and any remainder discarded. It is inadvisable to use dextrose solution as a vehicle for the parenteral administration of hydralazine. Apresoline for infusion can be used with a 5% sorbitol solution, or isotonic inorganic infusion solutions such as sodium chloride or Ringer's solution.

Chronic congestive cardiac failure: It is advisable to initiate therapy in hospital, with a starting dose of 25 mg three or four times daily. Dependent on the clinical response, this dose may need to be increased every second day up to a dose of 50–75 mg three to four times daily. In acute heart failure, single initial doses of 100 mg or possibly 200 mg may be required. Occasionally, where oral therapy is inappropriate, 20 mg may be given intravenously and repeated at hourly intervals depending on response.

Because of the known association of a reversible lupus like syndrome with high or prolonged dosage of Apresoline, acetylator status should be determined when maintenance therapy is established, and where appropriate ANF titre should be monitored periodically.

Contra-indications, warnings, etc *Side-effects:* Tachycardia, headache, flushing, anorexia, nausea and vomiting can occur. All these side effects may be minimised by the prior administration of a beta-blocker.

Contra-indications: Apresoline has been found to be teratogenic in mice, producing a small incidence of cleft palate and certain other minor bony malformations, in oral doses ranging from 20–120 mg/kg. Its use should therefore be avoided in the first half of pregnancy that is, during the period of organogenesis.

Apresoline should also be avoided in patients with tachycardia.

Precautions: Occasionally patients on Apresoline develop symptoms suggestive of rheumatoid arthritis. Also skin reactions and fever may occur producing a syndrome similar to systemic lupus erythematosus. This is much more likely to occur with high doses and is rare below doses of 200 mg. In cardiac failure, where higher doses may be necessary, the precautions indicated in the 'Dosage and Administration' section should be observed. If such symptoms do develop, the drug should be gradually withdrawn, when remission will usually occur. Only rarely is it necessary to treat the reaction with corticosteroids.

Apresoline should not be prescribed in cases of left ventricular heart failure due to severe aortic or mitral

stenosis or in constrictive pericarditis. Apresoline should be used with caution in patients with coronary disease or undergoing anaesthesia (which may precipitate severe hypotension), or in patients taking tricyclic antidepressants or MAO inhibitors.

Treatment of overdose: Gastric lavage or, in the absence of coma, emetic treatment should be instituted as soon as possible. If hypotension is present, an attempt should be made to raise the blood pressure without increasing the tachycardia. Adrenaline should therefore be avoided. Supportive measures such as intravenous fluids and elevation of foot of bed are also indicated. Cautious administration of angiotensin or noradrenaline intravenously may be of use.

Pharmaceutical precautions The tablets should be protected from heat and moisture.

Legal category POM.

Package quantities *Apresoline Tablets 25 mg:* Securitainers of 100.

Apresoline Tablets 50 mg: Securitainers of 100.

Apresoline Ampoules 20 mg: Dry hydralazine hydrochloride in boxes of 5.

Further information Apresoline improves the renal and uterine blood flow. This makes it ideally suited for use in toxemia of pregnancy, and in hypertension with renal complications. Apresoline also improves cerebral blood flow and is useful especially in combination with a beta-blocking drug in elderly patients.

Apresoline lowers blood pressure by a reduction in peripheral resistance, but when used as monotherapy, this beneficial effect is counterbalanced to some extent by a reflex tachycardia. The concomitant use of a beta-blocking drug like oxprenolol will prevent this associated increase in cardiac output and enhance the antihypertensive effect considerably.

DESFERAL*

Presentation A sterile, lyophilised powder available in vials containing 500 mg of desferrioxamine mesylate.

Uses A highly specific iron chelating agent recommended for the treatment of acute iron poisoning, chronic iron accumulation, primary haemochromatosis and secondary haemochromatosis (haemosiderosis); for the diagnosis of iron storage disease and certain anaemias; and for the management of corneal rust stains and ocular siderosis.

Dosage and administration When administered parenterally, the drug should be employed in the form of a 10% solution, e.g. by dissolving the contents of one vial (500 mg) in 5 ml of distilled water. If the solution is slightly opalescent, it can still safely be given intramuscularly or subcutaneously. The 10% Desferal solution can be diluted with routinely employed infusion solutions (saline, glucose, dextrose or dextrose-saline). For intravenous infusions, however, only clear solutions should be used.

The dosage recommendations are the same for adults and children.

Treatment of pathological iron overload: As a rule,

treatment with Desferal should be continued for at least several months, possibly on an intermittent basis. To assess the response, urinary iron excretion should initially be monitored daily, and later at longer intervals (but no less than once every 2 weeks).

Although Desferal can be given by intramuscular injection, in most cases it exerts a considerably greater effect when administered – preferably with the aid of a portable, light-weight, infusion pump – by continuous intravenous or subcutaneous infusion. Intravenous infusions usually prove somewhat more effective than subcutaneous infusions, which are particularly suitable for ambulant patients.

However, since the iron excretion rates obtained with the above mentioned modes of administration vary from patient to patient, one should first individually determine which of them yields the best results before embarking on long-term medication.

For the purposes of infusion treatment the average daily dose is 1.5–4 g administered intravenously or subcutaneously over a period of approximately 12 hours. In some cases it is possible to achieve a further increase in iron excretion by infusing the same daily dose over a 24-hour period.

For intramuscular treatment the average initial dose is 0.5–1 g daily, given in 1–2 injections. The maintenance dose to be selected will depend on the patient's iron excretion rate.

Treatment of acute iron poisoning: In this indication larger doses, administered both orally and parenterally are usually required. Speed is essential.

Gastric lavage should be carried out as quickly as possible using, if readily available, 1% sodium bicarbonate solution. This should be followed by the oral administration, by stomach tube if necessary, of 5–10 g (the contents of 10–20 vials) of Desferal in 50–100 ml of fluid. This will chelate any iron remaining in the stomach and prevent any further absorption.

To eliminate the iron that has already been absorbed 1–2 g Desferal should be injected intramuscularly every 3–12 hours; alternatively, Desferal should be infused either subcutaneously or – particularly if the patient is seriously ill and already in a state of shock – intravenously at a rate of not more than 15 mg/kg/h, the maximum dose in any 24 hours being 80 mg/kg. Duration of treatment will depend on the patient's condition.

Further measures, e.g. sodium bicarbonate, sedatives, oxygen, etc., may be given as necessary. The patient's progress should be checked by serum iron determinations.

It should be noted that the serum iron level may rise sharply when the iron is released from the reticuloendothelial system.

Theoretically 100 mg of Desferal can chelate approximately 8.5 mg of iron, thus 5 g can chelate the iron contained in about 10 tablets of ferrous sulphate or ferrous gluconate.

Desferal test for iron overload: This test is based on the principle that normal subjects do not excrete more than a fraction of a milligram of iron in their urine daily and a standard intramuscular injection of 500 mg of Desferal does not increase this above 1 mg. In iron storage diseases, however, the increase may be well over 1.5 mg.

Procedure:

1. The haemoglobin, serum iron and total iron binding capacity are estimated.

2. 500 mg of Desferal are given intramuscularly and 400 ml of water are drunk.

3. All urine is collected over the next six hours.
4. The urinary iron is estimated in the six hour urine specimen.

An excretion of 1–1.5 mg (18–27 μmol) of iron during this 6-hour period is suggestive of an iron-storage disease; values of more than 1.5 mg (27 μmol) can be regarded as definitely pathological. The test yields reliable results only in cases where renal function is normal.

Contra-indications, warnings, etc *Contra-indications:* None.

Precautions: Desferal should only be used with caution in patients with renal dysfunction.

In acute iron poisoning requiring treatment with Desferal in patients suffering from severe renal dysfunction, dialysis might help to eliminate the chelated iron.

Rapid intravenous injections of Desferal may give rise to hypotonic shock. This seems to be due to too rapid injection of the material. It is therefore wiser to adhere to the recommendation to give Desferal by intravenous infusion.

Where an iron-storage disease is associated with scorbutic acid deficiency, oral administration of vitamin C in the standard dosage (130–250 mg daily, given in fractional doses) may serve to enhance excretion of the iron complex in response to Desferal; larger doses of vitamin C fail to produce an additional effect. In patients with severe chronic iron-storage disease undergoing combined treatment with Desferal and high doses of vitamin C (more than 500 mg daily) impairment of cardiac function has been encountered; this proved reversible when the vitamin C was withdrawn. Monitoring of cardiac function is indicated during such combined therapy.

Pregnancy: Desferal should not be given during pregnancy unless, in the judgment of the physician, the expected benefits outweigh the potential risk.

Side-effects: There have been only rare reports of allergic skin reactions and cardiovascular (e.g. hypotension, shock), neurological (e.g. dizziness, convulsions), and gastro-intestinal disturbances, impairment of hepatic and renal function, as well as changes in the blood picture (e.g. thrombocytopenia). Some of these manifestations, however must be considered as signs and symptoms of the underlying disease. The iron complex excreted under treatment with Desferal may cause reddish-brown discoloration of the urine.

Opacities of the lens have been observed in animal experiments after prolonged administration of very high doses. Patients should therefore have their eyes examined both prior to the institution of long-term treatment with Desferal and also from time to time during medication.

Local pain may occur after intramuscular injection.

Pharmaceutical precautions Desferal should be stored at 4°C or below.

Legal category POM.

Package quantities Available in packs of 10 vials, each containing 500 mg. Desferal.

Further information Desferal is readily soluble in water so that it can be rapidly administered both orally and parenterally in situations where speed is essential. It is highly specific for trivalent iron and the resulting chelate is stable and non-toxic. The intestinal chelate is not absorbed and that formed systemically as a result of

parenteral administration is rapidly excreted via the kidneys without deleterious effects. Desferal mobilises and removes iron from all human organs, tissues and proteins excepting haemoglobin and undesirable effects on erythropoiesis have not been reported.

Method for preparing desferrioxamine eye drops:

1. **Preparation of solvent:** Formula:

Methyl cellulose 4,000 cps	25 mg	0.5%
Benzyl alcohol	50 mg	1.0%
Water for Injection q.s.	5.0 ml	100%

Method: The methyl cellulose is dispersed in water for injection at 90°C. This is cooled with continuous stirring. When the temperature reaches 35°C, benzyl alcohol is added and the solution diluted to volume with water for injection. The solution should be filtered through a No 1, then No 2 sintered glass filter. 5 ml of this solution are filled into brown/amber eye drop bottles, stoppered and autoclaved at 110°C for 20 minutes.

2. **Preparation of drops:** To be carried out under aseptic conditions.

- (a) Remove foil disc from Desferal vial containing 500 mg Desferal.
- (b) Unscrew eye drop bottle cap and take up 5 ml of solvent into a sterile syringe; replace cap.
- (c) Inject solvent into vial and shake to dissolve the Desferal. Care should be taken to dissolve all the Desferal.
- (d) Withdraw the solution into the sterile syringe; remove cap from bottle; transfer solution to bottle and replace cap.

The drops are now ready for use.

Note: Desferal (desferrioxamine mesylate) is unstable in solution and thus the eye drops should be prepared at the time of use. The solution should be discarded at the end of one week from the date of preparation.

Product licence number 0008/5073

DORIDEN*

Presentation Doriden Tablets each containing 250 mg of glutethimide as a circular, flat, white tablet with bevelled edges, having the monogram CIBA on one side and the letters GA and a break line on the other.

Uses *Mode of action:* Doriden is an effective oral, general-purpose, non-barbiturate hypnotic, with a prompt action and a medium duration of effect. The active constituent, glutethimide, is lipid soluble which ensures rapid and effective penetration of the central nervous tissue, whilst its metabolites are completely soluble in water and hence completely and easily excreted by the kidneys.

Indications: Doriden is recommended for the treatment of insomnia (including disturbed and restless sleep).

Dosage and administration *Adults:* For insomnia, initially 1 or 2 tablets a quarter to half an hour before retiring. It may be possible to reduce the dosage to 1 tablet subsequently.

Children: aged 1–6 years: $\frac{1}{2}$ tablet.

Over 6 years: 1 tablet.

Contra-indications, warnings, etc *Side-effects:* Doriden has been known occasionally to produce skin rashes, nausea and hyperexcitability, and more infre-

quently, acute hypersensitivity reactions, blood dyscrasias and peripheral neuropathy have been reported.

Prolonged use of Doriden may lead to the development of dependence and to toxic confusional states.

Contra-indications: Use in patients hypersensitive to glutethimide.

Precautions: Doriden should be used with caution in epileptic patients. Withdrawal after a prolonged period of administration in high doses or after an overdosage may lead to epileptic fits.

Doriden may cause drowsiness. Patients receiving this medication should not drive or operate machinery unless the drug has been shown not to interfere with physical or mental ability.

Doriden potentiates the effect of phenothiazines, tricyclic antidepressants, alcohol and diminishes the action of coumarin anticoagulants.

In common with all drug therapy, Doriden should not be used during pregnancy unless considered essential by the physician.

Overdosage: Mild to moderate intoxication as judged by the clinical condition of the patient, or size of the ingested dose (less than 10 g) or blood levels (less than 2.5 mg%) may be treated symptomatically. The standard measures for the care of the unconscious patient, namely gastric lavage, airway care, and the maintenance of respiration and circulation, should be instituted.

Severe intoxication where there is a deep coma, or a history of ingestion of more than 10 g or blood levels of more than 3 mg% may require haemodialysis, which should be considered early. If haemodialysis is undertaken it should be continued until the patient is awake. Careful observation for a further 24 hours is then recommended since Doriden shows affinity for body fat depots, and in response to a rapid lowering of blood levels, it may be released into the blood stream thus precipitating further coma. Sudden episodes of apnoea or hypotension have been reported, possibly related to developing cerebral oedema. Osmotic diuresis by prompt intravenous infusion of 20% mannitol solution has been shown in some cases to abort these episodes.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tablets of Doriden 250 mg in Securainers of 100 and 500.

Further information Nil.

Product licence number 0008/5005.

ESIDREX*

Presentation Tablets containing 25 mg hydrochlorothiazide, circular, flat, white, with bevelled edges, impressed with the monogram CIBA on one side and the letters CE and a break line on the other.

Tablets containing 50 mg of hydrochlorothiazide, circular, flat, white, with bevelled edges impressed with the monogram CIBA on one side and the letters UT and a break line on the other.

Uses *Mode of action:* Esidrex is a thiazide diuretic which exerts its diuretic effect in inhibiting the reabsorption of sodium, chloride and water, probably at the proximal renal tubules.

Indications: It is indicated for the treatment of oedema associated with acute and chronic heart failure, various

hepatic conditions, renal disorders; such as chronic glomerular nephritis and nephrotic syndrome, the premenstrual syndrome and fluid retention associated with obesity, diabetes insipidus or drug therapy (e.g. with corticosteroids.) It is also recommended for the treatment of hypertension, including hypertension occurring during pregnancy. It is also used to potentiate other antihypertensives such as guanethidine and reserpine.

Dosage and administration Esidrex is given orally. The dosage for adults is:

In acute and chronic heart failure – initially 50–100 mg daily, reducing to a maintenance dose of 25–50 mg three or four days weekly.

Chronic glomerular nephritis, nephrotic syndrome, ascites and hepatic cirrhosis, initially 50–75 mg daily. This may be reduced to a maintenance dose of 25–50 mg on alternate days.

Pre-menstrual oedema – 25 mg daily from the onset of symptoms until menstruation begins.

Drug-induced oedema, 25–50 mg on alternate days.

Hypertension – 25 mg increasing gradually to 75 mg daily according to the response.

Hypertension and oedema of pregnancy, mild symptoms, 25–50 mg daily, moderate hypertension – 50–100 mg daily initially and then reducing to a lower dose when control is achieved.

In all indications the total daily dose may be given as a single dose after breakfast. As Esidrex increases sodium excretion it is usually possible to relax dietary salt restrictions.

Children: At the discretion of the physician.

Contra-indications, warnings, etc

Side-effects: Side-effects such as mild anorexia, nausea, constipation and diarrhoea, skin rashes and photosensitivity may occur. There have been reports of blood dyscrasias including thrombocytopenia, but these are rare.

Contra-indications: Esidrex, in common with other thiazides is contra-indicated in the presence of precoma associated with hepatic cirrhosis, or Addison's disease or advanced renal failure.

Precautions: In patients with some degree of renal impairment, a rise in blood urea can occur and in extreme cases result in an oliguric crisis. In such cases, either the dose should be reduced or the treatment interrupted temporarily.

Prolonged doses may bring about a decrease in glucose tolerance and precipitate a diabetic condition. In known diabetics the addition of Esidrex to the treatment regime will almost certainly alter the insulin requirement.

In common with other thiazide diuretics hyperuricaemia may be induced by Esidrex. Gout may be exacerbated in patients with a previous history or family history of this condition.

Patients who are being treated with this preparation may require regular monitoring of fluid and electrolyte balance particularly when diuresis is substantial or in patients suffering from renal impairment. Potassium supplements may be required. Particular caution is needed with this preparation in the elderly since electrolyte balance is more likely to be precarious due to bowel or renal dysfunction. Also urinary retention is more likely.

Esidrex should only be used during pregnancy considered essential by the physician.

The concomitant administration of this preparation

with cardiac glycosides or hypotensive agents may necessitate adjustment of the dosage of those drugs.

Drug interactions: The action of tricyclic antidepressants and MAO inhibitors may be potentiated by Esidrex.

Overdosage: Esidrex is self-limiting in its action and toxic effects have not been observed.

Pharmaceutical precautions Esidrex should be protected from heat and moisture and should preferably be dispensed in a moisture-proof container.

Legal category POM.

Package quantities Esidrex 25 mg and 50 mg Tablets are available in Securitainers of 100 and 500.

Further information Esidrex has a powerful saluretic and diuretic action, is well tolerated and remains effective when administered for long periods.

Esidrex acts on the renal tubules, inhibiting the reabsorption of sodium and chloride. Low-salt diets may therefore be relaxed during Esidrex therapy.

Esidrex reduces high blood pressure and potentiates the action of other antihypertensives but has no effect on the blood pressure in normotensive individuals.

Esidrex Tablets 25 mg 0008/5045

Esidrex Tablets 50mg 0008/5046

SIDREX[®]-K

Description Round white, sugar-coated tablets, 2.1 mm in diameter with a maximum height of 7.7 mm. The inner, slow-release wax core contains 600 mg potassium chloride (8.06 mEq) and the outer coat contains 12.5 mg hydrochlorothiazide.

Uses *Mode of Action:* Esidrex-K is a thiazide diuretic which exerts its diuretic effect by inhibiting the reabsorption of sodium, chloride and water, probably at the proximal renal tubules.

Indications: It is indicated for the treatment of oedema associated with acute and chronic heart failure; various hepatic conditions; various renal disorders, such as chronic glomerular nephritis and nephrotic syndrome, pre-menstrual syndrome and fluid retention associated with obesity, diabetes insipidus or drug therapy (e.g. with corticosteroids). It is also recommended for the treatment of hypertension, including hypertension occurring during pregnancy. It is also used to potentiate other antihypertensives such as guanethidine and reserpine.

Dosage and administration Esidrex-K is given orally and the tablets should be swallowed whole. The dosage for adults is:

In acute and chronic heart failure – initially 50–100 mg daily (4–8 tablets), reducing to a maintenance dose of 5–50 mg (2–4 tablets) three or four days a week.

Chronic glomerular nephritis, nephrotic syndrome, cirrhosis and hepatic cirrhosis – initially 50–75 mg (4–6 tablets) daily. This may be reduced to a maintenance dose of 25–50 mg (2–4 tablets) on alternate days.

Pre-menstrual oedema: 25 mg daily from the onset of symptoms until menstruation begins.

Drug-induced oedema – 25–50 mg (2–4 tablets) on alternate days.

Hypertension – 25 mg increasing gradually to 75 mg daily according to the response.

Hypertension and oedema of pregnancy, mild symp-

oms – 25–50 mg daily (2–4 tablets), moderate hypertension – 50–100 mg (4–8 tablets), daily initially, reducing to a lower dose when control is achieved.

In all indications the total daily dose may be given as 1 dose before breakfast, or 2 equally divided doses after breakfast and lunch. As Esidrex-K increases salt excretion, it is usually possible to relax dietary salt restrictions.

Children: At the discretion of the physician.

Contra-indications, warnings, etc

Side-effects: Side-effects such as mild anorexia, nausea, constipation and diarrhoea, skin rashes and photosensitivity may occur as a result of treatment with Esidrex-K. In common with other thiazides, there have been reports of thrombocytopenia, but these are rare.

Esidrex-K tablets are designed to avoid the risks of gastro-intestinal irritation. However, if a patient under treatment with Esidrex-K develops severe vomiting, severe abdominal pains or flatulence or gastro-intestinal haemorrhage, the preparation should be withdrawn at once, because in the presence of an obstruction it could conceivably give rise to ulceration or perforation.

Contra-indications: Esidrex-K is contra-indicated in the presence of hyperkalaemia or precoma associated with hepatic cirrhosis, Addison's disease or advanced renal failure.

All solid forms of potassium medication are contra-indicated in the presence of obstructions in the digestive tract (e.g. resulting from compression of the oesophagus due to dilation of the left atrium or from stenosis of the gut).

Precautions: In patients with some degree of renal impairment, a rise in blood urea can occur and in extreme cases result in an oliguric crisis. In such cases, either the dose should be reduced or the treatment interrupted temporarily.

Prolonged doses of thiazides may bring about a decrease in glucose tolerance and precipitate a diabetic condition. In known diabetics the addition of Esidrex-K to the treatment regime will almost certainly alter the insulin requirement.

In common with other thiazide diuretics, hyperuricaemia may be induced by Esidrex-K. Gout may be exacerbated in patients with a previous history or family history of this condition.

Patients who are being treated with this preparation may require regular monitoring of fluid and electrolyte balance particularly when diuresis is substantial or in patients suffering from renal impairment. Potassium supplements may be required. Particular caution is needed with this preparation in the elderly since electrolyte balance is more likely to be precarious due to bowel or renal dysfunction. Also urinary retention is more likely.

Esidrex-K should only be used during pregnancy if considered essential by the physician.

The concomitant administration of this preparation with cardiac glycosides or hypotensive agents may necessitate adjustment of the dosage of those drugs.

Drug interactions: The action of tricyclic antidepressants and MAO inhibitors may be potentiated by Esidrex-K.

Overdosage: Esidrex-K is self-limiting in its action and toxic effects have not been observed.

Pharmaceutical precautions Esidrex-K should be protected from heat and moisture and should preferably be dispensed in a moisture-proof container.

Legal category POM.

Package quantities Esidrex-K Tablets are available in Securainers of 100 and 500.

Further information Esidrex-K has a powerful saluretic and diuretic action, is well tolerated and remains effective when administered for long periods.

Esidrex-K acts on the renal tubules inhibiting the reabsorption of sodium and chloride. Low salt diets should therefore be relaxed during Esidrex-K therapy.

Esidrex-K reduces high blood pressure and potentiates the action of other antihypertensives but has no effect on the blood pressure in normotensive individuals.

ISMELIN*

Presentation Ismelin Tablets each containing 10 mg guanethidine sulphate. Circular, flat, white tablets with bevelled edges, impressed with the monogram CIBA on one side and Ismelin 10 on the other.

Ismelin Tablets each containing 25 mg guanethidine sulphate. Circular, flat, pink tablets with bevelled edges, impressed with the monogram CIBA on one side and Ismelin 25 on the other.

Ismelin Ampoules each containing 10 mg/ml clear, colourless solution of guanethidine sulphate in a clear glass 1 ml ampoule. When Ismelin is given by intravenous infusion, the contents of the ampoule should be added to saline or dextrose saline.

Uses *Mode of action:* Ismelin is a peripheral sympathetic blocking drug which lowers blood pressure by inhibiting vasoconstrictive mechanisms.

Recommended for the treatment of all grades of hypertension. The parenteral formulation is intended for control of hypertensive crises and to obtain more rapid blood-pressure control.

Dosage and administration *Adults: oral:* Ismelin has a sustained length of action in excess of 24 hours, and can therefore be given as a single daily dose which has to be titrated to the patient's particular needs. In mild to moderate hypertension, dosage should begin at 20 mg daily, increasing if necessary to 30 mg daily. A daily dose in excess of 30 mg is rarely required in the milder grades of hypertension.

In patients with more severe hypertension, the majority will be adequately controlled and free from hypertensive symptoms on a daily dose of 40 mg or less. Occasionally, a daily dose of up to 100 mg may be required and, in exceptional cases, even more.

Increments in dosage should not exceed 10 mg and an interval of at least one week should be allowed to elapse before a further increase in dosage is introduced.

Frequent adjustment of dosage during the stabilisation period is not necessary, and according to individual assessment the interval between consultations may be up to one month.

Parenteral: In the management of hypertensive crises, including toxæmia of pregnancy, Ismelin should be given by intramuscular injection. One injection of 10–20 mg will generally cause a fall of blood pressure within 30 minutes which reaches a maximum in one to two hours and is maintained for four to six hours. If a further dose of 10–20 mg is deemed necessary, then three hours should be allowed to elapse between doses.

Children: Ismelin has been used in children, but dosage needs to be established.

Contra-indications,

Side-effects are often an exaggeration of the drug's action. By adhering to the dose and giving small increments where necessary, these effects should be avoided. Should fainting occur, the patient should be advised against rising from a sitting position, the dose should be reduced and the drug discontinued until the next visit.

If diarrhoea proves a problem, the action can be taken: (a) lower the daily dose; (b) lower the daily dose of codeine phosphate to the minimum.

Failure of ejaculation, effects on rare occasions on exertion, nasal congestion, myalgia or muscle weakness, intermittent claudication.

Toxic effects have not been reported with prolonged dosage.

Contra-indications: The drug is contraindicated in the presence of heart failure. In practice, this is rarely a problem in the treatment of hypertension by the use of Ismelin.

Precautions: Ismelin should be used with care in treating patients with renal impairment. Ismelin may increase the effect of a diuretic. As is the case with other agents, Ismelin may increase the risk of bleeding by lowering blood platelet counts or myoclonic activity.

Caution should be exercised in patients with a history of recent cerebral or myocardial infarction.

When patients have been treated with Ismelin, it should be remembered that treatment may be delayed for a day of operation. As the drug is not excreted during anaesthesia with larger doses of atropine.

N.B. Intravenous injection should be given by slow i.v. drip.

Interaction with other drugs: Ismelin, like other tricyclic antidepressants, tends to potentiate the actions of Ismelin: this is particularly true in treating patients already receiving sedatives, or those classes. The hypotensive effect is enhanced by alcohol or other depressants.

Additive effects. The tricyclic antidepressants, such as Rauwolfia alkaloids, potentiate the effects of Ismelin, bearing in mind the effects of reserpine and thiazides potentiate its action. More than normal will be required when Ismelin is given with reserpine, such as 10 mg weekly, at the same time as previous compounds.

Treatment of overdosage

tatic collapse, which usually requires no treatment other than keeping the patient recumbent. Occasionally pressor agents may be required in severe cases.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tablets 10 mg and 25 mg of smelin in bubble packs of 100 (10 modules of 10 tablets).

Also ampoules of 1 ml containing 10 mg in boxes of 1.

Further information Ismelin can be relied upon to lower blood pressure in almost all patients with hypertension. It is widely used in those patients whose blood pressure needs lowering more than can be achieved with diuretic alone. Such patients can be managed on a simple regime of two Navidrex[®] K and two Ismelin 10 mg tablets daily. Response to Ismelin is usually reliable and predictable for long periods, as tolerance requiring adjustment of dosage is not normally a problem.

smelin Ampoules 0008/5077

LIORESAL[®]

Representation Lioresal tablets each containing 10 mg aclofen; circular, flat, white tablets, uncoated, with bevelled edges, having the monogram CIBA on one side and the letters KJ and a break line on the other.

Uses Lioresal is chemically unrelated to any other antispastic agent and acts at spinal level, reducing spasticity and spasm and thereby improving the activities of daily living.

Lioresal is indicated for the relief of spasticity of voluntary muscle resulting from such disorders as: multiple sclerosis, other spinal lesions e.g. tumours of the spinal cord, syringomyelia, motor neurone disease, ankylosing myelitis, traumatic partial section of the cord.

Lioresal is also indicated in adults and children for the relief of spasticity of voluntary muscle arising from e.g. cerebrovascular accidents, cerebral palsy, meningitis, traumatic head injury.

Patient selection is important when initiating Lioresal therapy; it is likely to be of most benefit in patients whose spasticity constitutes a handicap to activities and/or physiotherapy. Treatment should not be commenced until the spastic state has become stabilized.

Dosage and administration Before starting treatment with Lioresal it is prudent to realistically assess the overall extent of clinical improvement that the patient may be expected to achieve. Careful titration of dosage is essential (particularly in the elderly) until the patient is stabilised. If too high a dosage is initiated or if dosage is increased too rapidly side-effects may occur. This is particularly relevant if the patient is ambulant, in order to minimise muscle weakness in the unaffected limbs or where spasticity is necessary for support.

Dulcis: The following gradually increasing dosage regime is suggested but should be adjusted to suit individual patient's requirements.

5 mg three times a day for three days

10 mg three times a day for three days

15 mg three times a day for three days

20 mg three times a day for three days

Satisfactory control of symptoms is usually obtained with doses up to 60 mg daily, but a careful adjustment is often necessary to meet the requirements of each individual patient. The dose may be increased slowly if required, but a maximum daily dose of more than 100 mg is not advised unless the patient is in hospital under careful medical supervision. Small frequent dosage may prove better in some cases than larger spaced doses. Also some patients benefit from the use of Lioresal only at night to counteract painful flexor spasm. Similarly a single dose given approximately 1 hour prior to the performance of specific tasks such as washing, dressing, shaving, physiotherapy, will often improve mobility.

Once the maximum recommended dose has been reached, if the therapeutic effect is not apparent within 6 weeks a decision whether to continue Lioresal should be taken.

Children: In children under eight years of age the starting dose may need to be as low as 5–10 mg daily in three or four divided doses, increasing gradually over a two week period to a maximum of 40 mg daily in divided doses. For children over eight years a starting dose of 10 mg daily in divided doses and a maximum dose of 60 mg daily are recommended.

There have been no reports of tolerance.

Contra-indications, warnings, etc Side-effects:

Nausea, vomiting, daytime sedation and confusion, as well as muscle hypotonia and fatigue, have been observed after treatment with Lioresal. The incidence of these effects may be reduced by lowering the dosage with little or no loss of therapeutic effect. Should nausea persist then it is recommended that Lioresal be ingested with food or a milk beverage.

Visual hallucinations have been reported on sudden withdrawal of Lioresal.

Precautions: Lioresal should be used with extreme care in patients already receiving antihypertensive therapy.

It should be noted that psychotic states and epileptic manifestations may be exacerbated by treatment with Lioresal.

The customary practice of avoiding drugs during the first three months of pregnancy whenever possible should also apply to Lioresal. Although Lioresal passes into breast milk, the concentrations are so low that the use of therapeutic doses should generally entail no risk for the child.

Treatment of overdose: In cases of overdose the induced hypotonia can involve the muscles of respiration. Muscular flaccidity may persist for up to three days following recovery of consciousness.

As Lioresal is principally excreted via the kidneys, it is important to maintain a high urinary output by means of an increased fluid intake and, if necessary, the use of diuretics.

There is no specific antidote to Lioresal. Symptomatic measures should be applied as required.

Pharmaceutical precautions Lioresal should be protected from heat.

Note: Details of a suitable formula for the extemporaneous preparation of a paediatric oral suspension of Lioresal are available on request to the manufacturer.

Legal category POM.

Package quantities Securitainers of 100 × 10 mg tablets of Lioresal.

Further information The major benefits of Lioresal

stem from its ability to reduce painful flexor or extensor spasms and spontaneous clonus thereby facilitating the mobility of the patient, increasing his independence and helping rehabilitation. General well being is often improved and sedation is less often a problem than with centrally acting drugs.

Product licence number 0008/0053.

LUDIOMIL*

Presentation Ludiomil tablets each containing 10 mg maprotiline hydrochloride, pale yellow, circular, film-coated tablets with CIBA on one side and the letters CO on the reverse.

Ludiomil Tablets each containing 25 mg maprotiline hydrochloride, greyish-red, circular, film-coated tablets with CIBA on one side and the letters DP on the reverse.

Ludiomil Tablets each containing 50 mg maprotiline hydrochloride; light orange, circular, film-coated tablets with CIBA on one side and the letters ER on the reverse.

Ludiomil Tablets each containing 75 mg maprotiline hydrochloride; brownish-orange, circular, film-coated tablets with CIBA on one side and the letters FS and a break line on the reverse.

Uses *Indications:* Symptoms of depressive illness.

Dosage and administration The optimum dose depends on the severity of the depression and the individual patient response to treatment. The usual dose range is 25–75 mg daily which may be given in 1 dose or in 3 divided doses.

Clinical evidence suggests that Ludiomil given once daily is effective and well tolerated, especially when given at night. Dosage at night should reduce the need for hypnotics or tranquillisers to be prescribed with Ludiomil.

Pharmacokinetic studies show that virtually the same steady-state blood levels are produced whether Ludiomil is given in once daily or divided doses.

For moderate or severe depression, treatment should start with 75 mg daily, increasing if necessary, to a maximum of 150 mg daily. Initially the patient should be closely monitored and dosage adjusted after one to two weeks according to the response. Treatment will need to be maintained until natural remission of the depression permits weaning off Ludiomil or the use of a lower dose for maintenance.

It may be advisable in elderly patients, or those who may be sensitive to this type of drug, to start treatment with lower doses such as 30 mg at night or 10 mg three times a day. This should then be adjusted in one to two weeks according to the response.

Children: Not recommended.

Contra-indications, warnings, etc *Side-effects:* Convulsions have been reported as occurring in patients both with and without a history of epilepsy.

Skin rashes are not uncommon.

Anticholinergic side-effects such as dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition have been reported less frequently with maprotiline than with standard tricyclic antidepressants.

The following adverse effects, although not necessarily all reported with Ludiomil, have occurred with tri/tetracyclic antidepressants:

Possible adverse effects include drowsiness, dizziness, sweating, postural hypotension, tremor, paraesthesia,

vivid dreams and skin rash. Interference with sexual function may occur. The incidence and severity of these side-effects does not prejudice treatment in the majority of patients.

Serious adverse effects are rare and have included depression of the bone marrow, agranulocytosis, cholestatic jaundice, hypomania.

Psychotic manifestations, including mania and paranoid delusions may be exacerbated.

Withdrawal symptoms may occur on abrupt cessation of therapy and include insomnia, irritability and excessive perspiration.

Withdrawal symptoms in neonates whose mother received tri/tetracyclic antidepressants during the third trimester have also been reported.

Contra-indications: Ludiomil is contra-indicated in severe liver or renal disease, history of epilepsy, narrow angle glaucoma, retention of urine, recent myocardial infarction.

Precautions: Do not use during pregnancy, or during lactation, especially during the first and last trimesters unless there are compelling reasons. There is no evidence as to drug safety in human pregnancy, nor is there evidence from animal work that it is free from hazard. Ludiomil is excreted in the breast milk. Nursing mother should be advised to cease breast feeding.

In common with other substances in this therapeutic group, Ludiomil should be used with caution in patient with cardiovascular disease, such as any degree of heart block or other cardiac arrhythmias.

The elderly are particularly liable to experience side effects. The initial dosage should be increased with caution under close supervision (see dosage).

Ludiomil should be administered with caution to patients with symptoms suggestive of bladder neck obstruction.

Patients posing a high suicidal risk require close initial and continuing supervision.

In common with all other substances in this therapeutic group, Ludiomil may modify patients' reactions (e.g. driving ability, operating machinery, etc.) to a varying degree, depending on dosage and individual susceptibility. Patients should be warned of this possible hazard.

Drug interactions: Ludiomil should not be given concurrently with or within 2 weeks of cessation of therapy with monoamine oxidase inhibitors.

Ludiomil may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine. It would be advisable to review all antihypertensive therapy during treatment with tri/tetracyclic antidepressants.

Ludiomil should be used with caution in patient receiving sympathomimetic agents such as ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Barbiturates may decrease whilst neuroleptics and methylphenidate may increase the plasma levels of Ludiomil.

The effects of alcohol may be potentiated by Ludiomil. Anaesthetics given during tri/tetracyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that a patient is being so treated.

Treatment of overdosage: There is no specific antidote to Ludiomil. Major signs of overdosage include convulsions and cardiovascular disturbances. The stomach should be emptied as quickly as possible by gastric lavage or emesis and unconscious patients should be

ospitalised in a unit where full support of vital functions and cardiac monitoring are possible. Treatment is symptomatic.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Ludiomil Tablets are available in our strengths, 10 mg, 25 mg and 50 mg in containers of 100 tablets, 75 mg in containers of 28 tablets. All tablets are packed in PVC/foil bubble packs.

Further information Ludiomil is a novel compound with a tetracyclic nucleus belonging to the chemical class of dibenzo-bicyclo-octadienes. It shows a broad spectrum of antidepressant activity, being highly effective in both endogenous and reactive depression. Ludiomil works quickly, some symptoms, such as insomnia, anxiety and mood, begin to improve within three to four days. This, coupled with the good tolerability of once daily dosage, makes Ludiomil a very worthwhile treatment for all forms of depression. The 75 mg tablets of Ludiomil are packed in daily reminder packs of 28 tablets, making it simple for the patient to remember to take them.

METOPIRONE*

Presentation Metopirone Capsules each containing 50 mg metyrapone in an opaque cylindrical soft gelatine capsule, coloured white.

Uses Mode of action: Metopirone inhibits the enzyme responsible for the 11 β -hydroxylation stage in the synthesis of hydrocortisone (cortisol) and to a lesser extent aldosterone.

When used as a diagnostic test of anterior pituitary function, one is relying upon its inhibiting effect on cortisol production. The consequent fall in plasma concentration of circulating glucocorticoids stimulates the anterior pituitary to produce more corticotrophin. This in turn stimulates the production of more of the precursors which are then excreted in the urine where they can be measured.

Indications: As a diagnostic aid in:

- Investigation of anterior pituitary function in hypopituitarism.
- Evaluation of the effect of prolonged corticosteroid therapy upon the hypothalamic-pituitary-adrenal axis.

or the management of patients with Cushing's syndrome.

In conjunction with glucocorticoids, in the treatment of resistant oedema due to increased aldosterone secretion in patients suffering from cirrhosis, nephrosis and congestive heart failure.

Dosage and administration *Oral dose when used as diagnostic test:* The urinary 17-oxygenic steroid excretion is determined on complete 24-hour collections for four consecutive days. The first two days serve as a control period. On the third day the subject is given by mouth a total of 6 doses, at four hourly intervals of 3 capsules (750 mg).

Children should be given a smaller amount based upon 6 four-hourly doses of 15 mg per kg, with a minimum dose of 250 mg.

For the treatment of resistant oedema 2.5 g to 4.5 g (10–18 capsules) should be given daily in divided doses.

Contra-indications, warnings, etc Side-effects: Metopirone may give rise to nausea and vomiting which can be controlled to some extent by taking a biscuit and milk at the same time as the capsule.

Note: Failure to absorb the drug due either to vomiting or malabsorption may give false results.

Precautions: Metopirone should be used with extreme caution in patients where gross hypopituitarism is suspected because of the risk of precipitating acute adrenal failure.

Because of the risk that Metopirone can impair the biosynthesis of foetal-placental steroids, it would seem unwise to administer it during pregnancy.

Treatment of Overdosage: The clinical picture of acute Metopirone poisoning is characterised by gastro-intestinal symptoms and acute adreno-cortical insufficiency. General measures should be taken to reduce the absorption and increase the elimination of the drug. A large dose of hydrocortisone should be administered, together with i.v. saline and glucose. This should be repeated as necessary in accordance with the patient's clinical condition.

Pharmaceutical precautions The capsules should be protected from heat and moisture.

Legal category POM.

Package quantities 250 mg capsules of Metopirone in Securitainers of 100.

Further information Since the response to Metopirone involves the adrenal cortex, it is necessary to ensure that the adrenal function is adequate (by means of ACTH or 'Synacthen') before ascribing a subnormal response to hypothalamic or pituitary dysfunction. It must be emphasised that this procedure assesses only the feedback control mechanism, and a normal response does not necessarily indicate the ability of the HPA axis to respond to stress.

Product licence number 0008/5078

MONASPOR* ▼

Presentation Vials containing dry active substance corresponding to 0.5 g and 1 g cefsulodin sodium for intramuscular and intravenous use.

Uses Mode of action: Monaspor is a semi-synthetic bactericidal beta-lactam antibiotic for parenteral use which displays marked activity against *Pseudomonas aeruginosa*. The minimum inhibitory concentrations (MIC) are very low, lying within the range of 0.25–8 mcg/ml for 88% of the *Pseudomonas* strains investigated.

Monaspor is stable against the majority of relevant beta-lactamases and is also active against most strains of *Pseudomonas aeruginosa* resistant to carbenicillin and gentamicin.

Indications: Monaspor is indicated for the treatment of infections caused by sensitive strains of *Pseudomonas aeruginosa*. These include:

Chronic recurrent urinary tract infections e.g. pyelo-

nephritis, infections accompanying obstructions of the urinary tract (e.g. in the presence of neoplasms; calculi of the urinary tract, or following surgery), prostatitis.

Respiratory tract infections e.g. pneumonia, chronic purulent bronchitis and infections associated with mucoviscidosis.

A number of cases of *Pseudomonas* infection of bone and soft tissue, such as osteomyelitis, and infected wounds and burns have been treated successfully with Monaspor.

Dosage and administration *Adults:* In adults with normal renal function the usual daily dose is 1–4 grams daily in 2–4 fractional doses.

In urinary tract infections, and chronic bronchitis, 1–3 grams daily in 2–4 fractional doses usually suffices.

In critical cases (e.g. severe pneumonia, osteomyelitis) daily doses of 6 grams or more may be necessary.

Children: The recommended daily dose is 20–50 mg/kg bodyweight.

Administration: Intramuscular: The dry powder should be dissolved using the accompanying 0.5% lignocaine solution before intramuscular administration.

Intravenous: The dry powder should be reconstituted with Water for Injection to a concentration of 1 g in 10 ml and slowly injected either directly into a vein or into the tube of an intravenous drip.

Infusion: Monaspor can be dissolved in the routinely employed solutions e.g. Sodium Chloride Intravenous Infusion BP, Ringer's Injection USP, Dextrose Intravenous Infusion BP, Dextran 40 Intravenous Infusion BP (10%). It must not be mixed with sodium bicarbonate.

When administering an infusion lasting more than 30–60 minutes and in order to obtain high initial blood levels, it is advisable to inject the first dose as a slow bolus injection.

If Monaspor is infused intermittently via a Y-attachment to another infusion, administration of the latter should be interrupted while the Monaspor infusion is in progress.

Monaspor can be administered in combination with other antibiotics such as gentamicin or carbenicillin. They can either be infused together or injected in the same syringe (diluted with Water for Injection to a total volume of 10 ml). Monaspor, however, should not be pre-mixed with tobramycin but they may be administered separately.

Aqueous solutions of the drug take on a yellow colouration. This has no effect on the drug's antibiotic activity.

Solutions displaying clouding or precipitation after admixing of the drug should not be used.

Only freshly prepared Monaspor solutions should be employed. Monaspor infusion solutions should not be used if they have been stored for longer than 24 hours in a refrigerator (5°C) or 12 hours at room temperature (23°C). Mixtures containing Monaspor and other drugs in the same syringe should not be stored for more than 4 hours at room temperature. The stability of Monaspor solutions is greatest between pH 4–7. Solutions with a pH of greater than 7 should be administered immediately after they have been prepared.

Contra-indications, warnings, etc *Contra-indications:* Hypersensitivity to cephalosporins.

Precautions: In chronic infections it is important that the treatment should be of sufficiently long duration to obtain a successful clinical result.

In cases where lengthy treatment with large doses of

Monaspor is required, blood counts and tests of renal function should be performed.

As with any type of antibiotic therapy, it is advisable to determine the sensitivity of the causative micro-organisms before initiating treatment.

In patients known to be allergic to penicillin, caution should be exercised when employing Monaspor, since cross-sensitivity with cephalosporins may be encountered. If allergic reactions occur, Monaspor should be withdrawn and suitable countermeasures taken.

In patients with renal failure, the priming dose should be the same as in patients without renal disease. Repeat doses, however, must be reduced in size or the interval between them prolonged. The recommendations in the following table may be used as a guide. The elimination of the drug in dialysis fluid is about 45% of the dose and it is suggested that a normal dose be given at the beginning and end of the dialysis period.

<i>Creatinine clearance</i>	<i>Maintenance doses in % of normal doses at following intervals:</i>			
<i>ml/min</i>	<i>6 h</i>	<i>8 h</i>	<i>12 h</i>	<i>24 h</i>
50	90	90	95	—
30	75	80	90	—
20	65	70	80	—
10	55	60	70	—
5	45	55	65	—
2.5	40	45	60	—
0	—	—	—	75

In patients suffering from severe liver damage and in those allergic to local anaesthetics, Monaspor should be given intramuscularly with sterile Water for Injection or intravenously (i.e. without lignocaine).

When determining urinary sugar levels, enzymatic methods should be used because other techniques may yield false positive results.

Pregnancy: As with other drugs, the use of Monaspor during pregnancy is advised only if there are compelling reasons.

Side-effects: Monaspor is generally well tolerated. The following have been observed as rare side effects: nausea, dizziness, allergic skin reactions, and eosinophilia, as well as occasional increases in the values for transaminases, alkaline phosphatase, non-protein nitrogen, and serum creatinine. Intravenous injections of Monaspor are usually painless when administered slowly. Local pain occurring as a reaction to intramuscular injections can be prevented by employing the accompanying ampoules of 0.5% lignocaine solution.

Pharmaceutical precautions The vials should be stored below 25°C and protected from light.

Legal category POM.

Package quantities *For intramuscular injection:* Vial containing 0.5 g or 1 g of active substance with ampoule of 0.5% lignocaine solution (3 ml).

For intravenous injection: Vials containing 0.5 g or 1 g of active substance.

Further information Nil.

Product licence numbers

1 g vials for intravenous injection	0008/0162

NAVIDREX®

Presentation Navidrex Tablets containing 0.5 mg of cyclopenthiiazide as white, flat, circular tablets with bevelled edges, bearing the monogram CIBA on one side, and the letters AO on each side of a breakline on the other.

Uses *Mode of action:* Navidrex is a thiazide diuretic which exerts its diuretic effect by inhibiting the reabsorption of sodium, chloride and water, probably at the proximal renal tubules.

Indications: Navidrex is indicated for the treatment of mild to moderate hypertension, in more severe hypertension it may be used in conjunction with other anti-hypertensive agents. It is also indicated for the treatment of acute and chronic heart failure, cardiac asthma, oedema associated with renal disease, pre-menstrual tension, liver disease, drug therapy and obesity, oedema and hypertension associated with pregnancy.

Dosage and administration *Adults:* Hypertension 0.25 mg to 0.5 mg daily, increasing rarely to a maximum of 1.5 mg. For best results in hypertension doses should be given seven days a week, the entire dose being taken in the morning.

In acute and chronic heart failure, cardiac asthma, oedema associated with renal or liver disease, obesity, or drug induced oedema, an initial dose of 0.5 mg to 1 mg until a satisfactory clinical response is attained. The maximum effective dose is 1.5 mg daily although this is rarely required. When a satisfactory clinical response is achieved a dose of 0.5 mg on alternate days is usually adequate.

Pre-menstrual tension 0.25 mg to 0.5 mg daily from the onset of symptoms until menstruation begins.

Since Navidrex increases salt excretion it is usually possible to relax dietary salt restriction.

Contra-indications, warnings, etc *Side-effects:* Side-effects such as mild anorexia, nausea, constipation and diarrhoea, skin rashes and photosensitivity may occur. There have been reports of blood dyscrasias including thrombocytopenia, but these are rare.

Contra-indications: Navidrex is contra-indicated in the presence of precoma associated with hepatic cirrhosis or Addison's disease or advanced renal failure.

Precautions: In patients with some degree of renal impairment, a rise in blood urea can occur and in extreme cases result in an oliguric crisis. In such cases, either the dose should be reduced or the treatment interrupted temporarily.

Prolonged doses may bring about a decrease in glucose tolerance and precipitate a diabetic condition. In known diabetics the addition of Navidrex to the treatment regime will almost certainly alter the insulin requirement.

In common with other thiazide diuretics hyperuricaemia may be induced by Navidrex. Gout may be exacerbated in patients with a previous history or family history of this condition.

Patients who are being treated with this preparation may require regular monitoring of fluid and electrolyte balance particularly when diuresis is substantial or in patients suffering from renal impairment. Potassium supplements may be required. Particular caution is needed with this preparation in the elderly since electrolyte balance is more likely to be precarious due to bowel or renal dysfunction. Also urinary retention is more likely.

Navidrex should only be used during pregnancy if considered essential by the physician.

The concomitant administration of this preparation with cardiac glycosides or hypotensive agents may necessitate adjustment of the dosage of those drugs.

Pharmaceutical precautions Usual storage precautions apply.

Legal category POM.

Package quantities Navidrex is available in Securitainers of 100 and 500.

Further information After a single oral dose diuresis starts within one or two hours reaching a maximum in four to eight hours, lasting up to 12 hours. If taken in the morning the clearly defined duration of action ensures that the patient can sleep undisturbed at night. It is important that the patient be encouraged to take a potassium rich diet during treatment with Navidrex. For routine use, it is advisable to give supplementary potassium, e.g. 'Slow-K' or alternatively to use 'Navidrex-K' which contains 'Slow-K'.

Product licence number 0008/5047.

NAVIDREX-K®

Presentation Yellow-ochre, polished, sugar coated tablets, about 12 mm in diameter, having an inner slow-release wax core containing Potassium Chloride BP 600 mg (8.06 mEq) and an outer coat containing 0.25 mg cyclopenthiiazide.

Uses Navidrex-K is a thiazide diuretic, which exerts its diuretic effect by inhibiting the reabsorption of sodium, chloride and water, probably at the proximal renal tubules. It is indicated for the treatment of mild to moderate hypertension. In more severe hypertension it may be used in conjunction with other antihypertensive agents. Navidrex-K is also indicated for the treatment of acute and chronic heart failure, cardiac asthma, oedema associated with renal disease, pre-menstrual tension, liver disease, drug therapy and obesity, oedema and hypertension associated with pregnancy.

Dosage and administration *Adults: Oral:* In hypertension, 0.25–0.5 mg (1 or 2 tablets) daily is usually sufficient. Rarely, 1.5 mg (6 tablets) daily may be required. For best results in hypertension doses should be given seven days a week. In acute and chronic heart failure, cardiac asthma, oedema associated with renal or liver disease and oedema associated with obesity or drug-induced oedema, an initial dose of 0.5–1 mg (2–4 tablets) daily until a satisfactory clinical response is attained.

The maximum effective dose is 1.5 mg (6 tablets) daily, although this is rarely required.

When a satisfactory clinical response is achieved, a maintenance dose of 0.25–0.5 mg (1 or 2 tablets) daily or 0.5 mg (2 tablets) on alternate days is usually adequate.

Pre-menstrual tension, 0.25–0.5 mg (1 or 2 tablets) daily from the onset of symptoms until menstruation begins.

The entire daily dose should be taken in the morning and it is important that the tablet be swallowed whole.

Children: Oral: At the discretion of the physician.

Note: Since Navidrex-K increases salt excretion it is usually possible to relax dietary salt restrictions.

Contra-indications, warnings, etc *Side-effects:* Side-effects such as mild anorexia, nausea, constipation and diarrhoea, skin rashes and photosensitivity may occur as a result of treatment with Navidrex-K. In common with other thiazides, there have been reports of thrombocytopenia, but these are rare.

Navidrex-K tablets are designed to avoid the risks of gastro-intestinal irritation. However, if a patient under treatment with Navidrex-K develops severe vomiting, severe abdominal pains or flatulence or gastro-intestinal haemorrhage, the preparation should be withdrawn at once, because in the presence of an obstruction it could conceivably give rise to ulceration or perforation.

Contra-indications: Navidrex-K is contra-indicated in the presence of hyperkalaemia or precoma associated with hepatic cirrhosis, Addison's disease or advanced renal failure.

All solid forms of potassium medication are contra-indicated in the presence of obstructions in the digestive tract (e.g. resulting from compression of the oesophagus due to dilation of the left atrium or from stenosis of the gut).

Precautions: In patients with some degree of renal impairment, a rise in blood urea can occur and in extreme cases result in an oliguric crisis. In such cases, either the dose should be reduced or the treatment interrupted temporarily.

Prolonged doses of thiazides may bring about a decrease in glucose tolerance and precipitate a diabetic condition. In known diabetics the addition of Navidrex-K to the treatment regime will almost certainly alter the insulin requirement.

In common with other thiazide diuretics, Navidrex-K may precipitate an attack of gout in patients predisposed to this condition.

Patients who are being treated with this preparation may require regular monitoring of fluid and electrolyte balance particularly when diuresis is substantial or in patients suffering from renal impairment. Potassium supplements may be required. Particular caution is needed with this preparation in the elderly since electrolyte balance is more likely to be precarious due to bowel or renal dysfunction. Also urinary retention is more likely.

Navidrex-K should only be used during pregnancy if considered essential by the physician.

The concomitant administration of this preparation with cardiac glycosides or hypotensive agents may necessitate adjustment of the dosage of those drugs.

Pharmaceutical precautions Navidrex-K Tablets should be protected from heat and moisture. The tablets should be dispensed in a moisture-proof container.

Legal category POM.

Package quantities Navidrex-K Tablets are available in Securitainers of 100 and 500.

Further information The low absolute doses required with Navidrex-K, compared to other thiazide diuretics, make it economical in all appropriate indications. After a single dose, diuresis starts within 1–2 hours, reaches a maximum in 4–8 hours and lasts about 12 hours. Thus a morning dose will permit the patient to sleep undisturbed at night. Hypertension is also controlled by a single daily dose. The built-in potassium supplement is based on

Slow-K* and compared with other potassium supplements, is less likely to produce an unpalatable taste, gastro-intestinal irritation or inadequate absorption.

Product licence number 0008/5036.

ORIMETEN* ▼

Presentation White to yellowish white tablets, round with slightly convex faces and slightly bevelled edges, printed with 'CIBA' on one side, and 'GG' with score on the other side. Each tablet contains 250 mg aminogluthetimide.

Uses *Mode of action:* Orimeten inhibits steroid biosynthesis in the adrenal cortex, thereby producing a medical adrenalectomy. This inhibition occurs at a very early stage, i.e. the conversion of cholesterol to Δ^5 pregnenolone. Suppression of oestrogen production in peripheral tissue may also play a part in the response to Orimeten in patients with carcinoma of the breast.

Indications: Metastatic carcinoma of the breast in post-menopausal or oophorectomised women (especially where the tumours are oestrogen-sensitive), including in particular patients in whom adrenalectomy or hypophysectomy would otherwise be indicated.

In many cases, metastases or recurring tumours diminish in size or even disappear during treatment with Orimeten. Such remission may be maintained for several years. Bone metastases attributable to breast cancer respond particularly well, the patient often experiencing marked relief of pain.

Dosage and administration Treatment should commence at 250 mg twice daily for 2 weeks. In the absence of severe unwanted effects, the dose may then be increased to 250 mg four times daily. Doses greater than 1 g daily should be avoided as side effects may occur more frequently.

Supplementary therapy: In addition to its effect on oestrogen synthesis, Orimeten suppresses the production of glucocorticoids, and in patients with carcinoma of the breast supplementary glucocorticoids will be needed (e.g. 20 mg hydrocortisone b.d.). It should be noted that Orimeten accelerates the metabolism of dexamethasone, hence if this glucocorticoid is used, a relatively high dose (up to 3 mg daily) is required.

In some patients the suppression of aldosterone synthesis may lead to hyponatraemia, hyperkalaemia, hypotension and dizziness, in which case a mineralocorticoid (e.g. fludrocortisone 0.1–0.15 mg daily or on alternate days) should be given.

Contra-indications, warnings, etc

Precautions: The patients blood count and plasma electrolytes should be checked regularly. Occasionally, Orimeten has been found to diminish thyroid function. If, during treatment for carcinoma of the breast signs of Cushing's Syndrome (due to concomitant glucocorticoid medication) appear, the dosage of the glucocorticoid should be reduced.

Orimeten may increase the rate of metabolism of some drugs, e.g. coumarin anti-coagulants, oral anti-diabetic agents, dexamethasone, whose dosage may need to be adjusted.

Use in pregnancy: Since foetal abnormalities have been observed in animals and there have been cases of pseudohermaphroditism in newborn infants of women treated with Orimeten, use during pregnancy and lactation is contra-indicated.

Side-effects: The tolerability of Orimeten varies greatly from patient to patient. Central nervous side effects, such as dizziness, somnolence and lethargy, are relatively common and dose dependent; unsteadiness occurs only in the higher dosage range. Gastrointestinal effects such as nausea, vomiting or diarrhoea, are less frequent and likewise dose-dependent. Drug rash – accompanied sometimes by fever – may develop after 7–14 days; it usually subsides within 7–10 days despite continued treatment, but if it fails to do so, the treatment must be reduced or temporarily withdrawn or the dosage of the corticosteroid raised. There have been rare reports of pancytopenia, leucopenia and agranulocytosis.

Accidental overdosage: No serious outcome following overdosage of aminogluthethimide has been reported. However, gastric lavage will be useful when indicated, together with full supportive measures to maintain respiration and circulation in the unconscious patient. In severe cases, haemodialysis or charcoal haemoperfusion may aid removal of the drug. In all cases steroid replacement must be maintained.

Pharmaceutical precautions Protect from heat, light and moisture.

Legal category POM.

Package quantities Securitainers of 100 tablets.

Further information Medical adrenalectomy with Orimeten carries significant advantages over surgical adrenalectomy. Corticosteroid secretion is inhibited in a reversible and controllable manner with none of the risks associated with surgery.

Product licence number 0008/0147

OTRIVINE* NASAL DROPS OTRIVINE* NASAL SPRAY OTRIVINE* NASAL DROPS PAEDIATRIC

Presentation Clear, colourless, odourless solutions. Otrivine Nasal Drops and Spray contain 0.1% w/v xylometazoline hydrochloride. Otrivine Nasal Drops Paediatric contain 0.05% w/v xylometazoline hydrochloride.

Uses Otrivine has a local vasoconstrictor action producing relief of nasal congestion lasting for up to 12 hours. It is indicated in the treatment of nasal congestion, perennial and allergic rhinitis, including hay fever and sinusitis.

Dosage and administration Since Otrivine clears nasal congestion in a few minutes and the effect persists for up to 12 hours, it is only necessary to administer the drops or spray twice, or at the most, three times, a day. Patients may prefer one application at night to ensure a clear nasal airway and avoid sleep disturbance.

Adults: 2 or 3 drops of the 0.1% solution or one or two applications of spray in each nostril, two or three times daily.

N.B. The 0.1% solution should not be used for children under the age of 12 years.

Infants and children under 12: 1 or 2 drops of Otrivine Paediatric Solution 0.05% once or twice daily for average cases. The specially designed paediatric dropper bottle limits the volume of each application to prevent accidental overdosage. Otrivine Paediatric Solution can be used in infants where nasal congestion is interfering with feeding.

Contra-indications, warnings, etc *Side-effects:* Side-effects are infrequent with Otrivine and are generally mild, but may include local stinging and discomfort, sneezing, dryness of the nose, headache, insomnia, drowsiness or palpitations.

Precautions: The prolonged use of vasoconstrictors is not recommended in chronic rhinitis. It should be noted that excessive use or abuse of Otrivine may cause rebound congestion or drug-induced rhinitis.

Treatment of overdosage: Treatment will only be necessary in infants and young children when they could be expected to fall into a deep sleep followed by recovery within 12 hours. In addition to gastric lavage symptomatic treatment of convulsions or respiratory depression should be given if these arise.

Pharmaceutical precautions None.

Legal category P.

Package quantities Otrivine 0.1% Nasal Spray and Drops 10 ml. Otrivine 0.05% Nasal Drops Paediatric 10 ml.

Further information Otrivine has been shown to provide much more prolonged relief from nasal congestion than ephedrine. In contrast to the effect of the latter, the vasoconstrictor action is not intense, therefore decongestion is achieved without local discomfort and rebound nasal congestion is unlikely to occur.

OTRIVINE*-ANTISTIN* NASAL DROPS OTRIVINE*-ANTISTIN* NASAL SPRAY

Presentation A clear, colourless, odourless solution containing xylometazoline hydrochloride 0.05% w/v antazoline sulphate 0.5% w/v.

Uses Otrivine-Antistin is a combined long-acting vasoconstrictor and antihistamine for the prompt relief of rhinitis associated with seasonal or perennial allergies, such as hay fever.

Dosage and administration For local administration to the nose.

Adults: Nasal spray or drops, one application from the spray or two or three drops applied to each nostril two or three times daily. One application at bedtime if necessary.

Contra-indications, warnings, etc *Side effects:* Side effects are infrequent with Otrivine-Antistin and are generally mild. They may include local stinging and discomfort, sneezing, dryness of the nose, headache, insomnia, drowsiness or in sensitive patients tachycardia. Prolonged use of Otrivine-Antistin may cause rebound congestion and drug-induced rhinitis.

Precautions: The prolonged use of vasoconstrictors is not recommended in chronic rhinitis. Antihistamines may cause drowsiness, if affected do not drive or operate machinery. Avoid alcoholic drink.

Contra-indications: Nil.

Pharmaceutical precautions The preparation should be protected from heat.

Legal category P.

Package quantities

Nasal Spray 10 ml.

Nasal dropper bottle 10 ml.

Further information Otrivine-Antistin is a gentle, long-acting combination, which, used in accordance with the recommended dosage, is free from rebound effects.

Otrivine-Antistin Nasal Spray 0008/5117

RIMACTANE*

Presentation Rimactane Capsules each containing 150 mg rifampicin. An opaque, two-piece, hard gelatine capsule size 2, reddish-brown in colour, marked with the monogram CIBA on each half and the code JZ 150. The capsule has a diameter of 6.2 mm approx. and is 17.8 mm approx. in length.

Rimactane Capsules each containing 300 mg rifampicin. An opaque, two-piece, hard gelatine capsule size 1, coloured reddish-brown and dark brown, marked with the monogram CIBA on each half and the code CS 300. The capsule is approx. 6.8 mm in diameter and 18.7 mm approx. in length.

Rimactane Syrup: An opaque, red-coloured suspension having the odour and taste of raspberry; each 5 ml contains 100 mg rifampicin.

Uses *Mode of action:* Rimactane is a semi-synthetic antibiotic with bactericidal activity against most groups of mycobacteria.

Indications: Rimactane is a major drug in the management of tuberculosis and certain opportunist mycobacterial infections. It is effective in cases resistant to other anti-tuberculous agents and shows no cross-resistance outside the rifamycin group of drugs. It is effective in combination with isoniazid, streptomycin, pyrazinamide, ethambutol and the majority of second-line drugs.

Dosage and administration Rimactane should be given as a single dose, preferably on an empty stomach, at least 30 minutes before breakfast to ensure a high peak serum concentration. Dosage should be adjusted according to body weight of patients.

Adults: Oral: 450–600 mg daily as a single dose (based on approximately 10 mg per kg body weight). (Those patients 50 kg (8 stone) and over should take 600 mg rifampicin daily, whilst patients under 50 kg should take 450 mg).

Children: Oral: Up to 20 mg per kg body weight daily to a maximum of 600 mg as a single dose.

Premature and newborn infants: Oral: 10 mg/kg once daily. Do not exceed this dosage. These infants, in whom the liver enzyme system is not yet fully developed, should be given Rimactane only in grave emergencies.

Rimactane must always be given in association with at least one and preferably two other anti-tuberculosis drugs, to prevent the emergence of resistant strains. Especially good results have been reported when Rimactane has been used in combination with isoniazid and ethambutol. Whilst it is not generally recommended that rifampicin be used in combination with PAS, if for any reason this regimen is used, the drugs should be given not less than eight hours apart to ensure satisfactory blood levels.

Use in pregnancy and lactation: Rifampicin has been

shown to have teratogenic effects in animals on very high doses, therefore during pregnancy the use of Rimactane should, if possible, be avoided. Particularly during the first 3 months of pregnancy, the drug's possible risks for the foetus must be carefully weighed against its therapeutic benefits for the mother.

When administered during the last few weeks of pregnancy, Rimactane can cause post-natal haemorrhages in mother and infant, for which treatment with vitamin K may be indicated.

Rifampicin is excreted in breast milk. Mothers in whom its use proves unavoidable should refrain from breast-feeding their infants.

Contra-indications, warnings, etc. *Contra-indications:* Rimactane is contra-indicated in patients with jaundice or where there is known hypersensitivity to rifamycins.

Precautions: As Rimactane is excreted principally by the biliary tract, caution should be exercised in treating patients with hepatic disorders. Such patients should have liver function monitored during treatment.

In the presence of complete renal failure rifampicin is excreted entirely in the bile, provided hepatic function is not impaired the dosage of rifampicin need not be adjusted.

The occurrence of liver function abnormalities is more common when rifampicin and isoniazid are used in combination, special care is therefore required in patients with pre-existing liver impairment, or in the elderly, malnourished or very young patient.

When resuming treatment with Rimactane after a temporary or a prolonged interval, the drug should be given in small, gradually increasing doses. In adults an initial dose of 75 mg daily should be administered raised subsequently by 75 mg per day until the desired dosage level is attained. If, as may happen in exceptional cases the patient develops renal failure, thrombocytopenia, purpura or haemolytic anaemia, treatment with Rimactane should be stopped at once and not re-instituted at a later date.

Microbiological techniques for assaying the serum concentrations of folic acid and vitamin B₁₂ are not suitable for use during treatment with rifampicin.

Drug interactions: Rifampicin is a potent inducer of liver enzymes which may increase the metabolism of concomitantly administered drugs such as corticosteroids, oral contraceptives, oral anti-coagulants, oral anti-diabetic agents, dapsone, phenytoin, some digitalis preparations, quinidine and methadone. The dosage of these drugs may need considerable review when Rimactane is being prescribed, larger doses usually being needed when Rimactane is introduced and a reduction on withdrawal.

In women receiving treatment with rifampicin it has been found that the contraceptive activity of oral contraceptives may be impaired. In such cases, additional non-hormonal methods should be employed.

Side-effects: Occasionally, gastrointestinal disturbances and skin rashes have been reported after treatment with Rimactane.

Side-effects to rifampicin, probably of immunological/allergic origin have been reported, particularly in connection with intermittent, interrupted or repeated treatment; e.g. influenza-like symptoms and rarely skin rashes, fever and dyspnoea have occurred. If serious complications arise such as thrombocytopenia, purpura, renal failure or haemolytic anaemia, rifampicin should be stopped at once and never restarted.

There may be an elevation of serum bilirubin levels, SGOT and SGPT levels and more rarely alkaline phosphatase during the early stages of treatment. In patients with previously normal liver function these changes are transient and usually revert towards normal pre-treatment levels in about two weeks even when Rimactane is continued. Routine liver function tests during treatment are unnecessary unless the patient becomes unwell or exhibits frank jaundice. The occurrence of jaundice may call for temporary cessation of treatment however in most patients it is possible to resume therapy. (See Precautions).

In common with other antibiotics, mild leucopenia and eosinophilia have been reported in a few patients, but appear to be of no particular clinical significance and no causal relationship has been established.

Treatment of overdosage: There is no specific antidote to Rimactane. In cases of severe overdosage gastric lavage may be undertaken and general supportive treatment administered.

Pharmaceutical precautions This product should be protected from heat and moisture.

The syrup to be stored below 25°C. Both capsules and syrup have a shelf-life of four years.

Legal category POM.

Package quantities Capsules of 150 mg Rimactane (red) and 300 mg Rimactane (red and brown) in securitainers of 100.

Syrup containing 100 mg in 5 ml; in bottles of 100 ml.

Further information Rimactane is orally active, very well tolerated and its activity is comparable with that of isoniazid. In combination, these two agents are commonly used as first-line therapy and offer the greatest chance of rapid eradication of the infection. It is usual, however, to employ a third drug during the first two months of treatment or at least until the results of sensitivity tests are known. The orange-red colour imparted to the urine, sputum and tears by rifampicin is a valuable guide to adherence to the drug regime. Rifampicin may also permanently discolour soft contact lenses.

RIMACTANE* INFUSION

Presentation 10 ml vial containing 300 mg rifampicin (red lyophilised powder) with an accompanying 5 ml ampoule of clear colourless solvent solution (Water for Injection BP + polysorbate 81).

20 ml vial containing 600 mg rifampicin (red lyophilised powder) with an accompanying 10 ml ampoule of clear colourless solvent solution (Water for Injection BP + polysorbate 81).

Uses Rimactane Infusion is indicated in patients with all forms of tuberculosis who are unable to tolerate oral therapy, e.g. post operative or comatose patients or patients in whom gastro-intestinal absorption is impaired.

Dosage and administration *Treatment of tuberculosis* with Rimactane Infusion should concurrently include the use of other effective anti-tuberculous drugs to prevent the emergence of rifampicin-resistant strains of Mycobacteria.

Adults: In tuberculosis daily administration of 600 mg when given in an intravenous drip over two to three hours has been found to be effective and well tolerated for the majority of adult patients. Serum concentrations following this dosage regimen are similar to those obtained after 600 mg by mouth. Lower doses are recommended for small, or frail and elderly patients. A daily dose of 8 mg/kg bodyweight should not be exceeded in patients with impaired liver function.

Transfer to oral therapy: When patients are able to accept oral medication, they should be transferred to Rimactane capsules or syrup. Oral dosage would be expected to be the same as that used with the infusion (see oral Rimactane data sheet).

Children: Paediatric usage has not yet been established. However, the following regimens are suggested:

In tuberculosis, a single daily dose of up to 20 mg/kg bodyweight is recommended, although total daily dose should not usually exceed 600 mg.

Preparation of Infusion: Rimactane Infusion is prepared for use by aseptically adding the solvent to the vial of rifampicin powder and shaking vigorously and continuously for about 30 seconds.

When the powder has completely dissolved, the solution should be immediately diluted in 500 ml (600 mg of rifampicin) or 250 ml (300 mg of rifampicin) of 5% glucose solution or other suitable infusion fluid (see Pharmaceutical Precautions). It is suggested that the infusion is administered over a period of 2-3 hours. The preparation should be used within 6 hours.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to rifamycins.

Although not recommended for use in patients with jaundice, the therapeutic benefit of Rimactane Infusion should be weighed against the possible risks.

During pregnancy the use of Rimactane should if possible be avoided. Particularly during the first 3 months of pregnancy the drug's possible risks for the foetus must be carefully weighed against its therapeutic benefits for the mother.

When administered during the last few weeks of pregnancy, Rimactane can cause post-natal haemorrhages in the mother and infant, for which treatment with vitamin K may be indicated.

Rimactane passes into the breast milk. Mothers in whom its use proves unavoidable should refrain from breast-feeding their infants.

Precautions: As rifampicin is excreted principally by the biliary tract, caution should be exercised in treating patients with hepatic disorders. Such patients should have liver function monitored during treatment and lower doses of Rimactane Infusion may be necessary.

The occurrence of liver function abnormalities is more common when rifampicin and isoniazid are used in combination and special care is therefore required when these are used in patients with pre-existing liver impairment or in the elderly, malnourished or very young patients.

Rifampicin is a potent inducer of liver enzymes which may increase the metabolism of concomitantly administered drugs such as corticosteroids, oral contraceptives, oral anticoagulants, oral antidiabetic agents, dapsone, digitalis preparations, quinidine, and methadone. The dosage of these drugs may need considerable review when rifampicin is being prescribed, larger doses usually being needed when rifampicin is introduced and a reduction when it is withdrawn.

Women taking oral contraceptives should use additional non-hormonal means of contraception.

When resuming treatment with rifampicin after a prolonged interval, renal function should be closely monitored. If, as may happen in exceptional cases, the patient develops renal failure, thrombocytopenia, purpura, or haemolytic anaemia, treatment with rifampicin should be stopped at once and not re-instituted at a later date.

Notes: In the presence of complete renal failure, rifampicin is excreted entirely in the bile; provided hepatic function is not impaired the dosage of rifampicin need not be adjusted.

Microbiological techniques for assaying the serum concentrations of folic acid and Vitamin B₁₂ are not suitable for use during treatment with rifampicin.

Side-effects: Rimactane Infusion is generally very well tolerated and accepted by patients, although hypersensitivity reactions have been described, and occasionally patients have experienced fever, skin rashes and nausea/vomiting. A few cases of broncho-spasm, occurring mainly in chronic asthmatics, have been reported; no causal relationship has been established.

Local tolerability: occasional instances of phlebitis and pain at the infusion site have been reported.

Side-effects to rifampicin, probably of immunological/allergic origin have been reported, particularly in connection with intermittent, interrupted or repeated treatment; for example, influenza-like symptoms, and, rarely skin rashes, fever and dyspnoea have occurred. If serious complications arise such as thrombocytopaenia, purpura, renal failure or haemolytic anaemia, rifampicin should be stopped at once and never restarted.

In patients with previously normal liver function, experience has shown that in many cases changes in liver function are transient and usually revert towards normal pre-treatment levels in about two weeks, even when rifampicin is continued. Routine liver function tests during treatment are unnecessary unless the patient becomes unwell or exhibits frank jaundice. An isolated report showing a moderate rise in the serum bilirubin and/or transaminase or more rarely alkaline phosphatase level is not usually itself an indication for interrupting treatment. The decision should be made after repeating the tests, noting the trends in the levels and considering them in conjunction with the patient's clinical condition. It has been possible in most patients in whom alterations to liver function caused interruption of Rimactane Infusion therapy, to carefully reinstate the drug.

In common with other antibiotics, mild leucopenia, and eosinophilia have been reported in a few patients, but appear to be of no particular clinical significance and no causal relationship has been established.

Rifampicin may produce a reddish discolouration of the urine, sputum and tears; soft contact lenses may also be discoloured.

Pharmaceutical precautions Rimactane Infusion should be freshly prepared. Rifampicin powder and the solvent as supplied have a shelf life of 3 years when stored at room temperature.

Compatibility: Rimactane Infusion is compatible with the following infusion solutions for up to 6 hours: Mannitol 10% and 20%. Macrodex with saline solution, Macrodex with glucose solution, Rheomacrodex, sodium bicarbonate 1.4%, laevulose 5% and 10%, Ringer lactate, Ringer acetate, dextrose 5% and 10%, saline solution.

Incompatibility: Rimactane Infusion is incompatible with

the following: Perfudex, sodium bicarbonate 5%, sodium lactate 0.167M, Ringer acetate with dextrose.

Rimactane Infusion should not be mixed with other drugs as precipitation may occur; concurrent intravenous therapy should be administered via a different site of injection.

Legal category POM.

Package quantities

Rimactane Infusion 300 mg: Combined pack of 1 vial + 1 × 5 ml solvent ampoule.

Rimactane Infusion 600 mg: Combined pack of 1 vial + 1 × 10 ml solvent ampoule.

Rimactane Infusion 300 mg 0008/0151

Rimactane Infusion 600 mg 0008/0152

RIMACTAZID* COMBINED TABLETS

Presentation Rimactazid 150 Tablets each containing 150 mg rifampicin (Rimactane*) and 100 mg isoniazid, pink, round, bi-convex, sugar-coated tablets, marked with the monogram CIBA on one side and the letters EI on the other.

Rimactazid 300 Tablets each containing 300 mg rifampicin (Rimactane*) and 150 mg isoniazid; brownish orange, capsule-shaped, bi-convex, sugar-coated tablets, marked with the monogram CIBA on one side and the letters DH on the other.

Uses *Mode of action:* Rimactazid contains the semi-synthetic antibiotic Rimactane, which has bactericidal activity against most groups of Mycobacteria, and isoniazid, which is an effective anti-bacterial agent against Mycobacterium tuberculosis.

Indications: Rimactane and isoniazid are both major drugs in the management of tuberculosis and in certain opportunist mycobacterial infections. This combination has been shown to eradicate tuberculosis infection faster and more effectively than any previous regimen. Extensive UK experience has led to the routine use of Rimactane and isoniazid as basic therapy supported in the first six to eight weeks, or until cultures are negative, by a third drug, e.g. streptomycin, pyrazinamide, ethambutol and the majority of second-line drugs. Whilst it is not generally recommended that rifampicin be used in combination with PAS, if for any reason this regimen is used, the drugs should be given not less than eight hours apart to ensure satisfactory blood levels. Rifampicin is effective in cases resistant to other anti-tuberculous agents and shows no cross-resistance outside the rifamycin group of drugs.

Dosage and administration Rimactazid should be given as a single dose, preferably on an empty stomach, if possible 30 minutes before breakfast to ensure a high peak serum concentration. Dosage should be adjusted according to body weight of patients.

Adults: Oral: The combined tablets of Rimactazid provide Rimactane and isoniazid in the accepted ratios to provide the currently recommended adult dose of these two drugs. Thus, 2 tablets daily of Rimactazid 300 are recommended for patients of 50 kg (8 stone) and over and 3 tablets daily of Rimactazid 150 for patients under 50 kg (i.e. the usual daily dosage of 600 mg or 450 mg Rimactane, each with 300 mg isoniazid).

Use in pregnancy and lactation: Rifampicin has been shown to have teratogenic effects in animals on very high doses, therefore during pregnancy the use of Rimactazid should, if possible, be avoided. Particularly during the first 3 months of pregnancy the drug's possible risks to the foetus must be carefully weighed against its therapeutic benefits for the mother.

When administered during the last few weeks of pregnancy, Rimactane can cause post-natal haemorrhages in mother and infant, for which treatment with vitamin K may be indicated.

Rifampicin is excreted in breast milk. Mothers in whom its use proves unavoidable should refrain from breast-feeding their infants.

Contra-indications, warnings, etc *Contra-indications:* Rimactazid is contra-indicated in patients with jaundice or where there is known hypersensitivity to rifamycins and/or isoniazid. The causative agent should be replaced by another antituberculous drug in combination therapy.

Psychotic states characterised by mania and hypomania are contra-indications for isoniazid.

Precautions: As Rimactane and isoniazid are metabolised in the liver, patients with impaired liver function should be treated with caution. Such patients should have liver function monitored during treatment. Any deterioration in liver function in these patients is an indication for stopping treatment.

The occurrence of liver function abnormalities is more common when rifampicin and isoniazid are used in combination and special care is therefore required in patients with pre-existing liver impairment or in the elderly, malnourished or very young patients.

In the presence of complete renal failure rifampicin is excreted entirely in the bile, provided hepatic function is not impaired the dosage of rifampicin need not be adjusted.

When resuming treatment with rifampicin after a temporary interruption or a prolonged interval, the drug should be given in small gradually increasing doses. For this purpose, rifampicin and isoniazid should temporarily be administered in free combination. In adults an initial dose of rifampicin 75 mg daily should be administered, raised subsequently by 75 mg per day until the desired dosage level is attained. During this period, renal function should be closely monitored. If as may happen in exceptional cases the patient develops renal failure, thrombocytopenia, purpura or haemolytic anaemia, treatment with rifampicin should be stopped at once and not re-instituted at a later date. Normal dosage of isoniazid should be continued over this period.

Microbiological techniques for assaying the serum concentrations of folic acid and Vitamin B₁₂ are not suitable for use during treatment with rifampicin.

Care should be taken in giving isoniazid to patients suffering from convulsive disorders, chronic alcoholism or impaired liver or kidney function. Pyridoxine may be useful in preventing the occurrence of peripheral neuritis.

Drug Interactions: Rifampicin is a potent inducer of liver enzymes which may increase the metabolism of concomitantly administered drugs such as corticosteroids, oral contraceptives, oral anti-coagulants, oral anti-diabetic agents, dapsone, some digitalis preparations, quinidine and methadone. The dosage of these drugs may need considerable review when Rimactazid or Rimactane is being prescribed, larger doses being needed when

Rimactazid or Rimactane is introduced and a reduction when either is withdrawn.

In women receiving treatment with rifampicin it has been found that the contraceptive activity of oral contraceptives may be impaired. In such cases, additional non-hormonal methods should be employed.

In patients under treatment with phenytoin, the dosage of this drug should be individually readjusted, because isoniazid raises, and rifampicin lowers its plasma concentration.

It is not advisable to administer isoniazid concomitantly with disulphiram, although the mechanism of this interaction is unclear.

Side effects: *Associated with Rimactane.* Occasionally gastrointestinal disturbance and drug rashes have been reported after treatment with Rimactane.

There may be an elevation of serum bilirubin levels, SGOT and SGPT levels and more rarely alkaline phosphatase during the early stages of treatment.

In patients with previously normal liver function these changes are transient and usually revert towards normal pre-treatment levels in about two weeks even when Rimactane is continued. Routine liver function tests during treatment are unnecessary unless the patient becomes unwell or exhibits frank jaundice. The occurrence of jaundice may call for temporary cessation of treatment however in most patients it is possible to resume therapy. (See Precautions).

In common with other antibiotics, mild leucopenia and eosinophilia have been reported in a few patients, but appear to be of no particular clinical significance and no causal relationship has been established.

Associated with isoniazid: Side-effects with isoniazid are not common, but hypersensitivity reactions characterised by fever, rash and lymphadenopathy do occur. Isoniazid can cause a mood elevating effect in high dosage which can result in more severe manic disturbances. Occasionally peripheral neuritis has been described, also liver function disturbances, blood dyscrasias, rheumatic syndrome and lupus erythematosus – like signs and symptoms. Hyperglycaemia and gynecomastia have also been associated with isoniazid treatment.

Treatment of overdose: There is no specific antidote to Rimactane. In cases of severe overdose gastric lavage may be undertaken and general supportive treatment administered.

Severe overdose of isoniazid has been treated with phenobarbitone given intravenously, pyridoxine and oxygen. Peritoneal dialysis has also been used.

Pharmaceutical precautions Rimactazid Tablets should be protected from heat and moisture. The combined tablets have a shelf-life of four years.

Legal category POM.

Package quantities Rimactazid 150 Tablets (pink) and Rimactazid 300 Tablets (brownish orange) in securitainers of 100.

Further information Rimactane is orally active, very well tolerated and its activity is comparable with that of isoniazid. In combination, these two agents are commonly used as first-line therapy and offer the greatest chance of rapid eradication of the infection. It is usual, however, to employ a third drug during the first two months of treatment or at least until the results of sensitivity tests are known. Continuation therapy with rifampicin and isoniazid has been shown to eradicate the infection in almost all patients faster and with a lower

relapse rate than any alternative regime. The combined tablets of Rimactazid thus make the most effective combination simpler to take. The orange-red colour imparted to the urine, sputum and tears by rifampicin is a valuable guide to drug adherence; rifampicin may also permanently discolour soft contact lenses.

Rimactazid 300 mg 0008/0120

RITALIN*

Presentation Ritalin Tablets each containing 10 mg of methylphenidate hydrochloride, as a circular, flat, white tablet with bevelled edges. The monogram CIBA is impressed on one face and the other is marked with the letters AB and a break line.

Ritalin Ampoules each containing 20 mg methylphenidate hydrochloride as a white lyophilised mass in a clear glass 2 ml ampoule.

Uses Mode of Action: Ritalin has a stimulant effect on the central nervous system.

Indications: Functional behavioural problems in children (Minimal brain dysfunction, hyperkinesia). Narcolepsy.

In anaesthesia for the management of post anaesthetic tremors, including those induced by halothane.

Dosage and administration Adults: Orally the average dose is 20–30 mg daily in 2 doses, 1 before breakfast and 1 before lunch. Parenterally Ritalin may be given subcutaneously, intramuscularly or intravenously, the dose being 10–20 mg to be repeated as required by the clinical response.

For parenteral use the contents of the ampoule should be dissolved in 1 ml of Water for Injection BP. The resulting solution is isotonic.

Note: The parenteral solution should not be injected through tubing or a syringe which contains a barbiturate or a strongly alkaline solution, as a heavy precipitate will be formed.

Children: (over 6 years) Orally 5–10 mg three times daily, increasing if necessary by weekly increments of 5–10 mg in the daily dosage. Doses above 60 mg daily are not recommended. To obviate the risk of insomnia, the last dose should be taken not later than 4 p.m. Ritalin is not indicated in children less than 6 years. Ampoules not recommended for paediatric use.

Contra-indications, warnings, etc Side-effects: Nervousness, insomnia and anorexia are the most common adverse reactions of Ritalin. On rare occasions hypersensitivity reactions, nausea, dizziness, palpitations, headache, dyskinesia, drowsiness and skin rash have been reported. Blood pressure and pulse changes, both raising and lowering, may occur.

Contra-indications: The presence of marked anxiety or tension is a contra-indication to the use of Ritalin, as it may aggravate these symptoms. Ritalin is also contra-indicated in patients with severe angina pectoris, glaucoma, tachyarrhythmias and thyrotoxicosis.

Ritalin should not be used for severe depression of either exogenous or endogenous origin. Ritalin should not be used in patients suffering from epilepsy, or in those with a propensity for dependence on drugs including alcohol. Ritalin should not be given together with pressor agents, MAO inhibitors or tricyclic antidepressants.

Precautions: Ritalin should only be used with extreme caution in patients receiving antihypertensive agents of the adrenergic neurone blocking type, e.g. debrisoquine, guanethidine. High dosage may induce cardiac arrhythmias. Ritalin has also been reported as inhibiting the metabolism of coumarin, anticonvulsants such as phenobarbitone, phenylhydantoin, primidone and also phenylbutazone.

Ritalin may cause dependence so it should be given cautiously to emotionally unstable patients. Chronic abuse can lead to marked tolerance and psychic dependence with varying degrees of abnormal behaviour. Frank psychotic episodes can occur, especially with parenteral abuse.

Overdosage: There is no specific antidote to Ritalin overdosage. Management consists of appropriate supportive measures. Gastric contents may be evacuated by induction of emesis or gastric lavage. Signs and symptoms may include respiratory depression, hypotension and shock, cardiac arrhythmias, hypertension, convulsions or excitation states, hyperthermia. In the treatment of hypotension sympathomimetic agents should not be used. Hypertension may be treated with an alpha-blocker such as Rogitine or a vasodilator such as Apresoline. Convulsions and excitation states may be controlled by the cautious use of diazepam, however this may aggravate respiratory depression. Cardiovascular function, respiration and body temperature should be monitored for several days following the onset of improvement.

Pharmaceutical precautions Protect from light.

Legal category POM: MDA.

Package quantities 10 mg tablets of Ritalin in Securitainers of 100.

20 mg dry ampoules of methylphenidate hydrochloride in boxes of 6 for hospital use only.

Further information Nil.

ROGITINE*

Presentation Clear glass ampoules each containing 50 mg phentolamine mesylate presented as a colourless to pale yellow solution in 5 ml water for injection. Each box contains 5 × 5 ml ampoules. Also available as ampoules containing 10 mg phentolamine mesylate in 1 ml water for injection. Each box contains 6 × 1 ml ampoules.

Uses Mode of Action: Acute, severe cardiac insufficiency is often characterised by a high degree of sympathico-adrenergic stimulation which leads to a pronounced increase in the myocardial oxygen requirement. Marked peripheral vasoconstriction and a rise in left-ventricular filling pressure, accompanied by pulmonary congestion or pulmonary oedema, are usually also present.

In patients with acute, severe cardiac insufficiency, particularly when due to recent myocardial infarction, parenteral administration of Rogitine elicits a prompt improvement in the clinical picture. By acting directly on vascular smooth muscle, by blocking the alpha-receptors, and by indirectly stimulating the beta-receptors,

Rogitine exerts a rapid and potent vasodilator effect which also extends to the venous system. Systemic and pulmonary vascular resistance, as well as left-ventricular filling pressure, are reduced. The work load on the heart is thus diminished – alternatively the level of cardiac performance attained at a given work load is improved. Stroke volume and cardiac output are increased, which has the effect of limiting the fall in blood pressure.

Moreover, the positive inotropic activity of Rogitine also helps to enhance cardiac performance. Rogitine, however, does not unduly accelerate the heart rate; on the contrary, the net result of its various effects is a marked easing of the strain on the heart. Besides its direct haemodynamic effect, the drug also stimulates secretion of insulin, which is reduced in the presence of severe cardiac insufficiency; this stimulant action tends to have a favourable influence on myocardial metabolism. The anti-arrhythmic properties possessed by Rogitine may diminish the occurrence of ventricular or supra-ventricular extra systoles.

Indications: Acute left ventricular failure (cardiogenic shock) particularly following myocardial infarction.

Paroxysmal hypertension associated with phaeochromocytoma or interaction of foodstuffs with MAOI's; and as prophylactic treatment (in combination with a beta-blocker) before and during surgical removal of phaeochromocytoma.

As a diagnostic agent in cases of suspected phaeochromocytoma.

Dosage and administration *Cardiogenic Shock:* The dosage should be individually adapted to the patient's requirements and will depend on the severity of the cardiac insufficiency and on the blood pressure.

Rogitine should be administered in the form of an intravenous infusion in 5% sterile glucose, saline or dextrose saline solution. A dose of 5–60 mg Rogitine should be given over a period of 10–30 minutes at an infusion rate of 0.1–2 mg per minute. If necessary, especially in cases where the systemic arterial blood pressure is elevated, the infusion rate during the first minute can be raised up to 5 mg per minute.

Systolic blood pressure should be carefully monitored during the infusion and a fall below 100 mm Hg is an indication for reducing the infusion rate (see Precautions).

Depending on the patient's response, the treatment can either be continued for several hours or repeated at intervals.

Paroxysmal hypertension: 5–10 mg intramuscularly or intravenously to be repeated if necessary. When used prior to surgical removal of phaeochromocytoma, administer the injection 2 hours before surgery and repeat if necessary during the operation. In children during surgery for the removal of phaeochromocytoma, the dosage is 1 to 5 mg given intravenously according to age.

As a diagnostic test for phaeochromocytoma: This test is based upon the fact that Rogitine produces a fall in blood pressure when it is caused by excess circulating adrenaline and/or noradrenaline, so it is of value only in the hypertensive phase of the paroxysmal type of case. False positives may result from patients suffering from uraemia, or who have received sedatives or narcotics during the twenty-four hours prior to the test.

The initial step in the test is to determine the basal blood pressure of the patient – this is essential for the

correct interpretation of the test. An intravenous injection of 5 mg of Rogitine (1 mg in children) is then administered. As the insertion of the needle may involve a pressor response the blood pressure should be allowed to drop back to within 3 to 4 mm of the basal level before injecting Rogitine.

In the event of a positive response the blood pressure will fall rapidly, and quickly return to basal levels. The blood pressure must be measured at 30 second intervals for 3 minutes after injections, and then every 60 seconds for 7 more minutes.

An immediate marked drop in both systolic and diastolic blood pressure is the typical positive response in patients having a phaeochromocytoma which is discharging adrenaline or noradrenaline at the time of the test. The maximum depressor effect usually occurs within two minutes and usually involves a fall in systolic pressure of about 60 mm and the diastolic fall usually exceeds 25 mm. The blood pressure remains low for only a relatively short time and may return to pre-injection levels within 10–15 minutes. Positive results should be confirmed by either estimation of catecholamines in the urine or by another diagnostic procedure.

False positive results may be seen in patients with uraemia and those having taken sedatives prior to the test.

Whilst false negative results may be seen:

- if at the time of injection the tumour is not discharging sufficient adrenaline or noradrenaline to elevate the blood pressure significantly;
- when a phaeochromocytoma is present in a patient also having essential hypertension, the test may not cause such a marked fall in blood pressure.

The other clinical findings and tests would usually assist in interpreting such results.

The intravenous administration of Rogitine may cause tachycardia in rare instances, weakness, dizziness or flushing, but are not considered serious in relation to the test.

Further details available on request from CIBA Laboratories, Horsham, West Sussex.

Contra-indications, warnings, etc *Contra-indication:* Severe hypotension.

Precautions: Monitoring of the patient's blood pressure, heart rate, and clinical condition is necessary not only to ensure correct selection of cases suitable for treatment with Rogitine but also to decide upon the appropriate dosage and duration of parenteral therapy. As a general rule, a systolic pressure of 80 mmHg should be regarded as the lowest limit at which the drug can still be employed.

Side-effects: When administered in the recommended dosages, Rogitine is generally well tolerated. Hypotension, tachycardia and dizziness may occur, particularly if the drug is given parenterally. Nausea, diarrhoea, and nasal congestion have been reported in response to fairly high doses, but they subside again following discontinuation of the infusion.

Treatment of Overdosage: In the event of overdosage (as evidenced by an excessive fall in blood pressure, or by tachycardia) it is usually sufficient simply to discontinue the infusion; if necessary, the effect of Rogitine can be attenuated by giving noradrenaline.

Pharmaceutical precautions Protect from heat and light.

Legal category POM.

Package quantities

- (a) Ampoules each containing 50 mg Rogitine in 5 ml Water for Injection. Boxes of 5.
- (b) Ampoules each containing 10 mg Rogitine in 1 ml Water for Injection. Boxes of 6.

Rogitine Ampoules 10 mg/1 ml 0008/5070.

SLOW-K®

Presentation Pale orange, polished, sugar-coated tablets about 12 mm in diameter, printed with the name Slow-K, containing 600 mg (8.06 mEq) of Potassium Chloride BP.

Uses Mode of Action: The potassium chloride in Slow-K is finely distributed in a neutral wax base, from which it is gradually released over a period of 3–6 hours during its passage through the digestive tract. This special form of potassium substitution therapy is designed to avoid high localised concentrations of potassium chloride which might irritate or damage the mucosa. The potassium chloride present in Slow-K is completely absorbed in the intestinal tract.

Indications: For the treatment and specific prevention of hypokalaemia especially in cases of the following kinds.

Where protracted or intensive diuretic medication is being given as treatment for hypertension or cardiac failure, and where diuretics have been prescribed to resolve massive oedema. Potassium substitution is of particular importance in patients undergoing concomitant digitalisation because hypokalaemia may cause hypersensitivity to digitalis.

Renal disease associated with increased potassium excretion e.g. nephrotic syndrome.

Liver cirrhosis, especially during diuretic therapy.

Gastro-intestinal disorders accompanied by potassium depletion e.g. chronic diarrhoea, repeated vomiting, ulcerative colitis, status post ileostomy.

Hypochlorhaemic alkalosis, cases in which a low salt diet or prolonged fasting have been imposed and patients receiving an unbalanced diet deficient in potassium.

Protracted or intensive treatment with corticosteroids, ACTH or carbenoxolone, Cushing's syndrome.

Initial treatment for megaloblastic anaemia.

Diabetic ketosis.

In these conditions Slow-K is particularly indicated if a diet rich in potassium cannot be guaranteed.

Dosage and administration Adults: The dosage of Slow-K should be adapted to the cause, degree and duration of potassium depletion. 2–6 tablets are usually an adequate supplement. It is important that the tablets should be swallowed whole, and to ensure the tablets enter the stomach, taken with meals or with a tumbler of water.

In states of severe potassium deficiency, a higher dose of 9–12 tablets daily may be needed. According to the dosage of diuretic used and the needs of the individual patient, a dose ratio of one Slow-K tablet with each tablet of thiazide diuretic will usually suffice when administered as a potassium supplement. However, when the more potent diuretics such as frusemide are used, larger doses of Slow-K may be required. Where

intermittent diuretic therapy is being used it is probably best to continue the Slow-K on the days between the diuretic administration.

Children: At the discretion of the physician.

Contra-indications, warnings, etc Side-effects: Side-effects are rare with Slow-K, as any excess potassium is rapidly excreted in the urine.

In rare cases, oral potassium preparations may provoke gastro-intestinal disturbances (nausea, vomiting, abdominal pains, diarrhoea) necessitating either a reduction in dosage or withdrawal of medication (see Precautions).

Contra-indications: Advanced renal failure, untreated Addison's disease, acute dehydration, hyperkalaemia. All solid forms of potassium medication are contra-indicated in the presence of obstructions in the digestive tract (e.g. resulting from compression of the oesophagus due to dilation of the left atrium or from stenosis of the gut).

Precautions: If a patient under treatment with Slow-K develops severe vomiting, severe abdominal pains or flatulence, or gastro-intestinal haemorrhage, the preparation should be withdrawn at once, because in the presence of an obstruction it could conceivably give rise to ulceration or perforation.

In patients suffering from impaired renal function, special care should be exercised when prescribing potassium salts owing to the risk of their producing hyperkalaemia. Monitoring of the serum electrolytes is particularly necessary in patients with diseases of the heart or kidneys.

To guard against the risk of hyperkalaemia, one should also refrain from administering potassium salts together with potassium-sparing diuretics such as aldosterone antagonists or triamterene.

In cases of metabolic acidosis, the hypokalaemia should be treated not with potassium chloride but with an alkaline potassium salt (e.g. potassium bicarbonate).

Pharmaceutical precautions Slow-K Tablets should be protected from heat, light and moisture. The tablets should be dispensed in moisture-proof containers.

Legal category GSL.

Package quantities Slow-K Tablets (600 mg Potassium Chloride BP in a special slow-release core, equivalent to 8.06 mEq K⁺) Securitainers of 500.

Further information The potassium chloride in Slow-K has been shown to be completely absorbed, but occasionally patients may notice 'ghost' tablet cores in the faeces, these have been shown not to contain any potassium. The administration of Slow-K does not obviate the need to encourage the patient to take an adequate potassium-containing diet.

Product licence number 0008/5039.

SLOW-TRASICOR®

Presentation Slow-Trasicor Tablets each containing 160 mg oxprenolol hydrochloride in a special sustained-release formulation. Circular, slightly bi-convex, white film-coated tablets, having the monogram CIBA impressed on one side and Slow-Trasicor on the other.

Uses Mode of action: Slow-Trasicor Tablets release oxprenolol hydrochloride (a non-selective beta-adren-

ergic receptor blocking drug) gradually from a special sustained release formulation, thus prolonging the pharmacological action.

Slow-Trasicor protects the heart and cardiovascular system against excessive adrenergic stimulation caused by either physical or emotional activity. Accordingly, under conditions of sympathetic drive, heart rate, force of contraction and output are reduced, leading to a fall of myocardial work and oxygen consumption. The extra-cardiac effect of Slow-Trasicor include attenuation of both renin and free fatty acid release.

Slow-Trasicor has partial agonist activity (PAA) also known as intrinsic sympathomimetic activity (ISA). This property means that some degree of stimulation of the beta receptors is maintained. Under conditions of rest, this tends to counterbalance the reduction in heart rate and force of contraction.

Indications: *Hypertension:* All grades of hypertension in once-daily dosage. The concomitant use of a thiazide diuretic will enhance the antihypertensive effect of Slow-Trasicor, resulting in better control from reduced dosage.

Angina pectoris: For continuous prophylaxis in once-daily dosage to improve exercise tolerance and reduce the frequency and severity of anginal attacks. Beta-blocking agents have been shown to improve the medium-term prognosis, by reducing the rate of recurrent complications and death in patients after myocardial infarction.

Anxiety: For the control of anxiety and anxiety tachycardia.

Dosage and administration Slow-Trasicor Tablets release oxprenolol gradually from a special sustained-release formulation. This provides a considerably longer pharmacological action from a given dose, thus allowing once-daily dosage.

Adults: *Hypertension:* Initially one tablet daily, given in the morning. If necessary, this dose can be raised to two or more tablets, usually given once daily until satisfactory blood pressure control is achieved. However, when used as monotherapy, dosage should not exceed 3 tablets daily, i.e. 480 mg Slow-Trasicor, since experience has shown that hardly any increase in the response can be achieved by this means. The addition of a diuretic will often give a quicker and more satisfactory response. Usually, patients respond to a dose of one or two tablets of Slow-Trasicor in combination with a diuretic and most of the antihypertensive effect is achieved within 2-3 days. The addition of a vasodilator will often enable control to be achieved in the minority of patients who might otherwise fail to respond.

Angina pectoris: Initially one tablet daily, given in the morning. This can be increased to two or three tablets, usually given once daily depending on patient response. An evening dose may be beneficial in nocturnal angina. Increased dosage is related to increased exercise tolerance, but doses higher than three tablets should not normally be required. Slow-Trasicor is compatible with glyceryl trinitrate and the two drugs are complementary since they reduce heart work by different mechanisms. It may be possible, however, to reduce the use of glyceryl trinitrate when the patient has become established on Slow-Trasicor.

As with other beta-blocking drugs, sudden withdrawal of treatment may induce severe and continuous angina. Patients should, therefore, be advised to avoid interrup-

tion of established therapy and if withdrawal becomes necessary it should be done gradually.

Anxiety states: One tablet daily. Although no evidence of habituation or tolerance has been observed with Trasicor its effectiveness in the long term treatment of anxiety has not been established. In the treatment of transient situational anxiety it may be appropriate to prescribe a single dose of 40-80 mg conventional Trasicor. Trasicor can be administered concurrently with benzodiazepines. When withdrawal of pre-existing anxiolytic therapy is indicated this should take place gradually.

Contra-indications, warnings, etc *Side-effects:* Slow-Trasicor is well tolerated. However, dizziness, drowsiness, headache, insomnia, excitement and gastrointestinal disturbance may occur particularly at the start of treatment. Like other beta-blockers, isolated cases of excessive bradycardia and thrombocytopenia have been reported. As with other beta-blockers, bronchospasm and heart failure may occasionally be precipitated in susceptible patients (see Precautions) and exertional tiredness and feelings of coldness in the extremities have been reported on rare occasions. However, the incidence of these side-effects is low, possibly due to the partial protection afforded by the sympathomimetic effect of Slow-Trasicor.

Slow-Trasicor possess antihypertensive effects but these are unlikely to be noted in normotensive subjects.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small, and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual.

Contra-indications: Slow-Trasicor is contra-indicated in patients with atrio-ventricular block, marked bradycardia, uncontrolled heart failure and cardiogenic shock.

Precautions: If there is evidence of cardiac failure this must be controlled by digitalis and/or diuretics before and during Slow-Trasicor therapy. Should the pulse rate fall below 50 per minute, then treatment should be restarted at a lower dose. Caution should be observed when treating asthmatics, chronic bronchitis or other individuals where bronchospasm may be provoked. Slow-Trasicor should be given cautiously to patients with metabolic acidosis, or anaesthesia with ether or chloroform. For anaesthesia the agent selected should be one exhibiting as little negative inotropic activity as possible e.g. halothane, nitrous oxide. Treatment with a beta-blocker is liable to mask symptoms of hypoglycaemia and also to affect carbohydrate metabolism. In patients with labile or insulin dependent diabetes in particular, it may therefore be necessary to readjust the dosage of anti-diabetic medication.

Beta-blockers may cause bradycardia in the fetus which can also persist after birth. During pregnancy, in the course of labour and during lactation beta-blockers should only be employed after the needs of the mother have been weighed against the possible risks to the fetus.

Treatment of overdosage: Overdosage with Slow-Trasicor may lead to excessive bradycardia, hypotension, coma and convulsions. It should also be noted that severe toxicity may develop rapidly and that there may be severe hypotension and bradycardia despite a normal

ECG. For sinus bradycardia and hypotension 0.5–2.0 mg of atropine should be slowly administered by intravenous infusion. If this does not raise the heart rate sufficiently isoprenaline may be necessary. The dose of isoprenaline needs to be sufficient to reverse the blockade and should be assessed by the clinical response. A reasonable starting dose would be 25 mcg of isoprenaline hydrochloride.

In severe cardiogenic shock the treatment of choice appears to be glucagon. The initial dose should be 5–10 mg intravenously, further boluses or an infusion can be used according to the patient's condition. Transvenous pacing has been used, sometimes with success. If bronchospasm develops bronchodilators should be used. Patients should be monitored for several days as the beta-blocking effects of Slow-Trasicor exceed its plasma half-life.

Pharmaceutical precautions The tablets have no special storage requirements.

Legal category POM.

Package quantities Cartons of 28 Slow-Trasicor Tablets consisting of two reminder calendar foils of 14. (Each carton of 28 represents 2–4 weeks' treatment, depending on whether storage is one or two tablets daily).

Further information Slow-Trasicor is a sustained release preparation of Trasicor* (oxprenolol hydrochloride) designed to release oxprenolol so that maximal response is obtained within 1–2 hours (as with plain Trasicor tablets), whilst the pharmacological action is sustained for 24 hours. Thus Slow-Trasicor produces a smoother absorption of Trasicor and by levelling out peak serum concentrations, avoids 'wastage' and minimises unwanted effects of beta-blockade. Accordingly, there is greater utilisation of Trasicor (oxprenolol) mg for mg (i.e. greater distance walked by an anginal patient before the onset of pain) with Slow-Trasicor.

Trasicor protects the cardiovascular system from excess adrenergic discharge and the resulting elevation of catecholamine levels which are a known risk factor in coronary heart disease and which in the long term, may contribute to the secondary effects of hypertension.

Trasicor prevents emotional tachycardia during environmental stress. In anxiety, Trasicor does not produce sedation or cause dependence. The best response is seen in patients who have not previously received benzodiazepines.

Slow-Trasicor is presented in day-of-the-week calendar packs to improve patient compliance.

Product licence number 0008/0130.

SYNACTHEN*

Presentation A clear, colourless, sterile solution containing 0.25 mg tetracosactrin per ml. This preparation is available in 1 ml ampoules.

Uses *Mode of action:* Synacthen is a synthetic polypeptide with corticotrophic activity and a short duration of action. Synacthen consists of the first 24 amino acids occurring in natural adrenocorticotrophin.

Indications: Since Synacthen has all the properties of natural ACTH it can be used in all situations where a short acting ACTH preparation is indicated, e.g. bronchial asthma, but only if other therapeutic measures have failed and under strict medical supervision. Also as a

diagnostic test for the investigation of adrenocortical insufficiency.

Dosage and administration Synacthen may be given by intravenous or intramuscular or subcutaneous injection.

Adult dosage for therapeutic use: Intravenously 0.25 mg of Synacthen in 500 ml of infusion fluid (isotonic dextrose or other electrolyte solution) over a six-hour period. By intramuscular injection 0.25 mg every three to four hours.

As a diagnostic aid: Withdraw 5–8 ml of venous blood into a heparinised tube, then inject intramuscularly 0.25 mg of Synacthen. After 30 minutes withdraw a further 5–8 ml into a heparinised tube, centrifuge the blood specimen, measure plasma hydroxycorticoids and interpret the results. (The Mattingly method is suitable.)

For a normal test the initial level of plasma cortisol should be greater than 5 mcg/100 ml (138 nmol/l), provided that the patient has not received a glucocorticoid within the previous 12 hours. The plasma cortisol level 30 minutes after the injection of Synacthen should be greater than 18 mcg/100 ml (500 nmol/l) irrespective of the initial level, and should have risen by at least 7 mcg/100 ml (200 nmol/l).

Synacthen should not be added to blood or plasma transfusions as it is liable to be inactivated by the enzymes.

When administering Synacthen for a therapeutic effect the route of choice is by intravenous infusion in isotonic dextrose or electrolyte solution. The route of infusion is important. It is suggested that 500 ml containing 0.25 mg of Synacthen should be given over six hours at the rate of approximately 24 drops per minute. When given intravenously 1 mg of Synacthen is equivalent in activity to approximately 100 units of corticotrophin.

Contra-indications, warnings, etc *Contra-indications:* Hypersensitivity reactions may occur in response to Synacthen particularly in patients with allergic disorders or with an allergic diathesis. In rare cases these may be of a serious nature and take the form of anaphylactic reactions, which normally occur within 30 minutes. Such reactions should be considered an absolute contra-indication to further treatment with this polypeptide.

Milder reactions of an allergic or hypersensitive nature should also be considered as an indication that the course of treatment should be stopped and not restarted, since a trivial reaction may be followed by a more serious event if further injections are given. These milder reactions include urticaria, pruritis, flushing and faintness and dyspnoea. Since some reactions have occurred without warning wherever possible patients should remain at the hospital or doctor's surgery for a recovery period following an injection.

As with any treatment that may carry an allergic risk injections of Synacthen should be administered under medical supervision and in the event of a severe anaphylactic reaction occurring despite these precautions, the following measures are recommended: administer 0.5 mg adrenaline s.c. or i.m. as well as a large i.v. dose of corticosteroid for example 50–100 mg prednisolone as prednisolone sodium phosphate BP, repeating the dose if necessary.

The doctor should routinely enquire about possible previous reactions to Synacthen or drugs in general and about a past history of allergic disorders.

Synacthen is contra-indicated in patients allergic or sensitive to Synacthen Depot; in acute psychoses, in the

presence of systemic infections without specific anti-infective therapy, in Cushing's syndrome and in patients with peptic ulcer and heart failure. Synacthen is also contra-indicated during pregnancy.

Precautions: Synacthen should be used cautiously in patients hypersensitive to ACTH of animal origin; and in patients suffering from diabetes mellitus or hypertension, where the dosage of concomitant medication may need adjustment.

Side-effects: When employed as a therapeutic agent, Synacthen is liable to give rise to side-effects which are due to the drugs hormonal activity e.g. sodium and water retention, raised blood pressure, hypokalaemia, hyperglycaemia, increased susceptibility to infection, Cushing's syndrome, hyperpigmentation and psychological disturbances. The more serious side-effects usually associated with steroids, peptic ulcer, osteoporosis, retarded wound healing and myopathy are less frequent. Troublesome side-effects are often an indication of overdosage.

Pharmaceutical precautions Synacthen should be protected from heat and light.

Legal category POM.

Package quantities Synacthen Ampoules 0.25 mg per ml in boxes of 6.

Further information Nil.

Product licence number 0008/0034.

SYNACTHEN* DEPOT

Presentation Tetracosactrin Acetate BP with zinc injection. A sterile white suspension, which settles on standing, containing 1 mg of Synacthen per ml. The preparation is intended for intra-muscular injection, and is available in 1 ml ampoules and 2 ml multi-dose vials.

Uses *Mode of action:* Synacthen is a synthetic polypeptide consisting of the first 24 amino acids of the naturally occurring anterior pituitary hormone ACTH. These 24 amino acids are the ones responsible for the corticotropic activity. Those numbering 25 to 39, some of which vary from one species to another, but which do not appear necessary for corticotropic activity, are omitted. Synacthen thus has the same biological action as natural human ACTH. Synacthen is a hexa-acetate. In the depot form it is adsorbed on to a zinc phosphate complex, to prolong its action.

Indications: For the treatment of rheumatoid arthritis and other allied rheumatic conditions, including juvenile rheumatoid diseases and rheumatic fever, acute gout, psoriatic arthropathy, dermatomyositis, asthma but only in exceptional cases (see contra-indications, warnings, etc.), chronic skin disorders such as pemphigus, generalised bullous or exfoliative dermatitis, dermatitis herpetiformis and erythrodermia, nephrotic syndrome, ulcerative colitis, Crohn's Disease, acute neurological conditions such as exacerbations of multiple sclerosis, Guillain-Barré syndrome, Bell's paralysis, optic neuritis, systemic lupus erythematosus, hypsarrhythmia and periorthritis nodosa. To transfer or wean patients from corticosteroid therapy.

Dosage and administration Synacthen Depot should be given intramuscularly, preferably into the buttock.

Adults: Usually 0.5–1 mg twice a week (sometimes less or at longer intervals according to response). For best results the dosage regime should be tailored to individual requirements.

In acute cases, 1 mg i.m. daily for three days. A maintenance regime should be adopted as soon as an adequate response is obtained. The cortisol response is rapid and lasts about 28 hours, the clinical response usually lasts longer.

Infants: Initially 0.25 mg daily by i.m. injection. Maintenance dose 0.25 mg every two to eight days.

Small children: Initially 0.25–0.5 mg daily by i.m. injection. Maintenance dose 0.25–0.5 mg every two to eight days.

Children of school age: Initially 0.25–1 mg daily by i.m. injection. Maintenance dose 0.25–1 mg every two to eight days.

If secondary adrenocortical atrophy has occurred, Synacthen Depot can restore adrenal responsiveness over three or four days. This effect may be utilised in weaning patients from corticosteroid therapy. 1 mg of Synacthen Depot being given daily for three days, the steroid dosage being reduced by a quarter each day. If desired the adrenal responsiveness may be checked, using the 30-minute Synacthen test. A further course of Synacthen Depot may be given if necessary.

Contra-indications, warnings, etc Hypersensitivity reactions may occur in response to Synacthen Depot, particularly in patients with allergic disorders or with an allergic diathesis. In rare cases these may be of a serious nature and take the form of anaphylactic reactions, which normally occur within 30 minutes. Such reactions should be considered an absolute contra-indication to further treatment with this polypeptide. Milder reactions of an allergic or hypersensitive nature should also be considered as an indication that the course of treatment should be stopped and not restarted, since a trivial reaction may be followed by a more serious event if further injections are given. These milder reactions include urticaria, pruritus, flushing and faintness and dyspnoea. Since some reactions have occurred without warning wherever possible patients should remain at the hospital or doctor's surgery for a recovery period following an injection. As with any treatment that may carry an allergic risk, injections of Synacthen Depot should be administered under medical supervision and in the event of a severe anaphylactic reaction occurring despite these precautions, the following measures are recommended: administer 0.5 mg adrenaline s.c. or i.m. as well as a large i.v. dose of corticosteroid for example 50–100 mg prednisolone as Prednisolone Sodium Phosphate BP, repeating the dose if necessary.

The doctor should routinely enquire about possible previous reactions to Synacthen Depot or drugs in general and about a past history of allergic disorders.

Synacthen Depot is also contra-indicated in acute psychoses, in the presence of systemic infections without specific anti-infective therapy, in Cushing's Syndrome, in patients with peptic ulcer, heart failure and during pregnancy. Synacthen Depot is contra-indicated for use by the intravenous route.

Side-effects: Glucocorticoid effects such as 'moon face', raised blood sugar, psychological disturbances and decreased resistance to infection may occur with Synacthen Depot. Mineralocorticoid and androgenic effects such as hypertension, water retention, and weight gain, acne, hirsutism, skin pigmentation and disturbances of

the menstrual cycle can sometimes be troublesome. On the other hand the more serious side-effects usually associated with steroids – such as gastric pain and ulcer formation, skin atrophy, bruising, retarded wound healing, osteoporosis and myopathy – are less frequent. Troublesome side-effects are often an indication of overdosage.

Provided the dosage is carefully individualised, Synacthen Depot is unlikely to inhibit growth in children. Nevertheless in children undergoing long-term treatment, growth should be monitored.

Precautions: Synacthen Depot should be used cautiously in patients hypersensitive to ACTH of animal origin and in patients suffering from diabetes mellitus or hypertension, where the dosage of concomitant treatment may need adjustment.

Overdosage: Overdosage may temporarily lead to fluid retention and signs of excessive adrenocorticotrophic activity (Cushing's Syndrome). In such cases the interval between injections should be extended or dosage reduced as necessary. An oral diuretic may be given, but it is wise to give a potassium supplement, e.g. 'Slow-K'.

Pharmaceutical precautions Synacthen Depot should be stored in a refrigerator (2–6°C) and protected from light. Before administration, it should be well shaken.

Legal category POM.

Package quantities Ampoules of 1 mg in 1 ml packed in boxes of 10.

Multi-dose vials of 2 mg in 2 ml, packed singly.

Further information Synacthen Depot is a free-flowing, fine suspension which can be easily injected using a fine needle.

Since it contains a shorter chain molecule which is not 'foreign' to the human species it may often be well tolerated by patients who are sensitive to animal-extracted ACTH.

The Depot formulation, an inorganic complex, is much longer acting than the gel or CMC forms of ACTH. Thus injections of Synacthen Depot can be more widely spaced. The therapeutic effect far outlasts the cortisol response.

Long-term treatment with Synacthen Depot does not cause adrenal suppression. In fact Synacthen Depot is frequently used to wean patients off steroids. Many cases have been reported where it has eventually been possible to withdraw the Synacthen Depot also, even in patients who initially showed evidence of considerable adrenal atrophy.

TRASICOR®

Presentation Trasicor Tablets each containing 20 mg oxprenolol hydrochloride. Circular, flat, white, film-coated tablets with bevelled edges, having the monogram CIBA impressed on one side and Trasicor 20 on the other.

Trasicor Tablets each containing 40 mg oxprenolol hydrochloride. Circular, flat, white, film-coated tablets with bevelled edges, having the monogram CIBA impressed on one side and Trasicor 40 on the other.

Trasicor Tablets each containing 80 mg oxprenolol

hydrochloride. Circular, pale yellow, slightly bi-convex, film-coated tablets having the monogram CIBA impressed on one side and Trasicor 80 on the other.

Trasicor Tablets each containing 160 mg oxprenolol hydrochloride. Circular, pale orange, slightly bi-convex, film-coated tablets, having the monogram CIBA impressed on one side and Trasicor 160 on the other.

Trasicor Ampoules each containing 2 mg oxprenolol hydrochloride. A white lyophilised mass supplied in a clear glass 2 ml size ampoule.

Uses Mode of action: Trasicor is a beta-adrenergic receptor blocking drug. Its principal effects are seen on the heart where the rate is slowed (negative chronotropic effect) with consequent reduction in heart work and myocardial oxygen consumption.

Trasicor provides effective prophylactic control of angina throughout the day in the majority of patients. The frequency and severity of anginal attacks are reduced, whether precipitated by exercise or emotional stress, and exercise tolerance is improved. ST segment depression seen on exercise is also reduced.

Trasicor has partial agonist activity (PAA) also known as intrinsic sympathomimetic activity (ISA). This property means that some degree of stimulation of beta receptors is maintained. Under conditions of rest this tends to balance the negative chronotropic and negative inotropic effects. Trasicor blocks the effects of excessive catecholamine stimulation resulting from stress.

The mechanism of the antihypertensive effect of Trasicor is not clearly understood. Whilst haemodynamic effects on cardiac output and peripheral resistance appear to be factors, effects on plasma renin and/or the central nervous system may be of significance.

Indications: For the treatment of angina pectoris, all grades of hypertension and sympathetically induced cardiac arrhythmias. For the control of anxiety and anxiety tachycardia. Subsidiary indications include functional heart disorders, hypertrophic obstructive cardiomyopathy, as an adjunct to the treatment of thyrotoxicosis and dysrhythmias associated with anaesthesia.

Dosage and administration Adults: Angina pectoris: Most patients respond to 40–160 mg three times daily. Individual patients may require more, but only rarely are doses above 480 mg daily required.

Trasicor is compatible with glyceryl trinitrate and they are complementary since they reduce heart work by different mechanisms. It is usually possible, however, to reduce or even discontinue the use of glyceryl trinitrate when the patient has become established on Trasicor.

As with other beta-blocking drugs, sudden withdrawal of treatment with Trasicor may induce severe and continuous angina. Patients should, therefore, be advised to avoid interruption of established therapy and if withdrawal becomes necessary it should be done gradually.

Hypertension: Initially 80 mg twice daily. If necessary this daily dose can be increased at convenient intervals (e.g. weekly or fortnightly) until satisfactory blood-pressure control is achieved. When used as monotherapy doses of 480 mg/day should not be exceeded, since experience has shown that hardly any increase in the response can be achieved by this means. The addition of a diuretic will often give a quicker and more satisfactory response. Usually, patients respond to a dose of 80–320 mg Trasicor in combination with a diuretic and most of the antihypertensive effect is achieved within 2–3 days. The addition of a vasodilator will often enable

control to be achieved in the minority of patients who might otherwise fail to respond.

Cardiac arrhythmias: Initial dose 20–40 mg three times daily. This may be increased if necessary to achieve the desired effect.

Trasicor Ampoules 2 mg for parenteral use. Trasicor may be given intramuscularly or intravenously for the emergency treatment of severe cardiac arrhythmias. The recommended starting dose is 2 mg dissolved in 10 ml Water for Injection BP or Injection of Sodium Chloride BP and given slowly, i.e. over 30 seconds, by intravenous injection. If there has been no adequate response within 5 minutes, additional doses of 2 mg, followed by 4 mg, then 8 mg can be given at 5-minute intervals, giving a maximum cumulative dosage of 16 mg in cases of persistent atrial arrhythmias.

N.B. Parenteral administration should be restricted to patients in hospital, preferably under ECG control.

Anxiety states: The majority of patients will respond to a total daily dose of 160 mg. Although no evidence of habituation or tolerance has been observed with Trasicor, its effectiveness in the long term treatment of anxiety has not been established. In the treatment of transient situational anxiety a single dose of 40–80 mg of Trasicor may be prescribed. Trasicor can be administered concurrently with benzodiazepines. When withdrawal of pre-existing anxiolytic therapy is indicated, this should take place gradually.

Hyperthyroidism: 40–120 mg daily in 2 or 3 divided doses.

Pre-operatively: Patients with thyrotoxicosis and phaeochromocytoma may be managed on 60 mg daily in three divided doses. Atropine must always be used pre-operatively.

Anaesthesia: 2 mg ampoules. For the management of prophylaxis of anaesthetic arrhythmias up to 2 mg should be given by slow intravenous injection. Patients should be fully atropinised. Further doses of up to 2 mg at a time may be administered cautiously as required for the management of resistant cases or to maintain the effect.

In patients undergoing elective surgery, it may be considered desirable to employ a beta-blocker as pre-medication, by shielding the heart against the effects of stress, the beta-blocker may serve to guard against excessive sympathetic stimulation, which is liable to provoke such cardiac disturbances as arrhythmia or acute coronary insufficiency. In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible, e.g. halothane, nitrous oxide. If, on the other hand, inhibition of sympathetic tone during the operation is regarded as undesirable, the beta blocker can be withdrawn gradually prior to surgery.

Children: Occasionally Trasicor has been given to children and infants to control arrhythmias. No dosage scheme has been worked out but oral Trasicor has been given empirically on a body-weight basis of approximately 1 mg/kg.

Contra-indications, warnings, etc *Side-effects:* Trasicor is well tolerated. However dizziness, drowsiness, headache, insomnia, excitement and gastro-intestinal disturbance may occur particularly at the start of treatment. Isolated cases of excessive bradycardia and thrombocytopenia have been reported.

As with other beta-blockers, bronchospasm and heart failure may occasionally be precipitated in susceptible

patients (see 'Precautions') and exertional tiredness and feelings of coldness in the extremities have been reported on rare occasions. However, the incidence of these side-effects is low, possibly due to the partial protection afforded by the sympathomimetic effect of Trasicor.

Trasicor possesses antihypertensive effects, but these are unlikely to be noted in normotensive subjects.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small, and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual.

Contra-indications: Trasicor is contra-indicated in patients with atrioventricular block, marked bradycardia, uncontrolled heart failure and cardiogenic shock.

Precautions: If there is evidence of cardiac failure, this must be controlled by digitalis and/or diuretics before and during Trasicor therapy. Should the pulse rate fall much below 50 per minute, then treatment should be withdrawn and re-started at a lower dose. Caution should be observed when treating asthmatics, chronic bronchitis or other individuals where bronchospasm may be provoked. Trasicor should be given cautiously to patients with metabolic acidosis or anaesthesia with ether or chloroform (see Dosage and Administration). Treatment with a beta-blocker is liable to mask symptoms of hypoglycaemia and also to affect carbohydrate metabolism. In patients with labile or insulin dependent diabetes in particular, it may therefore be necessary to readjust the dosage of anti-diabetic medication. Like other beta-blockers, Trasicor should not be given in combination with calcium antagonists of the verapamil type, because their concomitant use may result in bradycardia, hypotension or even cardiac arrest.

Beta-blockers may cause bradycardia in the fetus which can also persist after birth. During pregnancy and in the course of labour and during lactation beta-blockers should only be employed after the needs of the mother have been weighed against the possible risks to the fetus.

Treatment of overdosage: Overdosage with Trasicor may lead to excessive bradycardia, hypotension, coma and convulsions. It should also be noted that severe toxicity may develop rapidly and that there may be severe hypotension and bradycardia despite a normal ECG. For sinus bradycardia and hypotension 0.5–2.0 mg of atropine should be administered slowly by intravenous infusion.

If this does not raise the heart rate sufficiently isoprenaline may be necessary. The dose of isoprenaline needs to be sufficient to reverse the blockade and should be assessed by the clinical response. A reasonable starting dose would be 25 mcg of isoprenaline hydrochloride.

In severe cardiogenic shock the treatment of choice appears to be glucagon. The initial dose should be 5–10 mg intravenously, further boluses or an infusion can be used according to the patient's condition. Transvenous pacing has been used, sometimes with success. If bronchospasm develops bronchodilators should be used. Patients should be monitored for several days as the beta-blocking effects of Trasicor exceed its plasma half-life.

Pharmaceutical precautions The ampoules should

be protected from light; the tablets have no special storage requirements.

Legal category POM.

Package quantities

20 mg Tablets: 100s and 500s.

40 mg Tablets: 100s and 500s.

80 mg Tablets: 100s.

160 mg Tablets: 100s.

All Trascor Tablets packed in Securitainers.

Ampoules 2 mg: Boxes of 5.

Further information In hypertension, Trascor blocks only the beta-receptors and does not share the problems usually associated with other antihypertensive therapy, e.g. postural effects, failure of ejaculation, diarrhoea. Mental and physical lethargy is not a problem with Trascor, many patients reporting an increased sense of well-being.

Trascor protects the cardiovascular system from excess adrenergic discharge and the resulting elevation of catecholamine levels, which are a known risk factor in coronary heart disease and which, in the long term, may contribute to the secondary effects of hypertension.

Trascor prevents emotional tachycardia during environmental stress. In anxiety, Trascor does not produce sedation or cause dependence. The best response is seen in patients who have not previously received benzodiazepines.

TRASIDREX ▼

Presentation Trasidrex tablets each contain 160 mg oxprenolol hydrochloride in a sustained release core and 0.25 mg cyclopenthiiazide in the coat. The tablets are circular, with a red sugar coat, and printed CIBA on one side and TRASIDREX on the other, both words in black.

Uses *Mode of action:* Trascor* (oxprenolol) is a non-selective beta-adrenergic receptor blocking drug with antihypertensive properties. It exerts a competitive and reversible blockade of the beta-adrenergic receptors, thereby protecting the cardiovascular system against excessive adrenergic stimuli, such as those produced by emotional stress and environmental factors. Oxprenolol also has partial agonist activity (PAA) also known as intrinsic sympathomimetic activity (ISA). This property means that some degree of stimulation of the beta receptors is maintained. Under conditions of rest this tends to counter-balance the negative chronotropic and negative inotropic effects of beta-blockade.

The gradual release of oxprenolol from a special sustained release core in Trasidrex prolongs its pharmacological action to 24 hours.

Navidrex* (cyclopenthiiazide) is a thiazide diuretic with sustained antihypertensive activity.

The combination of cyclopenthiiazide and a slow-release formulation of oxprenolol in a single tablet has a number of advantages:

1. Since oxprenolol and cyclopenthiiazide have different modes of antihypertensive activity their therapeutic actions are complementary.

2. Once daily dosage with the combination improves patient compliance.

3. Trascor inhibits the rise in renin caused by diuretics alone. Conversely Navidrex may be expected to improve the response in low renin hypertensives.

4. The addition of Navidrex to Trascor further reduces the minimal risk of cardiac failure.

Indications: In the treatment of mild and moderate hypertension.

Dosage and administration *Adults:* Initially 1 tablet daily, usually given in the morning. Most of the antihypertensive effect of the combination is achieved within two to three days. If necessary, the dose can be increased to 2 or more tablets given once daily, until satisfactory blood pressure control is achieved. Most patients should respond to 1 or 2 tablets.

Trasidrex can be successfully combined with other single antihypertensive drugs having a different pharmacological effect. In particular, a free combination with a vasodilator will often be beneficial.

Contra-indications, warnings, etc *Side-effects:* Trasidrex is well tolerated. However dizziness, drowsiness, headache, insomnia, excitement and gastrointestinal disturbances may occur, particularly at the start of treatment. Like other beta-blockers, there have been isolated reports of bradycardia and thrombocytopenia.

As with other beta-blockers, bronchospasm, and heart failure may occasionally be precipitated in susceptible patients (see precautions) and exertional tiredness and feelings of coldness in the extremities have been reported on rare occasions. However, the incidence of these side-effects is low, possibly due to the partial protection afforded by the sympathomimetic effect of Trascor.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small, and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual.

Like other diuretics with a similar mode of action, cyclopenthiiazide may cause latent gout or latent diabetes mellitus to become manifest. In a few cases, allergic skin reactions, mild anorexia, nausea, constipation and diarrhoea have been reported. In common with other thiazides, there have been isolated reports of thrombocytopenia.

In contrast with other antihypertensive agents, Trasidrex does not cause postural hypotension, sedation or interference with sexual function.

Contra-indications: Trasidrex is contra-indicated in patients with atrio-ventricular block, marked bradycardia, uncontrolled heart failure and cardiogenic shock. Because of the cyclopenthiiazide content, it is contra-indicated in patients with marked renal insufficiency.

An antidiuretic effect has been reported following concomitant treatment with thiazide diuretics and lithium. As with all products which contain thiazide diuretics Trasidrex is contra-indicated during lithium treatment.

Pregnancy: Beta-blockers may cause bradycardia in the fetus, which can also persist after birth. During pregnancy, in the course of labour and during lactation beta-blockers should only be employed after the needs of the mother have been weighed against the possible risks to the fetus.

Precautions: If there is evidence of cardiac failure, this

must be controlled by digitalis before and during trasidrex therapy. Should the pulse rate fall below 50 per minute, treatment should be re-started at a lower dose, if feasible. Particular caution should be observed when treating asthmatics, chronic bronchitics or other individuals where bronchospasm may be provoked.

Trasidrex should be given cautiously to patients with metabolic acidosis or anaesthesia with ether or chloroform. For anaesthesia the agent selected should be one exhibiting as little negative inotropic activity as possible e.g. halothane, nitrous oxide.

Treatment with a beta-blocker is liable to mask the symptoms of hypoglycaemia and also to affect carbohydrate metabolism. In patients with labile or insulin-dependent diabetes in particular, it may therefore be necessary to readjust the dosage of anti-diabetic medication. Navidrex, a thiazide diuretic, may also decrease glucose tolerance.

Like other beta-blockers, Trasidrex should not be given in combination with calcium-antagonists of the verapamil type, because their concomitant use may result in bradycardia, hypotension or even cardiac arrest.

As with other beta-blocking drugs, sudden withdrawal of treatment with Trasidrex may induce severe and continuous angina. Patients should, therefore, be advised to avoid interruption of established therapy and if withdrawal becomes necessary it should be done gradually.

Because of its Navidrex content, Trasidrex should be used with care in patients with some degree of renal impairment, as a rise in blood urea can occur and in extreme cases result in an oliguric crisis.

During long-term treatment with Trasidrex, salt restriction is unnecessary.

The potassium sparing action of Trasacor may obviate the necessity of giving potassium supplements to counter the effects of the thiazide.

Treatment of overdosage: Overdosage with Trasidrex may lead to excessive bradycardia, hypotension, coma and convulsions. It should also be noted that severe toxicity may develop rapidly and that there may be severe hypotension and bradycardia despite a normal C.G. For sinus bradycardia and hypotension 0.5–2.0 mg of atropine should be administered slowly by intravenous fusion. If this does not raise the heart rate sufficiently isoprenaline may be necessary. The dose of isoprenaline needs to be sufficient to reverse the blockade and should be assessed by the clinical response. A reasonable starting dose would be 25 mcg of isoprenaline hydrochloride.

In severe cardiogenic shock the treatment of choice appears to be glucagon. The initial dose should be 5–10 mg intravenously, further boluses or an infusion can be used according to the patient's condition. Transvenous pacing has been used, sometimes with success. If bronchospasm develops bronchodilators should be used. Patients should be monitored for several days as the beta-blocking effects of Trasidrex exceed its plasma half-life. Because Trasidrex is a slow-release formulation, it is likely that the effects of overdosage will be more persistent than following conventional oxprenolol. Further information may be obtained from CIBA Laboratories, Horsham.

Pharmaceutical precautions The tablets should be protected from heat, light and moisture.

Legal category POM.

Package quantities Cartons of 28 tablets consisting of two reminder calendar foils of 14 tablets (each carton of 28 represents two to four weeks' treatment depending on whether dosage is 1 or 2 tablets daily).

Further information By combining a beta-blocker (Trasacor[®]) and a thiazide diuretic (Navidrex[®]) in a single tablet in a calendar pack, the management of hypertension can be greatly simplified for the majority of patients. Compliance will be improved and many of the pharmacological actions of the two components produce beneficial complementary effects.

Product licence number 0008/0138.

VARBIAN ▼

Presentation A clear, colourless solution containing 1 mg/1 ml prenalterol hydrochloride in 5 ml ampoules.

Indications: Varbian is indicated in adult patients who specifically require inotropic stimulation in the following conditions only: management of cardiac failure or hypotension associated with myocardial infarction, in open heart surgery, shock, or in the abolition or reduction of the cardiac effects of beta-adrenoceptor blockade.

Mode of action: Varbian is a β_1 -selective adrenoceptor stimulant. Varbian thus stimulates β_1 -receptors in the heart in doses which have no significant effect on β_2 -receptors in the lungs and blood vessels. Varbian has a more pronounced effect on cardiac contractility than on heart rate. Cardiac output increases mainly as a result of increased stroke volume. An increase of heart rate may be seen. Varbian increases the systolic blood pressure with little or no effect on diastolic pressure. Since Varbian rapidly reverses the haemodynamic effects of β -blockers, the compound may be used to abolish or reduce the cardiac action of β -blockers where this is desirable.

Dosage and administration 1. To abolish or reduce the cardiac effects of β -adrenoceptor blockade, Varbian should be given in doses of 2–5 mg i.v. Varbian should be administered cautiously, generally over a 5-minute period depending on the acuteness of the situation. The optimal effect of each dose is generally achieved within 2–5 minutes, after which further doses may be given to a maximum of 20 mg total. Larger doses of Varbian may be necessary in patients who have taken β -adrenoceptor blocking agents in excess of the recommended dose.

2. For the management of cardiac failure or hypotension associated with myocardial infarction, in open heart surgery, or shock, Varbian should be given by slow intravenous infusion, at a rate of 0.5 mg/minute. However, the rate of administration and duration of therapy should be adjusted according to the patient's response as determined by heart rate, blood pressure and, if possible, cardiac output. The maximum total dose used in clinical trials has been 20 mg.

Contra-indications, warnings, etc *Side effects:* Palpitations and nervousness may occur. Isolated ventricular ectopic beats have been observed. In some patients with a history of angina pectoris Varbian has caused an increase in anginal attacks.

Precautions: Hypovolaemia should be corrected before giving Varbian. Varbian should be used with caution in patients with angina pectoris and recent myocardial infarction (during the first 6 weeks post-infarct). Varbian should be used with caution in patients with hypokalaemia. Patients with uncontrolled or insulin-dependent

diabetes should be kept under careful observation. Varbian should be used with great caution in patients with obstructive subvalvular cardiomyopathy, as inotropic agents may exacerbate the obstruction to flow in these patients.

If an excessive increase in blood pressure or heart rate occurs and it is desired to counteract the effects of Varbian, a β -adrenoceptor blocking agent should be given intravenously.

Pregnancy: Animal toxicity studies at high doses have indicated an increased occurrence of foetal abnormalities of the thoracic cage and cardiovascular system. However, the significance of this in man is uncertain. Nevertheless, benefit-risk should be considered before administering Varbian to pregnant women or women of child-bearing potential.

Contra-indications: Varbian should not be given to patients with serious ventricular arrhythmias.

Treatment of overdose: In the event of overdose,

the infusion should be discontinued. Symptomatic measures, combined if necessary with the cautious intravenous administration of a β -adrenoceptor blocking agent, should be employed.

Pharmaceutical precautions Recommended diluents are: sterile saline, Ringer's or 5.0% anhydrous glucose solution.

Legal category POM.

Package quantities Packs of 1 ampoule.

Further information Varbian has a half-life in plasma of about 2 hours. Varbian is excreted mainly via the kidneys and 60% of the dose is recovered in the urine as unchanged drug after intravenous administration in healthy subjects.

Product licence number 0008/0150

Rickmansworth, Herts WD3 1EZ

BARITOP* 100

Presentation White suspension containing Barium sulphate BP 100% w/v.

Uses X-ray contrast medium for radiography of the gastro-intestinal tract.

Dosage and administration The volume of Baritop 100 used will depend on the procedure and technique involved. The following dosages represent a basic guide to the quantities suitable for routine examinations:

Barium swallow	40–60 ml
Double-contrast examination of stomach and duodenum	100–150 ml
Follow-through examination of small bowel	150–300 ml
Barium enema	200–300 ml
	diluted with 600–900 ml water

Contra-indications, warnings, etc Suspected perforation of the gastro-intestinal tract. Caution should be exercised if the possibility of a lower small-bowel obstruction exists.

Pharmaceutical precautions Store in a warm place.

Legal category P.

Package quantities Sealed cans of 300 ml with 'ring-dill' opening.

Further information Baritop 100 contains carbon dioxide gas under pressure which is fully liberated at body temperature, providing a double contrast potential of its own for certain procedures. This unique property allied to excellent fluidity so that the suspension is capable of demonstrating exceptionally fine detail in the gastro-intestinal tract.

Product licence number 0603/5000.

BARITOP* EFFERVESCENT TABLETS

Presentation White tablets each containing:

Sodium Bicarbonate BP	35 mg
Calcium Carbonate BP	5 mg
Ascorbic Acid BP	35 mg
Methicone BPC	3 mg

Uses Supplementary gas-producing agent for double-contrast radiography of the gastro-intestinal tract.

Dosage and administration Twenty–thirty tablets for examination. The tablets should be swallowed with little water or barium suspension at the beginning of the examination. Ideally the tablets should be used in conjunction with a technique in which the stomach wall is 'washed' with the barium suspension by rolling the patient from side to side. The tablets should be swallowed as a single dose. Release of the gas will be proceeding while the patient is being turned from side to side and the full

volume will be available by the time the series of films is commenced.

The films should be taken as rapidly as possible after 'washing' the stomach wall, and it is essential for the patient to retain the gas in the stomach. The patients should, therefore, always be instructed to suppress eructation, at least until the series of films has been completed.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities Supplied in containers of 500 tablets.

Further information Baritop Effervescent Tablets contain a defoaming ingredient to prevent excessive bubble formation during release of the gas. This reduces the possibility of mucosal detail being obscured by barium foam.

Product licence number 0603/0014.

BARITOP* G POWDER

Presentation White granular powder containing 97% Barium Sulphate BP.

Uses X-ray contrast medium for radiography of the gastro-intestinal tract.

Dosage and administration Baritop G powder may be used to prepare barium suspensions of any required concentration.

It should be used when a concentration greater than that of the ready-made barium suspensions is required for visualisation of the upper GI tract, or when a slightly more viscous preparation is required for a barium swallow.

The powder is intended particularly for barium enemas, which may be mixed to the preferred concentration.

The following volumes and concentrations of suspension prepared from Baritop G Powder represent a basic guide for standard procedures, but may be varied according to individual preference.

	<i>Volume</i>	<i>Concentration</i>
Double contrast examination of stomach and duodenum	100–200 ml	100–150% w/v
Barium swallow	40–50 ml	130–150% w/v
Follow through examination of small bowel	300 ml	70–110% w/v
Barium enema (double contrast)	400–500 ml	70–150% w/v

Measure the quantity of water indicated on the pack to produce the required concentration, add the contents of the sachet, and stir or shake to give a smooth suspension.

Contra-indications, warnings, etc Suspected perforation of the gastro-intestinal tract.

Caution should be exercised if the possibility of a lower small-bowel obstruction exists.

Pharmaceutical precautions Store under dry conditions.

Legal category P.

Package quantities Sachets containing 200 g and 1 kg of powder.

Further information Nil.

Product licence number 0603/0020.

ELUDRIL* MOUTHWASH

Presentation Clear red solution containing:

Chlorhexidine digluconate	0.1% w/v
Chlorbutol	0.1% w/v
Chloroform	0.5% v/v

Uses For local treatment of the mouth and throat in conditions such as gingivitis, stomatitis, aphthous and dental ulcers, tonsillitis, pharyngitis and minor infections of the mouth and throat.

After operative or dental procedures in the mouth or throat, and for general oral hygiene.

Dosage and administration 10 ml in half a glass of lukewarm water used as a mouthwash or gargle three or four times a day.

Not suitable for use in infants.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottles of 90 ml and 500 ml.

Further information Nil.

Product licence number 0603/0012.

ELUDRIL* SPRAY

Presentation Clear solution in pressurised spray containing:

Chlorhexidine digluconate	0.05% w/v
Amethocaine hydrochloride	0.015% w/v

Uses For local treatment of the mouth and throat in conditions such as gingivitis, stomatitis, aphthous and dental ulcers, tonsillitis, pharyngitis and minor infection of the mouth and throat. As adjuvant treatment in Vincent's angina and oral thrush. Also after operative or dental procedures in the mouth or throat, and for general oral hygiene.

Dosage and administration For routine use spray the mouth and throat three or four times a day.

For treatment of acute conditions the spray may be used up to once an hour.

When swallowing is painful, spray the throat thoroughly a few minutes before eating.

The spray bottle should be shaken before use, and the end of the nozzle positioned just inside the mouth. Direct the spray towards the affected area of mouth or throat and activate the spray for two or three seconds.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Spray contains 55 ml of solution

Further information Nil.

Product licence number 0603/0013.

Wrexham

Clwyd LL 13 9PS

PP* STOMACH POWDER AND TABLETS

Presentation Available as a white powder and a plain tablet 12 mm in diameter.

Powder: Contains in 100 g:

alium Carbonate BP	37.82%
lagnesium Carbonate BP	37.50%
lagnesium Trisilicate BP	19.48%
ismuth Carbonate BP	2.00%
el. Alum. Hydrox. BP	3.00%
apaverine Hyd. BP	0.10%
omatropine Methyl Bromide USP	0.10%

Tablets: Each tablet contains:

alium Carbonate BP	180.5 mg
lagnesium Carbonate BP	195.0 mg
lagnesium Trisilicate BP	92.5 mg
ismuth Carbonate BP	12.5 mg
el. Alum. Hydrox. BP	15.0 mg
apaverine Hyd. BP	3.0 mg
omatropine Methyl Bromide USP	1.5 mg

Uses Dyspepsia, flatulence, nervous dyspepsia, excess acidity, heartburn biliousness, travel sickness, gastric and intestinal spasms, biliary colic, nausea and vomiting, peptic ulcer syndrome.

Dosage and administration *Powder:* 1 × 5 ml (teaspoonful) in water or milk three or four times a day.

Tablets: 1-2 tablets three or four times daily after meals.

Contra-indications, warnings, etc Glaucoma, myasthenia gravis.

Pharmaceutical precautions None.

Legal category POM.

Package quantities *Powder:* Cartons 100 g.

Tablets: Cartons of 50 and 250.

Further information Nil.

Product licence numbers

Powder 0183/5033

Tablets 0183/5013

ARDIACAP*

Presentation Slow-release capsules. Each capsule contains pentaerythritol tetranitrate (PETN) 30 mg. Blue/yellow capsule SC21 size 2 containing white and cream granules.

Uses Sustained relief in angina pectoris.

Dosage and administration One capsule to be taken every 12 hours.

Contra-indications, warnings, etc Glaucoma; should not be used in acute stages of myocardial infarction.

Pharmaceutical precautions None.

Overdosage: Treat by gastric lavage.

Legal category P.

Package quantities 30 and 200 capsules.

Further information Timed release base that provides for prolonged therapeutic effect for about 12 hours. Release pattern by diffusion.

Product licence number 0183/5018.

DEANASE*

Presentation Injectable pancreatic desoxyribonuclease as a lyophilised, white sterile, stable powder synergised with magnesium ions in vials of 1 mega and ½ mega.

Uses Haematoma, haemothorax, haematocele, mammary infections (acute puerperal mastitis) gravitational (varicose) ulcers, pressure or decubitus ulcers, other subacute or chronic ulcers, subacute cellulitis or thrombophlebitis, infected burns.

Tuberculous abscess of neck, dental abscess, intra-peritoneal abscess (subphrenic appendiceal, pelvic abscess), amoebic abscess of liver, osteomyelitis, actinomycosis, meningitis, bronchitis, unresolved pneumonia, chronic bronchial asthma, cystitis (purulent) or blood clots in bladder, virus infections (DNA) used in conjunction with cytotoxic drugs, antibiotic and radiation. In treatment of cancerous tumours. Lymphatic leukaemia.

Dosage and administration *Local therapy:* Local injection into a haematoma or superficial abscess cavity – 1,000,000 units in 2-3 ml of sterile isotonic saline. Intrathecal injection for meningitis – 1,000,000 units in 5 ml sterile isotonic saline repeated in two days as required.

Pre-urethral instillation for purulent cystitis or clots in the bladder – 1,000,000 units in 50 ml sterile water together with intramuscular systemic therapy. Aerosol inhalation spray for viscid sputum – 250,000 units in 10 ml sterile water repeated twice daily.

Systemic therapy: Is indicated in most of the above conditions and is given by intramuscular injection every second day, as required. An intramuscular injection of 1,000,000 units is effective over a period of 48 hours. In certain cases where an immediate effect is required it can be given intravenously.

Contra-indications, warnings, etc No untoward reactions have been observed in the use of this enzyme, even when injected in massive doses either systemically or locally, but possible sensitivity to beef protein should be borne in mind after a prolonged use.

Pharmaceutical precautions Store in a refrigerator at 4°C.

Under these conditions it will retain its activity for approximately two to three years. In solutions it loses its activity unless frozen. Solutions for injection should therefore be prepared at the time of use.

Legal category POM.

Package quantities $1 \times \frac{1}{4}$ million unit vial. 1×1 million unit vial + solvent.

Further information Deanaase hydrolyses highly polymerised desoxyribonucleic acid, which is chiefly responsible for the viscosity of purulent fibrinous exudates of which it forms from 30 to 70%. Its activity per unit weight is considerably greater than more commonly known enzymes.

Deanaase liquefies a) clotted blood and b) fibrinous and viscid purulent exudates following trauma or inflammation. These accumulations thereby become more readily absorbed or more fluid in consistency for easier aspiration or freer drainage. Deanaase readily removes the exudate so often resistant to the passage of antibiotics. While the absorption of a haematoma, superficial infection, or deep suppurative process may occur with Deanaase alone, resolution is often aided by preliminary antibiotic therapy and may require subsequent surgical intervention (e.g. aspiration or drainage).

Product licence number 0183/5028.

DEANASE* DC TABLETS

Presentation White, oval, enteric-coated tablet containing 10 mg of delta-chymotrypsin.

Uses In the control and reduction of inflammation in a variety of clinical conditions, e.g.:

Respiratory diseases – bronchitis, bronchiectasis, sinusitis, hay fever. Deanaase DC Oral also effectively reduces the viscosity of sputum in bronchial patients.

Trauma – contusions, haematomas, wounds, post-partum tissue reactions, sprains, fractures.

Phlebitis and thrombophlebitis.

Chronic ulcers – varicose, diabetic.

Inflammation of the eye – conjunctivitis, intra and extraocular trauma.

Inflammation following surgery – cellulitis, ulcerations, plastic surgery.

Dosage and administration Two tablets twice daily for three days and 1 tablet twice daily as maintenance dose.

Contra-indications, warnings, etc No known reaction reported, but protein sensitisation similar to pollen allergy cannot be entirely disregarded.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 16 and 200 tablets.

Further information Delta-chymotrypsin has approximately 50% greater activity than the more common alpha-chymotrypsin and therefore is markedly more effective in its anti-inflammatory action.

Product licence number 0183/5010.

DELIMON* TABLETS

Presentation Analgesic with marked anti-inflammatory activity. Flat, round, white tablet. Each tablet contains:

Morazone (2:3 Dimethyl-4- (3-methyl-2-phenyl morpho- linomethyl)- 1-phenylpyrazol-5-ONE hydrochloride)	0.15 g
Paracetamol	0.05 g

Uses The preparation is recommended in those more painful states, irrespective of cause, which are commonly treated with analgesics containing alkaloids, barbiturates or even opiates; also in influenza, headache (common colds, etc), menstrual pain, local pain (surgery), muscular or arthritic pain or rheumatism, and migraine, etc.

Dosage and administration Normally $\frac{1}{2}$ –1 tablet, if necessary several times daily; in cases of severe pain (injuries) correspondingly higher doses.

Contra-indications, warnings, etc None known.

Overdosage: Should be treated with gastric lavage followed by administration of L-methionine.

N.B. Patients may appear well for 2-3 days before developing signs of liver damage from paracetamol overdosage.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Tube of 12 tablets. Dispensing pack of 200 tablets.

Further information Contains no codeine or other alkaloid, no barbiturates, and no phenacetin or caffeine. Reduces the requirement of opiates. Well tolerated by mouth, and suitable for the symptomatic treatment of pain arising in gastro-intestinal tract and biliary apparatus.

Product licence number 0183/5011.

ENTEROMIDE* TABLETS

Presentation White tablet containing 500 mg of calcium 2-(4-(hydroxymethyl)-lureido-sulphonyl phenylcarbamoyl) benzoate. The approved name is calcium sulphaloxate. A round, flat tablet 12 mm in diameter.

Uses Summer diarrhoea in children and adults, bacterial dysentery, enteritis, colitis, food poisoning, pre-operative bowel sterilisation, 'Tourist Tummy', prophylactic against intestinal infections in tropical countries.

Dosage and administration *Adults and teenagers* 3×2 tablets daily.

Children: 3×1 tablet daily.

Infants: $3 \times \frac{1}{2}$ tablet daily.

In serious infections these doses can be doubled.

Contra-indications, warnings, etc Sulphonamide sensitivity. If administration is prolonged, white blood cell count must be checked.

Overdosage: Gastric lavage. High fluid intake.

Pharmaceutical precautions None.

Legal category POM.

Package quantities 25 and 200 tablets.

Further information Enteromide exerts both a bactericidal and bacteriostatic action. Approximately 95% of the ingested Enteromide remains unabsorbed in the intestine, thus exerting maximum concentration at the site of the infection.

Product licence number 0183/5008.

ERROCAP* CAPSULES

Presentation Capsules containing time-release granules. Each capsule contains:

Errorous fumarate 330 mg

(equiv. 110 mg elemental iron)

Vitamin B1 5 mg

Green/orange capsule size 0 containing brown and white granules.

Uses Ferrocap Capsules are recommended for treatment of anaemia from iron deficiency or blood loss, especially chronic haemorrhages, such as bleeding ulcers, haemorrhoids and some gynaecological disorders, and in all cases where dietary iron supplementation is desired.

Dosage and administration One capsule daily.

Contra-indications, warnings, etc None known.

Overdosage: Induce vomiting; gastric lavage. Parenteral administration of desferrioxamine mesylate 2 g and then leave 5 g of desferrioxamine in 100 ml of fluid in the stomach.

Pharmaceutical precautions None.

Legal category P.

Package quantities 20 and 200 capsules.

Further information Ferrocap releases its active principle by diffusion rather than disintegration. This patent process ensures constant release over four hours and is independent of pH, enzymatic activity and agitation.

Product licence number 0183/5014.

ERROCAP*-F 350 CAPSULES

Presentation Capsules containing time release granules. Each capsule contains:

Errorous fumarate

(equivalent 110 mg elemental iron)

330 mg

olic acid 350 mcg

Standard pink capsule size 0 containing brown, white and yellow granules.

Uses Ferrocap-F 350 Capsules are recommended in the management of anaemia in pregnancy. For folate deficiency and where iron intolerance is a factor.

Dosage and administration One capsule daily.

Contra-indications, warnings, etc None known.

Overdosage: Induce vomiting; gastric lavage. Parenteral administration of desferrioxamine mesylate 2 g and then leave 5 g of desferrioxamine in 100 ml of fluid in the stomach.

Pharmaceutical precautions None.

Legal category POM.

Package quantities 30 and 200 capsules.

Further information Ferrocap-F 350 releases its active principle by diffusion rather than disintegration. This patent process ensures constant release over four hours and is independent of pH, enzymatic activity and agitation.

Product licence number 0183/5017.

FLAR* CAPSULES

Presentation White opaque No. 2 hard gelatine capsule containing:

Selected lactic-ferments (see specification below) 5 billion.

Vitamin B₁ 5 mg

Vitamin B₂ (riboflavin) 0.5 mg

Vitamin B₆ (pyridoxine) 0.5 mg

Vitamin B₁₂ (cyanocobalamin) 5 mcg

PP (nicotinamide) 20 mg

Sodium pantothenate 7.5 mg

Inositol 20 mg

Folic acid 200 mcg

Liver extract from 20 g fresh liver

Inert excipient to 200 mg

The selected lactic ferments totalling 5 billion consist of *Streptococcus lactis* and *Lactobacillus acidophilus* taken from special strains that are resistant to the principal antibiotics and chemotherapeutics; such as penicillin, streptomycin, Chloramphenicol, erythromycin tetracyclines, aureomycin and sulphonamides, alone or in combination.

Uses Where lactic ferments are required.

Enteritis, gastro-enteritis, colitis, enterocolitis, dyspepsia, chronic constipation, intestinal putrefaction, diarrhoea, intestinal detoxication and certain diseases of the skin, such as urticaria, eczema and acne. Is most helpful where prolonged antibiotic treatment is necessary.

Dosage and administration *Children:* 1 capsule before each meal; in severe cases increase to 2.

Adults: 1-2 capsules before each meal; double dosage in severe cases.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities 10 and 200 capsules.

Further information In addition to said classical indications, and by virtue of its unique formulation, Flar is specifically suggested for the prevention and management of antibiotics or chemotherapeutic induced untoward side-effects, notably, states of weakness and adynamia, anaemia, atrophic mucosal lesions, black tongue, fissures, atrophic gastritis and nutritional deficiencies during treatment with antibiotics.

Product licence number 0183/5016.

FOSFOR* SYRUP

Presentation Phosphorylcolamine 5% w/v in a pink, raspberry-flavoured, sugar syrup.

Uses Promotes anabolic processes of metabolism and is therefore useful in convalescence from illness or surgery and in debilitating or wasting diseases. Improved metabolism leads to increased appetite and sense of well-being, helps counteract depression and lassitude and the return of normal sleep pattern, acute and chronic hepatitis.

Dosage and administration *Adults:* 4 × 5 ml dose (1 tablespoonful). Three times daily.

Children: 2 × 5 ml doses (1 dessertspoonful). Three times daily.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions None.

Legal category GSL.

Package quantities Bottles of 200 ml and 5 litres.

Further information Phosphorylcolamine is an amino acid with a high phosphorus content, easily assimilated, present as a natural product of cellular metabolism.

Product licence number 0183/5006.

FOSFOR* INJECTION

Presentation 10 ml ampoule, 25% w/v sodium phosphorylcolamine.

Uses Addition to parenteral drip in preventing post-operative body weight loss and enhancing the recovery of general well-being after surgery. In acute Liver disease, hepatic conditions and such symptoms as asthenia, anorexia and nausea.

Dosage and administration Single doses 20 ml (i.e. 5 gm) by intravenous injection. The injection to be administered daily or every other day for a period of two to three weeks, a course of 10-20 injections.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions Solutions of Calcium/magnesium salt can cause precipitation.

Legal category POM.

Package quantities Boxes 5 × 10 ml ampoules. Boxes 50 × 10 ml ampoules.

Further information Phosphorylcolamine is an amino acid with a high phosphorus content.

Product licence number 0183/5027.

Mn	22.600
mw	30.000
Relative viscosity at 37°C	1.9
Iso electric point	4.5 ± 0.3
pH value of the solution	7.4 ± 0.3
Colloid osmotic	465 mm H ₂ O
Pressure	35.2 mm Hg
Gel point	0°C

Uses Gelofusine increases the circulatory volume over a sustained period of time in cases of acute blood and fluid losses (circulatory collapse, hypovolemic shock). The prolonged expanding effect suffices in most cases to allow the resumption of normal blood regeneration. The gelatine is metabolised through proteolysis and eventually excreted. It has no antigenic properties and does not influence haemostasis.

Acute blood losses, treatment of surgical and traumatic shock (vascular atony), burns and in cases of hypovolemia due to transfer of plasma into tissues (damaged capillary walls caused by infectious diseases) or increased fluid loss (diarrhoea, vomiting). In critical blood losses (exceeding approx. one-third of the total blood volume) until whole blood can be administered.

Dosage and administration Control bleeding first. The quantity to be administered depends on requirement; and blood losses: administer by drip infusion. In urgent cases administer 500 ml within 10-15 minutes to adults and children weighing more than 25 kilos.

Contra-indications, warnings, etc Repeated minor bleeding, as in cases of gastric or duodenal ulcer, or similar chronic blood loss, calls for blood transfusions, as no hypovolemia is involved.

Pharmaceutical precautions Use only sterile infusion appliances, preferably disposable sets.

It is not recommended to mix with blood or plasma. Use only clear solutions from sealed containers.

Legal category POM.

Package quantities Infusion bottle of 500 ml. Pack of 10.

Further information Water-soluble, injectable medicament can if necessary be administered simultaneously with Gelofusine.

Preparations which should take immediate effect, such as analeptics, haemostatic agents, glucose solutions should be injected directly through the rubber section of the infusion tube. Preparations which are better tolerated in dilute form, such as gas gangrene antiserum, streptanin, circulatory agents, water-soluble vitamins should be injected into the solution through the rubber stopper mixed thoroughly.

Product licence number 0183/5025.

GELOFUSINE*

Presentation 4% Gelatin in Normal Saline.

Succinyl gelatin	20.0 g/500 ml
Na ⁺ content	77 mmol/500 ml
K ⁺ content max	0.2 mmol/500 ml
Mg ⁺⁺ content max	0.2 mmol/500 ml
Ca ⁺⁺ content max	0.2 mmol/500 ml
Cl ⁻ content max	62.5 mmol/500 ml

HEPACON* B FORTE INJECTION

Presentation 2 ml ampoules liver extract 15 mcgr B₁₂, vitamin B, pyrophosphate 50 mg, folic acid 2.5 mg

Uses Defective formation and maturation of red cell. Pernicious anaemia, etc.

Dosage and administration General tonic 2 ml every four days until red blood count is maintained. Anaemia intramuscular injection of 2 ml every day for the first

week, then decreasing doses every two weeks for several months. Permanent maintenance treatment is needed in pernicious anaemia.

Contra-indications, warnings, etc Sensitivity to protein.

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities Boxes 50 × 2 ml and 6 × 2 ml.

Further information In all conditions where a tonic is indicated. In pernicious anaemia. Secondary anaemia following severe diseases and loss of blood.

Product licence number 0183/5023.

HEPACON* B₁₂

Presentation 1 ml ampoules of vitamin B₁₂ 50, 100, 500 or 1,000 mcg per 1 ml.

Uses Pernicious anaemia, (Addisonian) anaemia, macrocytic anaemia of sprue (tropical and non-tropical), macrocytic nutritional anaemia, megaloblastic anaemia of infancy (certain cases), neurological symptoms of pernicious anaemia and neuropathies.

Dosage and administration *In anaemia:* Therapy is initiated with injections of 15-30 mcg once or twice per week, depending upon the nature and severity of the case and the response of the patient. For maintenance, injections of 15-30 mcg may be given at intervals of 15-30 days, or as indicated.

In neurological disturbances: 1,000 mcg, daily decreasing as improvement is noted, or as determined by the physician.

Contra-indications, warnings, etc None.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Boxes 6 × 1 ml, 50, 100, 500 or 1,000 mcg.

Further information Nil.

Product licence number 0183/5022.

HEPACON* LIVER EXTRACT

Presentation Ampoules 2 ml in strengths of 5, 10, 15, 50 or 1,000 mcg B₁₂.

Uses Pernicious anaemia, tropical sprue, pellagra, tropical macrocytic anaemia, anaemia of pregnancy, fish tapeworm anaemia, gastric carcinoma or resection, hepatitis cirrhosis and chronic intestinal disease with protracted diarrhoea. Convalescence and general weakness.

Dosage and administration 1/2 ampoules administered intramuscularly.

Contra-indications, warnings, etc Possible protein sensitivity.

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities Boxes 50 × 2 ml and 6 × 2 ml.

Further information Nil.

Product licence number 0183/5019.

HEPACON*-PLEX VITAMIN B COMPLEX

Presentation Ampoules 2 ml

Vitamin B ₁	100 mg
Vitamin B ₂	2 mg
Vitamin B ₆	5 mg
Vitamin B ₁₂	8 mcg
Nicotinamide	150 mg
Calcium pantothenate	10 mg

Uses Vitamin B complex deficiencies, neuropsychiatric diseases, gastro-intestinal diseases, cutaneous diseases of nutritional origin, etc.

Dosage and administration 1/2 ampoules intramuscularly as required.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities Boxes 50 × 2 ml and 6 × 2 ml.

Further information Nil.

Product licence number 0183/5021.

MINAMINO* COMPOUND SYRUP

Presentation Pleasant palatable syrup. Each 100 ml contains:

Biologicals:

Liver extract from	70 g fresh liver
Spleen extract from	15 g fresh spleen
Gastric mucosa extract from	7 g fresh gastric mucosa

Vitamins:

Vitamin B ₁	300 mg
Vitamin B ₂	40 mg
Vitamin B ₆	35 mg
Vitamin PP	400 mg
Vitamin B ₁₂	100 mcg

Amino acids: 2,000 mg of which the following are present. Typical analysis: histidine 175 mg, Arginine 140 mg, methionine 73 mg, tryptophane 84 mg; threonine 136 mg, tyrosine 150 mg, glutamic acid 207 mg, aspartic acid 46 mg, proline 14 mg, glycine 53 mg; alanine 85 mg, valine 102 mg, phenylalanine 153 mg, isoleucine 74 mg, leucine 306 mg, lysine 194 mg.

Minerals:

Iron citrate	410 mg
Manganese sulphate	1.7 mg
Copper sulphate	2.8 mg
Flavoured excipient to	100 ml

Uses As a vitamin and mineral supplement in geriatrics and paediatrics, delayed growth in children, during convalescence following surgery or infectious diseases and recovery from burns, influenza and colds. During corticosteroid therapy, physical and mental exhaustion. During pregnancy and lactation.

Dosage and administration *Children:* 2 × 5 ml in water three times daily.

Adults: 4 × 5 ml three times daily.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Bottles of 100 ml and 500 ml.

Further information Nil.

Product licence number 0183/5003.

NU-K*

Presentation Pale Blue opaque hard gelatin capsule size 0 containing 600 mg potassium chloride BP equiv. to 315 mg K or approx. 8 mEq of K⁺, in slow release granules.

Uses Treatment or prevention of potassium depletion or hypokalaemia from any cause eg. prolonged treatment with diuretics (especially thiazides or frusemide) or corticosteroids, cirrhosis, malabsorption, conditions associated with chronic diarrhoea.

Dosage and administration Dosage depends on the degree of potassium depletion. In most patients one to six capsules per day, preferably one at a time after food. It should be remembered that the degree of depletion of tissue potassium is not accurately reflected by the serum potassium level.

Contra-indications, warnings, etc Obstruction of the alimentary tract, advanced renal failure and conditions associated with hyperkalaemia, such as untreated Addison's disease, are all contra-indications. The risk of gastro-intestinal irritation or ulceration inherent in oral administration of potassium preparations is minimised by the mode of action of the time release granules, but the occurrence of symptoms of obstruction or ulceration indicates withdrawal of oral potassium preparations. In the presence of impaired renal function, or when potassium-sparing diuretics are used, the serum potassium level should be monitored to adjust dosage.

Overdosage: Treatment should be directed to the removal of ingested material by induced emesis or gastric lavage as appropriate. Fluid intake and output should be monitored and measures directed to the restoration of fluid and electrolyte balance. Measures to combat hypotension should be taken if required.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities 500 capsules.

Further information Nil.

Product licence number 0183/0018.

OTOTRIPS* EAR DROPS

Presentation Vial with dropper containing:

Polymixin B sulphate	16,000 i.u.
Bacitracin	20,000 i.u.
Crystalline trypsin	25,000 NF. units
Sodium chloride	27 mg
Gelatin	15 mg

One ampoule distilled water

Uses All forms of bacterial ear infections. Acute inflammatory conditions of middle and external ear.

Dosage and administration Three to four drops instilled into ear three times daily.

Contra-indications, warnings, etc Allergy to Polymixin or Bacitracin

Pharmaceutical precautions Store in cool place.

Legal category POM.

Package quantities One box with vial, dropper and ampoule solvent.

Further information Nil.

Product licence number 0183/5000.

PLEX-HORMONE* INJECTION

Presentation A sterile solution for injection. Each 1 ml contains:

Testosterone propionate	20.0 mg
Desoxycorticosterone acetate	0.5 mg
Oestradiol benzoate	0.1 mg
Tocopheryl acetate (vitamin E)	20.0 mg

Uses Deficiency of male hormone – decreased potency; male androgen deficiency; pituitary deficiency.

Dosage and administration 2-3 injections weekly for two weeks followed by 1 injection weekly for three weeks. Maintenance dosage: 1 injection weekly.

Contra-indications, warnings, etc Contra-indicated in prostatic carcinoma, and in ischaemic heart disease.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities 6 × 1 ml box.

Further information Nil.

Product licence number 0183/5024.

PLEX-HORMONE* TABLETS

Presentation Each tablet contains:

Methyl testosterone	5 mg
Desoxycorticosterone acetate	0.5 mg
Ethinyl oestradiol	0.002 mg
Tocopheryl acetate (vitamin E)	5 mg

Uses Deficiency of male hormone – decreased potency; male androgen deficiency; pituitary deficiency.

Dosage and administration Should a rapid and intensive effect be needed for only a short period, 4-5

tablets daily for 10 days will be sufficient. The same course to be repeated when necessary, leaving at least 10-day intervals between courses.

Should an intensive action be required over a prolonged period, begin with 4–5 tablets daily for a fortnight (60–70 tablets) followed by lower maintenance dosage.

Contra-indications, warnings, etc Contra-indicated in prostatic carcinoma, and in ischaemic heart disease.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Carton of 24 tablets.

Further information Nil.

Product licence number 0183/5020.

PROPER-MYL*

Presentation 1 box containing 10 ampoules and solvent. Each ampoule contains 10 million Lyophilised yeast cells equivalent to approximately 10 micrograms of dry protein.

Uses A properdin forming agent prepared from selected yeast, known to produce significant increases in the Gamma globulins associated with antibody functions and responses.

Multiple Sclerosis.

Neoplasm.

Radiation sickness and Infectious Diseases.

Dosage and administration Graduated dosage as per instruction leaflet.

Contra-indications, warnings, etc No contra-indications known.

Pharmaceutical precautions None.

Legal category POM.

Package quantities 1 box containing: 10 ampoules powder 'Proper-Myl' with 10 ampoules solvent.

Further information Nil.

Product licence number 0183/5001.

TACHOSTYPTAN* INJECTABLE HAEMOSTAT

Presentation Each 5 ml ampoule of cream coloured colloidal solution contains 2% w/v standardised thromboplastin extracted from brain tissue.

Uses Tachostyptan is indicated in not only the treatment but in the prophylaxis of haemorrhage arising from many medical and surgical conditions. It is of particular value before and after operations associated with oozing surfaces.

Medical: Blood diatheses associated with bleeding, e.g. leukaemia, Henoch's purpura, hypoprothrombinaemia, etc. Haematemesis or melaena due to oesophagitis, oesophageal varices, peptic ulcer, gastric erosion, ulcerative colitis, polyposis, carcinoma of alimentary tract, etc. Haemoptysis due to various causes. Acute pulmonary edema. Bleeding following administration of coumarin group of drugs during anticoagulant therapy.

Surgery: Especially operative procedures associated with much tissue trauma or oozing surfaces. Haemorrhage from ulcerating malignant surface lesions.

Dosage and administration The optimal therapeutic effect is obtained by slow intravenous injection. The haemostatic effect begins after several minutes and decreases gradually after four to five hours. Tachostyptan can also be injected locally into the tissue (e.g. tonsillectomy) or administered locally by swab in haemorrhage of easily accessible wounds. Especially advantageous is the combined simultaneous dosage by parenteral and local administration. It is difficult to be precise on dosage, single and daily dosage depend on the severity of haemorrhage. In general 1–2 × 5 ml ampoules are injected at intervals of three to four hours up to 12 ampoules. In severe haemorrhage the administration in an intravenous drip has been successful, 12 ampoules in 1,000 ml normal saline over a period of six hours. As a prophylactic measure in patients in whom post-operative bleeding is suspected 1–2 ampoules should be given prior to surgery. This is now routine practice with some surgeons. Even if large doses of Tachostyptan are given there is no danger of intravascular thrombosis. It can also be used locally for superficial bleeding surfaces. In cases of hypoprothrombinaemia and dicoumaril overdosage, it is administered with Vitamin K therapy.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Boxes of 6 × 5 ml ampoules. Hospital packs of 50 × 5 ml ampoules.

Further information The arrest of bleeding (haemostasis) is a complex physiochemical process which depends on two main factors: 1) clotting of the blood: 2) capillary retraction.

Tachostyptan acts in the same way as thromboplastin (thrombokinase) by shortening the clotting time. This action, however, is exercised only at the point of haemorrhage. It does not lead to thrombosis in the intravascular system. At the same time, it appears to have a local action on the capillaries by retracting them and reducing their permeability.

Product licence number 0183/5029.

UROMIDE* DRAGEES

Presentation A specifically synthesised sulphonamide for urinary tract infections. With an anaesthetic for the relief of pain. Each dragee of Uromide contains:

Sulphacarbamide	500 mg
Phenazopyridine hydrochloride	50 mg

Uses Infections of the descending urinary tract accompanied by pain, urethral burning or micturition difficulties (urethritis, cystitis, cystopyelitis). Infection prophylaxis in cases of instrumentation (catheterisation, cystoscopy). Follow-up treatment after urological operations.

Dosage and administration *Adults and teenagers:* 2 dragees (tablets) three times daily.

Children: 1 dragee (tablet) three times daily.

Infants: ½ dragee three times daily.

The unique shaped dragee is placed in the mouth and swallowed with a little water.

Contra-indications, warnings, etc The phenazopyridine hydrochloride content of the product demands that a daily dose of ten dragees should not be exceeded. Sulphonamide sensitivity. (Side effects common to all sulphonamides, i.e. nausea, depression, headaches, skin-rash.)

Pharmaceutical precautions None.

Overdosage: Wash out stomach. Maintain high fluid intake for four days, and give potassium citrate.

Legal category POM.

Package quantities 25 and 200 dragees.

Further information The rapid resorption and high renal clearance figure (approx. 84-96 ccm/min) of sulfanylcabamide sulphacarbamide) account for the fact that about half the quantity resorbed will be present in the urine after periods of less than two to three hours. Due to its exceptionally good solubility in any pH range, crystallisation in the lower urinary tract is avoided, and increased intake of liquid or pH adjustment are unnecessary. The product is extremely well tolerated and no adverse conditions have been reported.

Product licence number 0183/5012.

**Trade Mark*

Cox Continental Limited
Whiddon Valley
Barnstaple
North Devon EX32 8NS

ANTOIN*

Presentation White, uncoated, dispersible, aspirin compound tablets, impressed one side 'Antoin' and a division line on the reverse, each tablet containing:

Codeine Phosphate BP	5 mg
Aspirin BP	400 mg
Caffeine Citrate BPC 1959	15 mg
Calcium Carbonate BP	130 mg
Anhydrous Citric Acid BP	40 mg

Uses Antoin has analgesic and anti-inflammatory actions. It is indicated for all mild to moderate pain conditions such as headache, dental pain and that resulting from dysmenorrhoea, and as an anti-inflammatory/analgesic in the treatment of rheumatic and associated conditions.

Dosage and administration *Adults:* 1-2 tablets dissolved in water, three to four times a day; maximum daily dose is 10 tablets.

Children: Not recommended for children.

Contra-indications, warnings, etc Antoin should not be given to patients with a known idiosyncrasy to aspirin or those suffering from active peptic ulceration or haemophilia.

Special precautions: There is clinical and epidemiological evidence of the safety of aspirin in pregnancy, but it may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term.

Warnings and adverse effects: Aspirin may precipitate ironchospasm, and induce attacks of asthma in susceptible subjects; it may also induce gastro-intestinal haemorrhage, occasionally major.

Aspirin may enhance the activity of coumarin anticoagulants and oral hypoglycaemic agents. The activity of methotrexate may be markedly enhanced and its toxicity increased. The toxicity of sulphonamides may also be increased. Aspirin diminishes the effects of uricosuric agents such as probenecid and sulphinpyrazone.

Overdosage: Normal procedures for overdosage with aspirin and codeine should be followed. Gastric lavage and forced alkaline diuresis should be used if appropriate.

Pharmaceutical precautions Antoin tablets should be stored in a tightly-closed container, in a cool dry place and protected from the light.

Legal category P.

Package quantities Antoin is available in containers of 20, 50 and 250.

Further information Nil.

Product licence number 1866/5001.

COBADEX*

Presentation Cobadex Cream is available in two

strengths containing Hydrocortisone BP 0.5% w/w or Hydrocortisone BP 1.0% w/w; and Dimethicone 350 BPC 20% w/w.

Uses Cobadex Cream is formulated to include volatile and skin-penetrating solvents. This enables the hydrocortisone to be carried into the skin by the organic solvent vehicle, and at the same time evaporation of water will take place from the external surface of the cream, leaving a water-repellent silicone film in contact with the air. Cobadex is indicated, therefore, in all steroid responsive dermatoses wherever water, soap, chemicals, etc. cause irritation, e.g. contact dermatitis (especially of hands and body), pruritus ani and pruritus vulvae.

Dosage and administration A thin layer of cream should be applied to the affected area two or three times daily.

Contra-indications, warnings, etc The cream should not be used on raw, weeping surfaces because it tends to hold back any exudate. The area of skin around the eye should be avoided.

Long-term continuous topical steroid therapy should be avoided in infants, since adrenal suppression may occur, even without occlusion.

Special precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Adverse reactions: Discontinue treatment should sensitisation occur.

Pharmaceutical precautions Cobadex should be stored in a cool dry place; avoid freezing.

Legal category POM.

Package quantities Both strengths of Cobadex are available in 20 g tubes.

Further information Nil.

Product licence numbers

0.5% cream	1866/5004
1% cream	1866/5005

COBADEX-NYSTATIN*

Presentation Cobadex-Nystatin is a pale yellow ointment containing Nystatin BP 100,000 i.u./g. Hydrocortisone BP 1% w/w, Dimethicone 350 BPC 20% w/w, Benzalkonium Chloride BP 0.2% w/w.

Uses Cobadex-Nystatin is indicated in all steroid responsive dermatoses, including eczema, intertrigo, seborrhoeic dermatitis, household and industrial dermatitis and pruritus ani and vulvae, and in all other skin irritations requiring steroid therapy in which *Candida albicans* is a factor.

Dosage and administration A thin layer of ointment sufficient to cover the affected area should be applied two or three times daily until the lesion is healed.

Contra-indications, warnings, etc

Contra-indications: The ointment should not be used on raw, weeping surfaces because it tends to hold back any exudate. The area of skin around the eye should be avoided.

Special precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Adverse reactions: Discontinue treatment should sensitisation occur.

Pharmaceutical precautions Cobadex-Nystatin should be stored in a cool dry place; avoid freezing.

Legal category POM.

Package quantities Tubes of 20 g.

Further information Nil.

Product licence number 1866/0005.

CO-FEROL*

Presentation Red, sugar-coated tablets each containing:

Ferrous fumarate	120 mg (40 mg elemental iron)
Folic acid	200 mcg

Uses Normal pregnancy – as a prophylactic throughout the pregnancy. Co-ferol is not intended for the treatment of megaloblastic anaemia, though it is adequate for the treatment of mild degrees of iron-deficiency anaemia.

Dosage and administration One tablet twice daily.

Contra-indications, warnings, etc Contra-indicated in megaloblastic anaemia due to B₁₂ deficiency.

Special precautions: Keep away from children.

Co-ferol does not obviate the need for routine blood examination in late pregnancy. Co-ferol should not be continued after pregnancy has ended.

Adverse reactions: Very occasional gastro-intestinal upset.

Overdosage: Emesis should be induced, followed by intra-muscular injection of 2 g desferrioxamine mesylate in 2–3 ml water for injections. Gastric lavage is also required. Milk or 5% sodium bicarbonate may be given in the meantime. A solution of 5 g desferrioxamine mesylate in 50–100 ml water may be left in the stomach or 300 ml of 1–5% sodium bicarbonate if desferrioxamine is unavailable. Fluid maintenance is essential.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities 100 and 1,000 packs, also 5,000 hospital pack.

Further information Nil.

Product licence number 1866/5006.

COSALGESIC* ▼

Presentation Oval shaped tablets of approximate length 14 mm and breadth 8.5 mm containing dextro-

propoxyphene hydrochloride BP 32.5 mg, and paracetamol BP 325 mg. The tablets bear the letters CC impressed on one surface and COX on the other surface. The tablets are white film-coated.

Uses Analgesic. For the relief of mild to moderate pain.

Dosage and administration Two tablets, three or four times daily. (*Adults only*).

Contra-indications, warnings, etc

Contra-indications: Hyper-sensitivity to dextropropoxyphene or paracetamol.

Precautions: The safety of dextropropoxyphene has not been established in pregnancy.

Warnings and adverse effects: Because Cosalgescic is an analgesic with CNS depressing properties, it should be used with great caution in patients taking other CNS depressants, including alcohol.

The patient should be advised that alcohol should be avoided when taking Cosalgescic.

Care should be exercised in prescribing Cosalgescic for patients with a personality or other psychological disorder.

An overdosage of paracetamol can cause hepatic necrosis.

Dextropropoxyphene may impair the mental and/or the physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery.

Tolerance: Psychological and physical dependence may occur rarely.

Side-effects: Dizziness, drowsiness, headache, nausea and vomiting are all possible side-effects and appear to be more likely to occur in ambulatory than in non-ambulatory patients therefore alleviation of these side-effects can be sometimes produced by lying down after taking the tablets.

Other reported side-effects are constipation, abdominal pain, skin rashes, euphoria, lightheadedness and minor visual disturbances.

Overdosage: A chronic ingestion of dextropropoxyphene in doses exceeding 720 mg as base (equivalent to 780 mg as hydrochloride) per day has caused toxic psychoses and convulsions.

The symptoms of acute toxicity may be rapid in onset with the danger of respiratory arrest. Symptoms exhibited are similar to those experienced with morphine and other narcotics. These are respiratory depression, (a decrease in respiratory rate and/or tidal volume) Cheyne-Stokes respiration, cyanosis, extreme somnolence (progressing to stupor or coma), constriction of pupil, circulatory collapse and other characteristic symptoms of narcotic poisoning. Cardiac arrhythmias and pulmonary oedema have been reported.

Fatalities due to apnoea and cardiac arrest have occurred on rare occasions.

Treatment of overdosage: Firstly, adequate respiratory exchange should be re-established by provision of an adequate airway and assisted or controlled ventilation. The narcotic antagonist naloxone is a specific antidote against the respiratory depression produced by dextropropoxyphene. An appropriate dose of this antagonist should be administered, preferably by the intra-venous route, simultaneously with efforts at respiratory resuscitation. Repeated doses of the antagonist may be necessary over a prolonged period due to the slow elimination of dextropropoxyphene.

In addition to the use of a narcotic antagonist, the

patient may require careful titration with an anti-convulsant to control seizures. Analeptic drugs (e.g. caffeine or amphetamines) should not be used because of their tendency to precipitate convulsions.

Early assessment of the severity of paracetamol poisoning by measurement of plasma paracetamol levels is essential if treatment, which should be instituted within ten hours of ingestion, is to be effective. Present evidence suggests that cysteamine, methionine or N-acetylcysteine given within this period are effective in greatly reducing the toxic effects of paracetamol. Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Gastric lavage may be helpful. Activated charcoal can absorb a significant amount of ingested dextropropoxyphene.

Pharmaceutical precautions No special requirements. Advisable to store in airtight containers and in a cool, dry place.

Legal category POM.

Package quantities Cartons of 100 tablets containing 10 blisters of 10 tablets. Special Hospital Pack containing 20 bottles of 50 tablets.

Further information Nil.

Product licence number 1866/0007.

CYCLOGEST*

Presentation White suppositories, suitable for vaginal or rectal insertion. Each 1.85 g suppository contains either 200 mg or 400 mg Progesterone.

Uses Treatment of Premenstrual Syndrome, including Premenstrual tension and depression, Premenstrual Eclampsia, Premenstrual Migraine and Premenstrual Asthma. Treatment of Puerperal depression.

Relief of Toxaemic symptoms in pregnancy.

Dosage and administration 200 mg daily to 400 mg twice a day, by vaginal or rectal insertion. For Premenstrual Syndrome commence treatment on day 14 of menstrual cycle and continue treatment until onset of menstruation. If symptoms are present at ovulation commence treatment on day 12.

Contra-indications, warnings, etc There are no known contra-indications.

Menstruation may occur earlier than expected, or more rarely, menstruation may be delayed. There is a wide margin of safety with Cyclogest Suppositories, but overdosage may produce euphoria or dysmenorrhoea.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities

Packs of 12 Suppositories 200 mg

Packs of 12 Suppositories 400 mg

G500* TABLETS

Presentation Orange coloured, enteric film coated, circular, biconvex tablets with a characteristic odour. Each tablet contains:

Hexamine Mandelate (Methanamine Mandelate USP)	250 mg
dl Methionine USP	250 mg

Uses *Mode of action:* Hexamine mandelate is a bacteriostatic compound, active against those Gram-negative and Gram-positive bacteria which most usually cause urinary tract infections. In the acidic urine produced by the methionine contained in G500 tablets, the hexamine mandelate dissociates to hexamine and mandelic acid. Mandelic acid is a bacteriostatic agent active against a range of urinary tract pathogens. Hexamine is subsequently hydrolysed to the bactericide formaldehyde in acidic conditions.

Hexamine mandelate is well absorbed from the gastrointestinal tract and side effects rarely develop. The enteric coated tablet protects the hexamine mandelate from premature hydrolysis in the gastric fluid by releasing the drug only in the alkaline environment of the intestine.

G500 tablets are indicated in the treatment and prophylaxis of urinary tract infections due to *Escherichia coli*, *Pseudomonas aeruginosa*, *Aerobacter aerogenes*, *Klebsiella pneumoniae*, and some *Staphylococcus* and *Streptococcus* species. It may also be effective against some protozoal infections. After acute infection successfully treated with antibiotics, G500 tablets may be used to prevent re-infection.

Chronic urinary infections and recurrent cystitis: G500 tablets may be used for long term therapy in chronic urinary tract infections and recurrent cystitis. The development of resistant organisms has not been reported.

Asymptomatic bacteriuria: may be treated with G500 tablets.

Prophylaxis and suppression of infection: G500 tablets may be used to suppress infection. Given prophylactically, G500 tablets may prevent the establishment of urinary tract infection due to instrumental procedures.

G500 tablets are particularly useful in long term treatment as bacterial resistance does not appear to develop.

G500 tablets are NOT recommended for the treatment of acute urinary tract infections which should be treated with an appropriate antibiotic, except where resistance to other antimicrobial agents is found.

Dosage and administration

Adults and children over 12 years: Treatment should commence with two tablets four times daily for one week. Urinary pH should be tested by means of a suitable test paper or reagent, and the dosage adjusted until the urine reaches pH 5. The test is best carried out on early morning urine. The maximum dose should not exceed sixteen tablets daily in four divided doses.

Children 6-12 years: One to four tablets daily (normally 14 mg hexamine mandelate per kg body weight). Check the urinary pH daily and adjust the dosage as necessary to give a urinary pH of about 5.

Children under 6 years: Because G500 tablets should not be broken or crushed, they are not recommended for children under 6 years.

As with most enteric coated preparations, G500 tablets are best given with or after food, and should be SWALLOWED WHOLE, NOT CHEWED OR CRUSHED,

in order to obtain the full therapeutic effect. Simultaneous administration of ANTACIDS SHOULD BE AVOIDED in order to prevent premature release of the active ingredients.

Where urea splitting bacteria are present in the urine, additional acidification may be necessary. Up to 2 g of ascorbic acid, *as the free acid*, may be given daily for this purpose, which must be done under medical supervision, in accordance with confirmation of acidification by laboratory tests. If the urine cannot be acidified, treatment must be discontinued.

Contra-indications, warnings, etc

Side effects: Occasionally skin rashes may occur. Pyuria is commonly observed. The urinary concentration of formaldehyde produced may give rise to painful and frequent micturition, haematuria and irritation of the bladder. The side effects are reversible when G500 tablets are withdrawn. (See Overdosage below).

Contra indications: G500 tablets should not be given to patients with hepatic insufficiency, severe dehydration, metabolic acidosis or renal impairment.

G500 tablets should not be given concurrently with sulphonamides (including Co-Trimoxazole) as crystalluria may occur. A suitable gap in treatment should occur if administering G500 tablets after a long acting sulphonamide such as sulfametopyrazine or sulphamethoxy-pyridazine. G500 should not be given with alkalinizing agents, potassium citrate, sodium bicarbonate, antacids etc.

G500 tablets are contra-indicated in patients receiving mono-amine oxidase inhibitors as the methionine content may cause symptoms of intoxication.

Overdosage: Vomiting and haematuria may occur. Bladder irritation caused by the production of acidic urine may be treated by the administration of copious amounts of water and a suitable alkalinizing agent e.g. potassium citrate, sodium bicarbonate. Because the product is enteric coated, this may lead to prolonged effect on urinary pH. It is therefore advisable to monitor urinary pH for a reasonable period.

Pharmaceutical precautions G500 tablets should be stored in a well-closed container.

Legal category P.

Package quantities 500 tablets.

Further information Methionine is a sulphur containing amino acid, which is an essential dietary constituent.

G500 tablets normally have the characteristic odour of methionine.

Administration of G500 tablets may interfere with tests to determine 17-hydroxy-corticosteroids, oestrogens or catecholamines in the urine.

Administration of G500 tablets may cause an increase in urinary ammonium, calcium, magnesium and phosphate.

Product licence number 1511/5900.

Product Licence Holder: Secretary of State for Social Services, Department of Health and Social Security, Scientific and Technical Branch 4A.

KLOREF[®]

Presentation White, effervescent, flavoured tablets equivalent to 500 mg potassium chloride (6.7 mmol K⁺ and 6.7 mmol Cl⁻). Each tablet contains:

Betaine Hydrochloride BPC 1949	740 mg
Potassium Bicarbonate BPC	455 mg
Potassium Chloride BP	140 mg
Potassium Benzoate	50 mg

Uses Kloref is indicated in all cases of potassium depletion resulting from intensive or prolonged diuretic therapy. Corticosteroid therapy. Use of carbenoxolone sodium. Patients at special risk are those on a low-salt diet and those receiving digitalis. A lack of cellular potassium in the latter can increase the toxic effect of digitalis.

Potassium deficiency resulting from an inadequate potassium dietary intake – here the elderly population are a special risk. Other indications are advanced hepatic cirrhosis, chronic renal disease, Cushing's syndrome, diabetic ketosis and in conditions requiring potassium supplementation due to prolonged or chronic diarrhoea or vomiting.

Dosage and administration In most cases 1–2 tablets three times daily (20–40 mmol K⁺ and Cl⁻). A few patients may need considerably bigger doses. Each tablet should be fully dissolved in at least 100 ml of cold or refrigerated water before drinking.

The tablets themselves should not be swallowed.

Contra-indications, warnings, etc Contra-indicated in hyperchloraemia; renal tubular or metabolic acidosis.

Special precautions: Cautious administration required in cases of chronic renal disease.

Overdosage: Hyperkalaemia. Poisoning is usually minimal below 6.5 mmol/l, moderate between 6.5 and 8 mmol/l and severe above that level. The absolute toxicity is governed by both pH and associated sodium levels. Hyperkalaemic symptoms and particularly the ECG effects may be transiently controlled by calcium gluconate, administration of glucose or glucose and insulin, sodium bicarbonate or hypertonic sodium infusions, cation exchange resins or by haemodialysis and peritoneal dialysis. Caution should be exercised in patients who are digitalised and who may experience acute digitalis intoxication in the course of potassium removal.

Pharmaceutical precautions Kloref Tablets should be stored in a cool dry place. Avoid storing at temperatures in excess of 25°C.

Legal category P.

Package quantities Kloref is available in packs of 100, also available in containers of 1,000 for supply to hospitals only.

Further information The addition of water to each tablet brings about a reaction between the betaine hydrochloride and potassium bicarbonate which with the additional potassium chloride will provide the equivalent of 500 mg potassium chloride (6.7 mmol K⁺ and 6.7 mmol Cl⁻) in solution. Effervescence results from the liberation of carbon dioxide.

Betaine is a naturally occurring substance found in beet, and is metabolised by the body.

Product licence number 1866/5009.

KLOREF-S[®]

Presentation Kloref-S is presented as effervescent granules, packed in individual sachets to contain the

equivalent of 1.50 g potassium chloride. Each sachet contains:

Betaine Hydrochloride BPC 1949	2.07 g
Potassium Bicarbonate BPC	1.35 g
Potassium Chloride BP	0.5 g

Uses Kloref-S is indicated in all cases of potassium depletion resulting from intensive or prolonged diuretic therapy. Corticosteroid therapy. Use of carbenoxolone sodium. Patients at special risk are those on a low salt diet and those receiving digitalis. A lack of cellular potassium in the latter can increase the toxic effect of digitalis.

Potassium deficiency resulting from an inadequate potassium dietary intake; here the elderly population are a special risk. Other indications are advanced hepatic cirrhosis, chronic renal disease, Cushing's syndrome, diabetic ketosis and in conditions requiring potassium supplementation due to prolonged or chronic diarrhoea or vomiting.

Dosage and administration In most cases 1 or 2 sachets daily (20–40 mmol K⁺ and Cl⁻) preferably after meals. A few patients may need considerably bigger doses. Each sachet should be dissolved in at least 200 ml of cold water.

Contra-indications, warnings, etc Contra-indicated in hyperchloraemia, renal tubular or metabolic acidosis.

Special precautions: Cautious administration required in cases of chronic renal disease.

Overdosage: Hyperkalaemia. Poisoning is usually minimal below 6.5 mmol/l, moderate between 6.5 and 8 mmol/l and severe above that level. The absolute toxicity is governed by both pH and associated sodium levels. Hyperkalaemic symptoms and particularly the ECG effects, may be transiently controlled by calcium gluconate, administration of glucose or glucose and insulin, sodium bicarbonate or hypertonic sodium infusions, cation exchange resins or by haemodialysis and peritoneal dialysis. Caution should be exercised in patients who are digitalised and who may experience acute digitalis intoxication in the course of potassium removal.

Pharmaceutical precautions Kloref-S Sachets should be stored in a cool dry place. Avoid storing at temperatures in excess of 25°C.

Legal category P.

Package quantities Kloref-S is available in boxes of 30 sachets.

Further information The addition of water to each sachet brings about a reaction between the betaine hydrochloride and potassium bicarbonate which with the additional potassium chloride will provide the equivalent of 1.5 g potassium chloride (20 mmol K⁺ and 20 mmol Cl⁻) in solution. Effervescence results from the liberation of carbon dioxide.

Betaine is a naturally occurring substance found in beet, and is metabolised by the body.

Product licence number 1866/0001.

MYOLGIN*

Presentation White, uncoated, dispersible, aspirin, paracetamol and codeine tablets impressed one side

'Myolgin' and a division line on the reverse, each tablet containing:

Codeine Phosphate BP	5 mg
Aspirin BP	200 mg
Paracetamol BP	200 mg
Citric Acid BP	15 mg
Calcium Carbonate BP	60 mg
Caffeine Citrate BPC 1954	15 mg

Uses Myolgin has analgesic and anti-inflammatory actions. It is indicated for all mild to moderate pain conditions such as headache, dental pain and that resulting from dysmenorrhoea and as an anti-inflammatory/analgesic in the treatment of rheumatic and associated conditions.

Dosage and administration One or two tablets dissolved in water, three to four times a day; maximum daily dose is 16 tablets. Myolgin should not be given to children.

Contra-indications, warnings, etc Myolgin should not be given to patients with a known idiosyncrasy to either aspirin or paracetamol; or those suffering from active peptic ulceration or haemophilia.

Special precautions: There is clinical and epidemiological evidence of the safety of aspirin in pregnancy, but it may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term.

Warnings and adverse effects: Aspirin may precipitate bronchospasm, and induce attacks of asthma in susceptible subjects; it may also induce gastro-intestinal haemorrhage, occasionally major.

Aspirin may enhance the activity of coumarin anticoagulants and oral hypoglycaemic agents. The activity of methotrexate may be markedly enhanced and its toxicity increased. The toxicity of sulphonamides may also be increased.

Aspirin diminishes the effect of uricosuric agents such as probenecid and sulphinpyrazone. An overdose can cause hepatic necrosis.

Overdosage: Normal procedures for overdosage with aspirin, paracetamol and codeine should be followed. Gastric lavage may be helpful. Early assessment of the severity of paracetamol poisoning by measurement of plasma paracetamol levels is essential if treatment, which should be instituted within ten hours of ingestion, is to be effective. Present evidence suggests that cysteamine, methionine or N-acetylcysteine given within this period are effective in greatly reducing the toxic effects of paracetamol. Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Pharmaceutical precautions Myolgin tablets should be stored in a tightly-closed container, in a cool dry place and protected from the light.

Legal category P.

Package quantities Myolgin is available in packs of 20 and 250.

Further information Nil.

Product licence number 1866/5010.

KAODENE*

Presentation Kaodene is an aqueous suspension containing Codeine Phosphate BP 10 mg and Light Kaolin BP 3 g in each 10 ml. It is an off-white liquid with the odour and flavour of aniseed.

Uses Kaodene is indicated for the treatment of simple diarrhoea.

Dosage and administration *Adults and Children over 12 years:* 20 ml three or four times daily.

Children from 5 to 12 years: 10 ml three or four times daily.

Contra-indications, warnings, etc Codeine phosphate is a narcotic analgesic and, given in large doses, may induce tolerance and psychological and physical dependence. At the recommended dosage, however, it is unlikely that such effects would be encountered with Kaodene.

Whilst there is no adequate evidence of safety in

human pregnancy, codeine has been widely used without apparent ill-effect for many years and studies in animals have not demonstrated any hazard.

Treatment of overdosage: Gastric lavage and symptomatic treatment as for codeine phosphate.

Pharmaceutical precautions *Recommended storage conditions:* 5°–20°C.

Legal category P.

Package quantities Bottle of 250 ml.

Further information The effect of Kaodene is to reduce gut motility, soothe the inflamed mucosa of the bowel and consolidate loose, watery faeces into normal stools. The preparation has a pleasant taste and is suitable for both adults and children.

Product licence number 0096/0045.

DEXON® 'S'

Presentation Dexon 'S' sutures are Synthetic Absorbable Sutures USP made of polyglycolic acid. They are supplied in a range of sizes from 8/0 (0.4 metric) to 2 (5 metric) in sealed, direct-dispense envelopes either as non-needled pre-cut lengths or with an extensive range of needles attached. Dexon 'S' is coloured green to enhance visibility in tissue or is also available undyed, with a natural beige colour.

Uses Dexon 'S' may be used for suturing surgical and traumatic wounds and for ligating blood vessels.

Dexon 'S', polyglycolic acid, is a synthetic absorbable material which provokes minimal tissue reaction and may therefore be used where an absorbable suture is indicated.

Absorption studies in rabbits revealed minimal absorption at 7 to 15 days, significant absorption at 30 days and essentially complete absorption in 60-90 days.

Dosage and administration As indicated in the surgical procedure.

Contra-indications, warnings, etc Dexon 'S' is contra-indicated where a non-absorbable suture is needed to provide prolonged wound support. The safe use of Dexon 'S' in neural tissue and in cardiovascular surgery has not been established. When tying Dexon 'S' special care is needed in placing the first knot.

Adverse reactions Although there have been a few reports of foreign body giant cell reactions these are not considered to be specific to Dexon 'S'. As with all suture materials inflammation at the site of absorption can occur although its incidence is less than with catgut.

Pharmaceutical precautions Discard opened, unused sutures. Do not re-sterilise.

Package quantities Sealed envelopes containing sterile sutures in sizes 8/0 (0.4 metric) to 2 (5 metric) either as non-needled pre-cut lengths or swaged to Atraumatic® steel needles of varying types and sizes. This envelope is sealed within a clear peel-apart secondary envelope. The interspace is sterile. The sales unit is boxes of 1 dozen or 3 dozen sutures.

Legal category P.

Further information Nil.

Product licence numbers 0095/0023
0095/5092

HISTOACRYL®

Presentation The tissue adhesive Histoacryl is a butyl 2-cyanoacrylate monomer, which is supplied as a sterile liquid in sealed plastic vials. Histoacryl contains a blue

dye to indicate clearly the thickness of the adhesive film applied. The plastic vials are packed in cylindrical plastic tubes.

Uses Histoacryl is a tissue adhesive for wound closure when established techniques, e.g. sutures, are inconvenient or inappropriate. Histoacryl may be used to bond tissue without sutures in surgical and traumatic wounds or in combination with sutures to provide additional security and to seal off the suture tracks.

Dosage and administration Histoacryl tissue adhesive must always be applied as a very thin film as otherwise its adhesive quality will be greatly impaired. Before Histoacryl is applied the tissue must be swabbed dry as much as possible. If larger surfaces have to be joined together Histoacryl must be applied to small patches of the total area only. After accurate adaptation the tissue surfaces to be bonded must be pressed together for one minute, however, caution must be taken to adapt the tissue exactly, because polymerization time is only 10 seconds and mistakes cannot be corrected later.

Contra-indications, warnings, etc As is the case with all cyanoacrylates, Histoacryl is contra-indicated where direct contact to nerve tissue takes place, e.g. for use on brain surface or parts of the central nervous system, since cell necrosis and scar tissue formation can be a consequence.

Contact of Histoacryl with parts of the major vascular system is contra-indicated. Blood in contact with Histoacryl polymers form thrombi. Histoacryl must not come into contact with the conjunctival sac since conglutination may occur.

It must be pointed out that the polymerisation of Histoacryl produces heat. This is insignificant as long as Histoacryl is applied as a very thin film only. An injuring degree of heat on the surrounding tissue does not occur if the adhesive is applied in such a thin layer.

Pharmaceutical precautions The adhesive should be stored in the refrigerator or freezer, and must be protected from the light if removed from the packing for any length of time.

Care must be taken that no instruments, cloths, swabs or gloves come in contact with the adhesive. In that case they stick to the tissue. Instruments which have been contaminated with adhesive can be cleaned with dimethyl formamide or acetone.

Opened vials must be discarded. Histoacryl must not be resterilised.

Legal category P.

Package quantities 1 Box of Histoacryl contains 5 vials. Each vial contains 0.5 g of monomer.

Further information Nil.

Product licence number 3551/0001.

KIEL BONE GRAFT

Presentation Kiel Bone Graft, prepared by the method of Maatz and Bauermeister, is a mineral and collagenous matrix specially processed from calf bone, purified and γ -sterilised. According to the nature of the materials selected, Kiel Bone Graft consists of spongy or cortical tissue or a combination of both in various proportions. The grafts are packed in sterile double plastic bags in an outer box.

Uses The usual indications for Kiel Bone Graft are replacement of bone cysts, intervertebral locking, reparation of bone surface defects and the use as osteotomy wedges.

Dosage and administration As indicated in the surgical procedure.

Contra-indications, warnings, etc Kiel Bone Graft should not be implanted into a potentially infected host site. If the nature of the implant bed precludes the resorption process and the ingrowth of new bone, Kiel Bone Graft should not be used.

Pharmaceutical precautions Store in a dry place at room temperature. Opened and unused packages should be discarded and Kiel Bone Graft should not be resterilised.

Legal category P.

Package quantities Kiel Bone Graft is available in various sizes and types. Boxes contain 1 to 33 packages.

Further information Nil.

Product licence number 3551/5900.

LYODURA*

Presentation Lyodura is a sterile transplant material consisting of a mesh-like texture of collagenous fibres, which is developed from homologous human dura mater cerebri by special processing, lyophilised and gamma-ray sterilised. Lyodura is supplied in sterile double peel pouches in several sizes.

Uses Lyodura is a patch material which is substituted after implantation by connective tissue. Lyodura is used in the repair of defects, lesions and as a reinforcement of body tissue, e.g. for covering and sealing defects and for sheathing and securing sutures, in neuro-thoracic and general surgery.

Dosage and administration As indicated in the surgical procedure. Lyodura must be rehydrated before use.

Contra-indications, warnings, etc The use of Lyodura in an infected operating region is contra-indicated since the healing-in of Lyodura cannot be expected in such a case. The use of Lyodura as a replacement for parts of the arterial system of the heart wall must be considered as being contra-indicated.

Degenerative changes in scarred wall replacement can cause aneurisms and calcification.

Pharmaceutical precautions Store in dry place at room temperature. Opened and unused packages should be discarded and material must not be resterilised.

Legal category P.

Package quantities Lyodura is available in the following dimensions:

1. 6 × 14 cm package containing 1 piece	Cat. No.
	106 002
2. 4 × 10 cm package containing 1 piece	106 004
3. 2 × 10 cm package containing 2 pieces	106 008
4. 4 × 5 cm package containing 2 pieces	106 006
5. 1.5 × 3 cm package containing 5 pieces	106 010
6. 1.5 × 3 cm package containing 5 pcs., perforated	106 011
7. Patches 9 and 14 mm packages with 3 pcs. each	106 015

Further information Nil.

Product licence number 3551/0004.

SOFTGUT* (SOFT-CATGUT-BRAUN)

Presentation

1. *Plain*: Uniform, firmly twisted strand of collagen prepared from healthy mammals, purified, softened, dry packed and sterilised. Available in sizes 6/0 to 3 (i.e. 1 to 7 metric).
2. *Chromic*: Uniform, firmly twisted strands of collagen from healthy mammals, purified, treated with chromicising agent, softened, dry packed and sterilised. Available in sizes from 6/0 to 3 (i.e. 1 to 7 metric).

Uses Soft-Catgut-Braun is Sterile Surgical Catgut BP which may be used for suturing surgical and traumatic wounds and for ligating blood vessels. It may be used in practically all tissues. Soft-Catgut-Braun Plain is relatively rapidly absorbed and should therefore be used only where short term wound support is required. It is generally considered advisable to use Soft-Catgut-Braun Chromic where somewhat more prolonged wound support is desired.

Dosage and administration As indicated in the surgical procedure.

Contra-indications, warnings, etc Soft-Catgut-Braun is contra-indicated where a non-absorbable suture is needed to provide prolonged wound support.

Opened and unused sutures should be discarded and material must not be resterilised. Adverse reactions may include tissue reaction or inflammation.

Pharmaceutical precautions Store in a dry place at room temperature. Discard opened unused sutures.

Package quantities Sutures are available in varying sizes from 6/0 to 3 (i.e. 1 to 7 metric) in non-needed precut lengths or swaged to non-traumatic stainless steel needles of varying types and sizes. Outer boxes contain either precuts or needle thread combinations.

Legal category P.

Further information Nil.

Chromic 3551/0008

STERILISED SURGICAL CATGUT

Presentation 1. *Plain*: Uniform, firmly twisted strands of collagen prepared from healthy mammals, purified and

sterilised. Available in sizes of 5/0 to 3 (i.e. 1.5 to 7 metric).

2. *Mild Chromic*: Black, uniform, firmly twisted strands of collagen (treated with chromicising agent) from healthy mammals, purified and sterilised. Available in sizes 7/0 to 4/0 (i.e. 0.7 to 2 metric).

3. *Chromic*: Uniform, firmly twisted strands of collagen (treated with chromicising agent) from healthy mammals, purified and sterilised. Available in sizes 4/0 to 3 (i.e. 2 to 7 metric).

Uses Sterilised Surgical Catgut may be used for suturing surgical and traumatic wounds and for ligating blood vessels. It may be used in practically all tissues. Catgut is relatively rapidly absorbed and should therefore be used only where short-term wound support is required. It is generally considered advisable to use Chromic Catgut where somewhat more prolonged wound support is desired.

Dosage and administration As indicated in the surgical procedure.

Contra-indications, warnings, etc Sterilised Surgical Catgut is contra-indicated where a non-absorbable suture is needed to provide prolonged wound support.

Opened and unused sutures should be discarded and material must not be re-sterilised. Adverse reactions may include tissue reaction or inflammation. Wound dehiscence and bleeding may occasionally occur.

Pharmaceutical precautions Store in a cool dry place. Discard opened unused sutures.

Legal category P.

Package quantities Sutures are available in varying sizes (Plain 5/0 to 3; Mild Chromic 7/0 to 4/0; and Chromic 4/0 to 3) in non-needed pre-cut lengths or swaged to Atraumatic® steel needles of varying types and sizes in three dozen packages (N.B. certain ophthalmic sutures are available in one dozen packages).

Further information Nil.

DICYNENE*

Presentation *Dicynene Tablets 500 mg.* Each oval white, bi-convex tablet, engraved 'DICYNENE' one side, '500' on the other, contains 500 mg ethamsylate.

Dicynene Tablets 250 mg: Each circular, white bi-convex tablet, engraved 'DICYNENE' on one side, contains 250 mg of ethamsylate.

Dicynene 1000 Injection: Each clear glass 2 ml Snapule printed 'DICYNENE 1000' contains 1 g ethamsylate.

Dicynene Injection: Each clear glass 2 ml Snapule printed 'DICYNENE' contains 250 mg ethamsylate.

Uses Dicynene is a synthetic non-hormonal agent, which is used either orally or parenterally to reduce excessive capillary blood loss. Dicynene acts principally by maintaining capillary integrity probably by promoting polymerisation of mucopolysaccharide in vessel walls.

Following systemic administration of Dicynene, the mean bleeding time is significantly reduced without any effect on cell counts, fibrinolysis, plasma protein levels, prothrombin time and clotting time. Dicynene does not produce a vasoconstricting action nor does it have any effect on hepatic or renal function.

Dicynene is used clinically for the prophylaxis and treatment of small-vessel haemorrhage. Clinical reports show the value of Dicynene in the following indications.

Gynaecology: Non hormonal control of menorrhagia and control of bleeding during gynaecological surgery.

Paediatrics: Limiting or preventing periventricular haemorrhage in low birth weight babies.

Urology: Control of haemorrhage during and after prostatectomy. Symptomatic control of urinary tract haemorrhage of unknown aetiology.

Oral and dental surgery: Control of haemorrhage following oral surgery and dental extractions.

Ophthalmology: Control of surgical haemorrhage and retinal bleeding.

ENT: Epistaxis and control of surgical haemorrhage (e.g. tonsillectomy, adenoidectomy, middle ear surgery).

General surgery: Control of haemorrhage occurring during or after surgery.

General medicine: The prophylaxis and treatment of small vessel haemorrhage occurring in the gastro-intestinal or respiratory tract; the control of haemorrhage during anticoagulant therapy.

Dosage and administration *Adult dosage: Menorrhagia:* One 500 mg tablet four times a day from the start of bleeding until menstruation ceases.

Pre-surgical prophylaxis: 1 g from Dicynene 1000 Injection (or Dicynene Injection) either intramuscularly with the premedication or intravenously at induction of anaesthesia.

Haemorrhagic emergency: 1 g from Dicynene 1000

Injection intravenously. When used in conjunction with high molecular weight plasma volume expanders Dicynene is more effective if given prior to these agents.

Maintenance therapy: 500 mg intravenously, intramuscularly or orally every four to six hours.

Paediatric dosage: 500–750 mg parenterally for the control of haemorrhage; 250 mg orally or parenterally every four to six hours for maintenance therapy.

Neonatal dosage: 12.5 mg/kg intravenously or intramuscularly six hourly.

Contra-indications, warnings, etc There are no known contra-indications. Dicynene is well tolerated even in high dosage or during prolonged treatment. To date there has been no evidence of thrombogenic effect with Dicynene except in one series where six out of 23 Dicynene treated patients gave positive results postoperatively with the ¹²⁵I-labelled fibrogen technique, compared with 0 out of 19 in the placebo group. Only one of the Dicynene treated patients had a clinically apparent deep vein thrombosis.

Dicynene has been used without ill effect in patients with a history of thrombosis. Following intravenous injection a transient fall in blood pressure of the order of 30 mm Hg, lasting four to five minutes, has been reported. No major side-effects have been reported. Occasional headaches and skin rashes have been reported which usually disappear on reduced dosage. Nausea may occur in a small number of patients; however, this can be overcome by administering the dose after food.

Pharmaceutical precautions *Tablets:* Protect from light and moisture.

Ampoules: Protect from light. Discard if solution coloured.

Legal category POM.

Package quantities

Tablets 500 mg:	Securitainers of 100
Tablets 250 mg:	Securitainers of 100
Injection:	10 × 2 ml 'Snapules'
1000 Injection:	10 × 2 ml 'Snapules'

Further information Ethamsylate is a white crystalline powder, odourless with a slight saline taste and is readily soluble in water (62.8% at 18°C), producing a near neutral solution (pH 6.5).

Pharmacological effects appear within one to five minutes of parenteral administration and within one hour of oral administration. Dicynene is excreted unchanged via the urinary, biliary and intestinal routes and after one hour only 6.5–11.5% remains in the blood. Dicynene was found to have no teratogenic effects when studied in experimental animals over three generations.

ETOPHYLATE*

Presentation *Adult formulations: Etophylate Forte Tablets:* White, circular, bi-convex tablets engraved 'ETOPHYLATE FORTE' one side, scored on the other, each containing 500 mg acepifylline.

Etophylate Forte Syrup: Clear tangerine, citrus-flavoured syrup containing 500 mg acepifylline per 5 ml.

Etophylate Suppositories: White, wax, torpedo-shaped and preformed in white plastic in strips of six. Each suppository contains 500 mg of acepifylline.

Etophylate Ampoules: Clear glass, printed 2 ml 'snap-ules'. Each ampoule contains 500 mg acepifylline.

Paediatric formulations: Etophylate Tablets: White, circular, bi-convex tablets engraved 'ETOPHYLATE' on one side, each containing 250 mg acepifylline.

Etophylate Syrup for Children: Clear yellow, citrus-flavoured syrup containing 125 mg acepifylline per 5 ml.

Etophylate Paediatric Suppositories: White, waxy, torpedo-shaped and preformed in white plastic in strips of six. Each suppository contains 100 mg acepifylline.

Uses Etophylate is used clinically for: relief of bronchospasm in bronchitis and asthma; emergency relief of status asthmaticus; cor pulmonale; pulmonary manifestations of left ventricular failure.

Dosage and administration *Adult dosage: Etophylate Forte Tablets:* 1-2 tablets three times daily.

Etophylate Forte Syrup: 5-10 ml three times daily.

Etophylate Suppositories: 1-3 suppositories in 24 hours, 2 may be inserted at bedtime in severe cases of nocturnal dyspnoea.

Etophylate Ampoules: Intravenous: 1-2 ampoules as required.

Intramuscular: 1-4 ampoules daily.

Paediatric dosage: Etophylate Syrup for Children: Under 1 year: 2.5 ml three or four times daily.

1-5 years: 5 ml three or four times daily.

5-12 years: 10 ml three or four times daily.

Etophylate Tablets: 5-12 years: 1 tablet three or four times daily.

Etophylate Paediatric Suppositories: Under 1 year: 1 daily.

1-5 years: 2 daily.

5-12 years: 3 daily.

Contra-indications, warnings, etc

Contra-indications: None known.

No major side-effects have been reported. Gastric irritation has not been reported following the use of the oral formulations; proctitis has been reported on one occasion only following the use of the suppositories.

Intramuscular injections are pain-free, however, the intravenous injection should be given slowly over a period of approximately one minute to reduce the risk of headaches and giddiness arising from a possible fall in blood pressure.

Etophylate Forte Syrup is not recommended for use in children under 12 years of age.

Treatment of overdosage should be as for theophylline. If overdosage occurs with symptoms of nausea, vomiting, fall in blood pressure, tachycardia or collapse, treatment should be supportive and include the use of i.v. pressor drugs.

Pharmaceutical precautions The only special precautions are:

1. Suppositories must be stored in a cool place.
2. Etophylate Forte Syrup should be shaken before use as a slight sediment may appear on storage especially in cold conditions. The sediment readily re-dissolves on shaking.
3. If dilution of either syrup is considered necessary, it may be diluted with Syrup BP or Syrup BP preserved with para-hydroxy-benzoic acid esters only.

Legal category Tablets P.

KIDITARD*

Presentation Hard gelatin capsules, size 0, with clear light blue and clear dark blue shell. Each capsule contains 250 mg quinidine bisulphate (equivalent to 200 mg quinidine sulphate) in the form of sustained release micro-pellets.

Uses Sustained release quinidine therapy. The active ingredient is absorbed from the gastro-intestinal tract over a 12 hour period. An even pattern of release of the drug is established which prevents excessively high initial blood levels and therefore limits undesirable side effects. The sustained release capsules permit a twice daily dosage regime and prevent wide fluctuation in plasma quinidine levels.

Kiditard capsules are used clinically for: Extra-systoles; Paroxysmal atrial tachycardia; Nodal tachycardia; Atrial fibrillation; Atrial flutter; Paroxysmal ventricular tachycardia; Maintenance of sinus rhythm following restoration by electro-conversion.

Dosage and administration Kiditard dosage should be individually adapted to each patient. As a rule, treatment should commence with two sustained release capsules every 10-12 hours, after a test dose of 1 capsule to test for patient sensitivity.

Kiditard capsules are not recommended for use in children.

Contra-indications, warnings, etc Acute infections, atrio-ventricular block and idiosyncrasy to quinidine form absolute contra-indications to Kiditard therapy. Special care must be taken with heavily digitalised patients and in patients with congestive heart failure, hypotension or ventricular tachycardia due to possible overdosage with quinidine. Special care is also needed in patients on prolonged anti-coagulant treatment since cases of quinidine-induced hypoprothrombinaemic haemorrhage have been recorded. Patients should be carefully observed for their reactions to the first dose of the drug since idiosyncrasy is a possible response to quinidine. The following allergic reactions to quinidine have been reported: urticaria, purpura, asthma, thrombocytopenia. Gastro-intestinal upset, commonly associated with quinidine therapy, is largely avoided through the use of Kiditard. There are reports of hepatitis due to quinidine; none has been fatal and signs and symptoms disappear on withdrawal. Cardiotoxic side-effects (ventricular extra systole, A-V block, increased QRS complex above 50%, ventricular tachycardia) may occur; repeated high doses may lead to cinchonism.

If overdosage occurs treatment should be as for quinidine. Gastric lavage and a saline purgative should be employed. Promote excretion by acidifying urine with ammonium chloride. Maintain fluid balance and blood pressure. Assist respiration and monitor cardiac rhythm.

Pharmaceutical precautions Protect from light and moisture.

Legal category POM.

Package quantities Aluminium cans containing 100 capsules.

Further information Nil.

Product licence number 0357/0012.

PRIADEL

Presentation Controlled release lithium carbonate tablets: white, circular, bi-convex tablets engraved PRIADEL one side, scored on the other side. Each tablet contains 400 mg Lithium Carbonate Ph Eur in a controlled release dosage form.

Uses Controlled release lithium therapy for:

1. Treatment of mania and hypomania.
2. Treatment of depression in patients who
 - (a) are suffering from recurrent bipolar affective disorder and in whom it is intended that long term lithium prophylaxis will be used or
 - (b) are suffering from recurrent depressive illness with some bipolar, endogenous or obsessional features, or a family history of bipolar illness, indicating a probable response to lithium therapy or
 - (c) have failed to respond to other antidepressive treatments.
3. Prophylactic treatment of recurrent affective disorders.

Dosage and administration A simple treatment schedule has been evolved which except for some minor variations should be followed whether using Priadel therapeutically or prophylactically. The minor variations to this schedule depend on the elements of the illness being treated and these are described later.

1. In patients of average weight (70 kg) an initial dose of 1-3 tablets (400-1,200 mg) of Priadel may be given as a single daily dose in the morning or on retiring. Alternatively, the dose may be divided and given morning and evening. When changing from other lithium preparations serum lithium levels should first be checked, then Priadel therapy commenced at a daily dose as close as possible to the dose of the other form of lithium. As bioavailability varies from product to product (particularly with regard to retard or slow release preparations) a change of product should be regarded as initiation of new treatment.

2. Four to five days after starting treatment (and never longer than one week) a blood sample should be taken for the estimation of serum lithium level.

3. The objective is to adjust the Priadel dose so as to maintain the serum lithium level permanently within the diurnal range of 0.5-1.5 mmol/l. In practice, the blood sample should be taken between 12 and 24 hours after the previous dose of Priadel. 'Target' serum lithium concentrations at 12 and 24 hours are shown in the table below.

	<i>'Target' serum lithium concentration (mmol/l)</i>	
	<i>At 12 hours</i>	<i>At 24 hours</i>
Once daily dosage	0.7-1.0	0.5-0.8
Twice daily dosage	0.5-0.8	

Serum lithium levels should be monitored weekly until stabilisation is achieved.

4. Lithium therapy should not be initiated unless adequate facilities for routine monitoring of serum concentrations are available. Following stabilisation of serum lithium levels, the period between subsequent estimations can be increased gradually but should not normally exceed three months. Additional measurements should be made following alteration of dosage, on development of intercurrent disease, during manic or depressive relapse, following significant change in sodium or fluid intake, or if signs of lithium toxicity occur.

5. Whilst a high proportion of acutely ill patients may respond within three to seven days of the commencement of Priadel therapy, Priadel should be continued through any recurrence of the affective disturbance. This is important as the full prophylactic effect may not occur for up to 12 months after the initiation of therapy.

6. In patients who show a positive response to Priadel therapy, treatment is likely to be long term. Careful clinical appraisal of the patient should be exercised throughout medication (see Precautions).

Prophylaxis against recurrent mania and hypomania, manic depressive illness, recurrent depression: It is recommended that the described treatment schedule is followed.

Treatment of acute mania, hypomania and depression: It is likely that a higher than normal Priadel intake may be necessary during an acute phase. Therefore as soon as control of mania or depression is achieved, the serum lithium level should be determined and it may be necessary, dependent on the results, to lower the dose of Priadel and re-stabilise serum lithium levels. In all other details the described treatment schedule is recommended.

Use in elderly: In elderly patients or those below 50 kg in weight, it is recommended that the starting dose be 1

tablet (400 mg). Elderly patients may be more susceptible to side effects even at lower serum levels and also may require lower doses in order to maintain normal serum lithium levels. It follows therefore that long term treatment patients often require a reduction in dosage over a period of years.

Safety in pregnancy: There is epidemiological evidence that lithium may be harmful to the foetus in human pregnancy.

<i>Total no. 'lithium babies' reported</i>	<i>Malformed infants</i>	<i>Ebstein's anomaly and other major cardiovascular malformations</i>
225	25 (11%)	18 (8%)

It is strongly recommended that lithium be discontinued before a planned pregnancy. If it is considered essential to maintain Priadel treatment during pregnancy, serum lithium levels should be closely monitored since renal function changes gradually during pregnancy and suddenly at parturition requiring dosage adjustments. It is recommended that lithium be discontinued shortly before delivery and recommenced a few days post-partum.

Babies may show signs of lithium toxicity necessitating fluid therapy in the neonatal period. Babies born with low serum lithium concentrations may have a flaccid appearance which returns to normal without any treatment. Lithium is secreted in breast milk, therefore bottle feeding is recommended.

Contra-indications, warnings, etc

Contra-indications. Renal insufficiency, cardiovascular insufficiency, Addison's disease and untreated thyroid dysfunction are all contraindications to lithium therapy.

Precautions: When considering Priadel therapy, it is necessary to ascertain whether patients are receiving lithium in any other form. If so, check serum levels before proceeding. It is important to ensure that renal function is normal – if necessary a creatinine clearance test or other renal function test should be performed. Cardiac and thyroid function should be assessed before commencing lithium treatment. Patients should be euthyroid before the initiation of lithium therapy. Renal function, cardiac function and thyroid function should be reassessed periodically.

Clear instructions regarding the symptoms of impending toxicity should be given by the doctor to all patients receiving long term lithium therapy (see Warnings and Adverse Effects). Patients should also be warned to report if polyuria or polydipsia develop. Episodes of nausea and vomiting or other conditions leading to salt/water depletion (including severe dieting) should also be reported.

Caution should be exercised to ensure that diet and fluid intake are normal thus maintaining a stable electrolyte balance. This may be of special importance in very hot weather or work environment. Infectious diseases including colds, influenza, gastro-enteritis and urinary infections may alter fluid balance and thus affect serum lithium levels. Treatment should be discontinued during any intercurrent infection and should only be re-instituted after the patient's physical health has returned to normal.

In patients undergoing surgery, lithium intoxication may result from pre-operative fluid deprivation. Lithium

should preferably be discontinued 24–48 hours before operation and recommenced only when the post-operative recovery period is safely over and normal fluid balance restored. Where interruption of lithium therapy is impractical, e.g. during a course of E.C.T., serum lithium concentration should be carefully monitored pre-operatively and fluid balance maintained. There are also reports of interaction between lithium and neuromuscular blocking agents which may result in delayed recovery from anaesthesia.

Drug interactions: Concurrent use of lithium and diuretics may cause reduced lithium clearance, leading to intoxication. If a diuretic has to be prescribed for a lithium patient, the lithium dosage should first be lowered and the patient re-stabilised with frequent monitoring. Similar precautions should be exercised on diuretic withdrawal. Other drugs affecting electrolyte balance (e.g. appetite suppressants, steroids) may alter lithium excretion and should be avoided in patients on lithium. Raised plasma levels of ADH may occur during treatment. If other psychotropic drugs are used they should be initiated at a lower dosage than usual, as their side effects may be potentiated by the use of lithium. This has been shown to be of particular importance for the concurrent use of lithium and haloperidol or flupenthixol.

There have been isolated reports of possible interactions between lithium and diazepam (resulting in hypothermia), methylgopa, propranolol, tetracyclines, phenytoin and indomethacin.

Warnings and adverse effects: *Side effects:* Side effects are usually related to serum lithium concentrations and are infrequent at levels below 1.0 mmol/l.

Mild gastrointestinal effects, nausea, vertigo, muscle weakness and a dazed feeling may occur initially, but frequently disappear after stabilisation. Fine hand tremors, polyuria and mild thirst may persist. Weight gain or oedema may present in some patients but should not be treated with diuretics.

Hypercalcaemia, hypermagnesaemia and hyperparathyroidism have been reported. Skin conditions including acne, psoriasis, generalised pustular psoriasis, rashes and leg ulcers have occasionally been reported as being aggravated by lithium treatment.

Long term treatment with lithium may be associated with disturbances of thyroid function, including goitre, hypothyroidism and thyrotoxicosis. Lithium-induced hypothyroidism may be managed successfully with concurrent thyroxine.

Nephrotoxicity: Up to one third of patients on lithium may develop polyuria with a urinary output of up to three litres per day. This is usually due to lithium blocking the effect of ADH and is reversible on lithium withdrawal. However, long term treatment with lithium may also result in permanent changes in kidney histology and impairment of renal function. High serum concentrations of lithium including episodes of acute lithium toxicity may aggravate these changes. The minimum clinically effective dose of lithium should always be used. In patients who develop polyuria or polydipsia, renal function should be monitored, e.g. with measurement of blood urea, serum creatinine and urinary protein levels in addition to routine serum lithium estimations.

Toxic effects: Such effects are indicative of impending lithium intoxication and they fall into two groups:

1. Gastro-intestinal: increasing anorexia, diarrhoea and vomiting.
2. Central nervous system: muscle weakness, lack of

co-ordination, drowsiness or lethargy progressing to giddiness with ataxia, tinnitus, blurred vision, dysarthria, coarse tremor and muscle twitching.

At blood levels about 2–3 mmol/l there may be a large output of dilute urine, with increasing disorientation, seizures, coma and death.

Patients should be instructed to stop taking their tablets and to report immediately for a serum lithium estimation if toxic symptoms occur.

Lithium intoxication: There is no specific antidote to lithium poisoning. In the event of accumulation, lithium should be stopped and serum estimations should be carried out every six hours.

Under no circumstances should a diuretic be used. Osmotic diuresis should be promoted (mannitol or urea infusion) or alkalinisation of the urine (sodium lactate or sodium bicarbonate infusion).

If the serum lithium level is over 4.0 mmol/l, if there is a deterioration in the patient's condition, or if the serum lithium concentration is not falling at a rate corresponding to a half-life of under 30 hours, peritoneal or haemodialysis should be instituted promptly. This should be

continued until there is no lithium in the serum or dialysis fluid. Serum lithium levels should be monitored for at least a further week to take account of any possible rebound in serum lithium levels as a result of delayed diffusion from body tissues.

Pharmaceutical precautions Store in a cool, dry place. Tablets should not be crushed, chewed, or taken with hot liquids nor any attempt made to dissolve them before administration: they may be halved to provide dosage increments of 200 mg.

Legal category POM.

Package quantities Securitainers of 100 and 1,000 tablets.

Further information Nil.

Product licence number 0357/5000.

ANHYDROL FORTE* ▼

Presentation Colourless evaporative solution containing Aluminium chloride hexahydrate 20% w/v.

Uses For the topical treatment of hyperhidrosis specifically involving axillae, hands or feet.

Directions Apply to the affected sites at night, as required, and allow to dry. Wash off in the morning.

Contra-indications, warnings, etc Care should be taken to restrict the application to the affected sites only. Keep away from the eyes. Do not bathe immediately before use and, if the axillae are treated, do not shave or use depilatories on this area within 12 hours before or after use.

Pharmaceutical precautions Store in a cool place away from flames. Always replace the cap tightly after use.

Legal category POM.

Package quantity Anhydrol Forte is packed in a 10 ml glass roll-on bottle.

Further information The formulation of Anhydrol Forte has been tested in widespread clinical practice, and has been shown to be effective when used in accordance with the recommended instructions. Should irritation occur, reduce the frequency of application and if necessary apply mild hydrocortisone cream.

DITHROCREAM* ▼

Presentation *Dithrocream 0.1%*: Pale yellow oil-in-water vanishing cream containing Dithranol BP 0.1% w/w. *Dithrocream 0.25%*: Pale yellow oil-in-water vanishing cream containing Dithranol BP 0.25% w/w. *Dithrocream Forte*: Pale yellow oil-in-water vanishing cream containing Dithranol BP 0.5% w/w.

Uses For the topical treatment of sub-acute and chronic psoriasis including psoriasis of the scalp.

Directions Dithrocream should be applied sparingly to the psoriatic lesions, preferably at night, and rubbed gently and carefully into the skin until absorbed. It is most important to avoid applying an excessive quantity which may cause unnecessary soiling and staining of the clothing and/or bed linen. In the morning a bath should be taken to remove any surplus cream, which will have become red/brown in colour. The margins of the lesion will gradually become stained purple/brown as treatment progresses, but this will disappear after cessation of treatment.

For use on the scalp, shampoo to remove scalar debris and any previous application. Dry the hair and, after suitably parting, rub the cream well into the lesions.

Treatment should be continued until the skin is entirely clear; i.e. when there is nothing to feel with the fingers and the texture is normal.

Contra-indications, warnings, etc A small proportion of patients are sensitive to any form of dithranol treatment. If the initial treatment produces excessive soreness or if the lesions spread (particularly when potent topical steroids have recently been used), reduce frequency of applications and in extreme cases stop treatment.

Dithrocream Forte should only be used under close and constant medical supervision by patients who have failed to respond to lower strengths of dithranol.

Not to be used for acute psoriasis.

Keep away from the eyes and always wash hands after use.

Pharmaceutical precautions Do not expose to excessive heat.

Legal category P.

Package quantities Dithrocream is supplied in collapsible tubes containing 50 grams.

Further information Dithrocream has been developed as a vanishing cream formulation of dithranol for particular convenience for home treatment and is especially suitable for the exposed surfaces and hairy regions of the body including psoriasis of the scalp.

EMULSIDERM* ▼

Presentation Pale blue/green liquid emulsion containing Benzalkonium chloride BP 0.5%, Liquid paraffin BP 25.0%, Isopropyl myristate BPC 25.0%.

Uses An aid in the treatment of dry skin conditions, especially those associated with eczema, ichthyosis or xeroderma. It permits re-hydration of the keratin by replacing lost lipids, and its antiseptic properties assist in overcoming secondary infection.

Directions Always shake bottle before use.

For use in the bath: Add 2–3 capfuls to a 6–8 inch bath of warm water. For infant bathing use 1–2 capfuls. Soak for 5–10 minutes. Pat dry.

For application to the skin: Rub a small amount of

undiluted emollient into the dry areas of skin until absorbed.

Contra-indications, warnings, etc Keep away from the eyes. Take care to avoid slipping in the bath.

Pharmaceutical precautions Store in a cool place. Always replace cap after use.

Legal category P.

Package quantity Emulsiderm is presented in a 250 ml polythene bottle with a 10 ml measuring cap.

Further information Emulsiderm contains the antiseptic Benzalkonium chloride in an emulsion system which permits rapid dispersion of its oil content in the bath water.

Product licence number 0173/0036.

EXTEROL* ▼

Presentation Viscous solution containing Urea hydrogen peroxide 5.0% w/w.

Uses An aid in the removal of hardened ear wax.

Directions Remove the protective cap, invert the pipette above the opening of the affected ear and, with the head tilted sideways, gently squeeze 5–10 drops into the ear. Retain drops in ear for several minutes by keeping head tilted or, alternatively, by gently inserting a small plug of cotton wool into the outer ear.

Repeat once or twice daily for at least 3–4 days or as directed by the physician.

Contra-indications, warnings, etc Keep away from the eyes. Do not use if eardrum is known or suspected to be perforated. Stop usage if irritation or pain occurs.

Pharmaceutical precautions Store in a cool place. After use, always replace cap and return bottle to carton.

Legal category P.

Package quantity Exterol is presented in a 12 ml amber glass bottle, incorporating a specially designed pipette enclosed in a protective cap.

Further information After insertion of the drops into the ear, the urea hydrogen peroxide liberates oxygen which acts to break up the hardened wax. Subsequently, the glycerin and urea assist in the softening of the wax in order that it may more easily be removed from the ear, either with or without syringing. Due to the release of oxygen, patients may experience a mild, temporary effervescence in the ear.

Product licence number 0173/0037.

GLUTAROL*

Presentation Colourless evaporative solution containing Glutaraldehyde 10.0% w/v.

Uses For topical use in the treatment of viral warts with the exception of warts on the face and those in the anal and perineal regions.

Directions To be applied to the wart twice daily or as directed by the physician. Pare down hard skin if it develops on and around the wart.

Contra-indications, warnings, etc Keep away from the eyes.

Pharmaceutical precautions Glutarol should be stored in a cool place away from flames.

Legal category P.

Package quantity Glutarol is packed in a 10 ml amber glass bottle fitted with a spatula for ease of application.

Further information Glutaraldehyde is virucidal^{1, 2} and thus inactivates the wart virus. On the skin, it also acts as an anhydrotic^{3, 4} drying the warts and surrounding skin, so reducing spread of lesions and making more simple the removal of persistent warts by curettage.

As the preparation stains the outer layers of the skin brown, treatment can be seen to be carried out.⁵

SALACTOL*

Presentation A collodion paint containing Lactic acid BP 16.7% w/w, Salicylic acid BP 16.7% w/w, Flexible collodion BP 66.6% w/w.

Uses Keratolytic and antiviral. For the treatment of warts, particularly plantar warts.

Directions for use *First day:* Paint the wart and leave to dry, taking care to prevent the paint running. Cover with a waterproof plaster and leave for 24 hours.

Subsequent days: Remove the plaster and using a pumice stone rub away the treated surface of the wart. Repeat the application covering with a fresh waterproof plaster.

Contra-indications, warnings, etc Salactol should not be used on warts near the eyes. It does not normally cause any inflammation of the skin around the wart, but should this occur, treatment should be suspended until the inflammation disappears.

Pharmaceutical precautions Salactol should be stored in a cool place away from flames.

Legal category P.

Package quantity Salactol is packed in a 10 ml amber glass bottle fitted with a spatula for ease of application.

Further information In 76 patients with plantar warts 84% were cured at 12 weeks without any side-effects.¹ Salactol may be applied successfully by the patient in his own home.²

ALLEGRON®

Presentation Tablets each containing the equivalent of 25 mg nortriptyline (as the hydrochloride). The tablets are orange, scored and have a diameter of 8 mm. They are marked 'DD NN'.

Tablets each containing the equivalent of 10 mg nortriptyline (as the hydrochloride). The tablets are yellow, unscored and have a diameter of 5.5 mm. They are marked 'DN'.

Uses Allegron is indicated for the relief of symptoms of depression. It may also be used for the treatment of some cases of nocturnal enuresis.

Dosage and administration For oral administration.

Adults: The usual adult dose is 20–40 mg daily in divided doses, increasing to 100 mg daily where necessary. The usual maintenance dose is 30–75 mg/day.

The elderly: Initial dosage should be 10 mg three times a day. This may be increased with caution under close supervision. Half the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

Children: (for nocturnal enuresis only)

Age (years)	Weight		Dose (mg)
	kg	lbs	
6–7	20–25	44–55	10
8–11	25–35	55–77	10–20
> 11	35–54	77–119	25–35

The dose should be administered thirty minutes before bedtime.

The maximum period of treatment should not exceed three months. A further course of treatment should not be started until a full physical examination, including an ECG, has been made.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to nortriptyline.

Recent myocardial infarction, any degree of heart block or other cardiac arrhythmias.

Severe liver disease. Mania.

Nortriptyline is contra-indicated for the nursing mother and for children under the age of six years.

Warnings: As improvement may not occur during the initial weeks of therapy, patients, especially those posing a high suicidal risk, should be closely monitored during this period.

Withdrawal symptoms, including insomnia, irritability and excessive perspiration may occur on abrupt cessation of therapy.

The use of nortriptyline in schizophrenic patients may result in an exacerbation of the psychosis or may activate latent schizophrenic symptoms. If administered to over-active or agitated patients, increased anxiety and agita-

tion may occur. In manic-depressive patients, nortriptyline may cause symptoms of the manic phase to emerge.

Cross sensitivity between nortriptyline and other tricyclic antidepressants is a possibility.

Patients with cardiovascular disease should be given nortriptyline only under close supervision because of the tendency of the drug to produce sinus tachycardia and to prolong the conduction time. Myocardial infarction, arrhythmia and strokes have occurred. Great care is required if nortriptyline is administered to hyper-thyroid patients or to those receiving thyroid medication, since cardiac arrhythmias may develop.

Nortriptyline may impair the mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a car; therefore the patient should be warned accordingly.

Drug interactions: Under no circumstances should nortriptyline be given concurrently with, or within two weeks of cessation of, therapy with monoamine oxidase inhibitors. Hyperpyretic crises, severe convulsions and fatalities have occurred when similar tricyclic antidepressants were used in such combinations.

Nortriptyline should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Nortriptyline may decrease the anti-hypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine. Concurrent administration of reserpine has been shown to produce a 'stimulating' effect in some depressed patients. It would be advisable to review all anti-hypertensive therapy during treatment with tricyclic antidepressants.

Barbiturates may increase the rate of metabolism of nortriptyline.

Usage in pregnancy: The safety of nortriptyline for use during pregnancy has not been established, nor is there evidence from animal studies that it is free from hazard; therefore the drug should not be administered to pregnant patients or women of childbearing age unless the potential benefits clearly outweigh any potential risk.

Precautions: The elderly are particularly liable to experience adverse reactions, especially agitation, confusion and postural hypotension.

Behavioural changes may occur in children receiving therapy for the treatment of nocturnal enuresis.

If possible, the use of nortriptyline should be avoided in patients with narrow angle glaucoma, symptoms suggestive of prostatic hypertrophy or a history of epilepsy.

When it is essential, nortriptyline may be administered with electroconvulsive therapy, although the hazards may be increased.

Anaesthetics given during tricyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the drug should be

discontinued, if possible, for several days prior to the procedure, or the anaesthetist should be informed if the patient is still receiving therapy.

Tricyclic antidepressants may potentiate the CNS depressant effect of alcohol.

Both elevation and lowering of blood sugar levels have been reported.

Side-effects: Cardiac arrhythmias and severe hypotension are likely to occur with high dosage, or in patients with pre-existing heart disease taking normal dosage.

Other common side-effects include drowsiness, sweating, postural hypotension, tremor and skin rashes.

The following are seen occasionally: dizziness, confusion, restlessness, weakness, impotence and blurred vision. Side-effects rarely noted are epigastric distress, nausea and vomiting, dysgeusia, excessive weight gain, excessive weight loss, fatigue, insomnia, headache, paraesthesiae and pruritus.

The following adverse effects, although not necessarily all reported with nortriptyline, have occurred with other tricyclic antidepressants: atropine-like side-effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition are common early in treatment, but usually lessen.

Serious adverse effects are rare; the following have been reported: depression of the bone marrow including agranulocytosis, cholestatic jaundice, hypomania, convulsions and peripheral neuropathy.

Adverse effects such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken tricyclic antidepressants during the last trimester of pregnancy.

Overdose: Toxic overdose may result in confusion, restlessness, agitation, vomiting, hyperpyrexia, muscle rigidity, hyperactive reflexes, tachycardia, cardiac arrhythmias, ECG evidence of impaired conduction, shock, congestive heart failure, severe hypotension, stupor, coma and CNS stimulation with convulsions followed by respiratory depression. Deaths have occurred following overdose with drugs of this class.

Treatment: No specific antidote is known. General supportive measures are indicated, with gastric lavage. Activated charcoal absorbs tricyclic antidepressants very effectively. Respiratory assistance is apparently the most effective measure when indicated. The use of CNS depressants may worsen the prognosis.

Intramuscular paraldehyde or diazepam provides anticonvulsant activity with less respiratory depression than the barbiturates.

The use of digitalis and/or pyridostigmine may be considered in the event of serious cardiovascular abnormalities or cardiac failure.

The value of dialysis has not been established.

Pharmaceutical precautions Store in a cool (6°–15°C), dry place.

Legal category POM.

CAPASTAT®

Presentation Capreomycin sulphate as sterile white powder for intramuscular injection, in sealed vials each containing 1,000,000 Units (approximately equivalent to 1 g capreomycin base).

Uses For the treatment of pulmonary infections caused by capreomycin-susceptible strains of *M. tuberculosis* when the primary agents (isoniazid, rifampicin, streptomycin and para-aminosalicylic acid) have been ineffective or cannot be used because of toxicity or the presence of resistant tubercle bacilli.

Dosage and administration The usual dose is 1 g daily (not to exceed 20 mg/kg/day) given intramuscularly for 60 to 120 days, followed by 1 g intramuscularly two or three times a week. Capreomycin sulphate should be dissolved in 2 ml of 0.9% Sodium Chloride Intravenous Infusion BP or Water for Injections PhEur. Two or three minutes should be allowed for complete solution. For administration of a 1 g dose, the entire contents of the vial should be given.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to the drug.

Warnings: The use of capreomycin in patients with renal insufficiency or pre-existing auditory impairment must be undertaken with great caution, and the risk of additional eighth cranial nerve impairment or renal injury should be weighed against the benefits to be derived from therapy.

Simultaneous administration of other antituberculous agents (e.g. streptomycin, viomycin) which also have ototoxic and nephrotoxic potential is not recommended.

Use with non-antituberculous drugs (polymyxin, colistin sulphate, gentamicin, tobramycin, vancomycin, kanamycin and neomycin) having ototoxic or nephrotoxic potential should also be undertaken only with great caution.

Usage in pregnancy: The safety of capreomycin for use during pregnancy has not been established.

The safety of capreomycin for use in infants and children has not been established.

Precautions: Audiometric measurements and assessment of vestibular function should be performed prior to initiation of therapy with capreomycin and at regular intervals during treatment.

Regular tests of renal function should be made throughout the period of treatment, and reduced dosage should be employed in patients with known or suspected renal impairment.

Since hypokalaemia may occur during capreomycin therapy, serum potassium levels should be determined frequently.

Capreomycin should be administered cautiously to patients with a history of drug allergy.

Side-effects: Kidney – Elevation of serum creatinine or serum urea and abnormal urine sediment have been observed.

Liver – A decrease in bromsulphthalein excretion without change in serum enzymes has been noted in the presence of pre-existing liver disease. Abnormal results in liver function tests have occurred in many patients receiving capreomycin in combination with other antituberculous agents which are also known to cause changes in hepatic function. Periodic determinations of liver function are recommended.

Blood – Leucocytosis and leucopenia have been observed.

Hypersensitivity – Urticaria and maculopapular skin rashes associated in some cases with febrile reactions have been reported when capreomycin and other antituberculous drugs were given concomitantly.

Ototoxicity – Clinical and subclinical auditory loss has been noted. Some audiometric changes are reversible, and others with permanent loss are not progressive following withdrawal of capreomycin. Tinnitus and vertigo have occurred.

Pain and induration at the injection sites have been observed. Excessive bleeding at the injection site has been reported. Sterile abscesses have been noted.

Pharmaceutical precautions *Dry powder:* Store in a cool (6°–15°C), dry place. *When reconstituted:* The solution should be stored in a refrigerator (0°–6°C) and be used within 14 days. At room temperature (15°–25°C) it should be used within 48 hours.

Legal category POM.

Package quantities Vials of 1,000,000 Units (1 g base approximately). Pack of 5 vials.

Further information Must be used only in conjunction with adequate doses of other antituberculous drugs. The use of Capastat alone allows the rapid development of strains resistant to it. Frequent cross-resistance occurs between capreomycin and viomycin. Varying degrees of cross-resistance between capreomycin and kanamycin or neomycin have been reported. No cross-resistance has been observed between capreomycin and isoniazid, aminosalicylic acid, cycloserine, streptomycin, ethionamide or ethambutol.

Product licence number 0006/5005.

DIREMA*

Presentation Tablets each containing the equivalent of 25 mg Hydrochlorothiazide BP. The tablets are white, blank and unscored, with a diameter of 7 mm.

Tablets each containing the equivalent of 50 mg Hydrochlorothiazide BP. The tablets are white, unscored, with a diameter of 8 mm and marked 'DD HF'.

Uses Oral diuretic. All oedematous states where a diuretic is required. Hypertension in conjunction with hypotensive drugs.

Dosage and administration For oral administration.

Oedema: From 25 mg once or twice daily to 75 mg or 100 mg twice daily, depending on the severity of the oedema and the response secured. Doses should be taken at breakfast time and shortly after lunch, so that the main diuretic action occurs during the day; the patient's sleep is then undisturbed.

Hypertension: Direma potentiates the action of hypotensive drugs, especially the ganglion blocking agents. Thus when it is used in conjunction with hypotensives, the dosage of the latter should be reduced immediately by 25–50%. The recommended starting dosage with Direma is 25–50 mg once or twice daily, with subsequent adjustments determined by the patient's response. By adopting combined therapy of this type the resultant control of blood pressure is usually smoother, with less fluctuation between doses.

Contra-indications, warnings, etc

Contra-indication: No contra-indications are known.

Side-effects and precautions: Direma rarely gives rise to

side-effects. If mild nausea is noticed doses should be taken with meals or with a short drink of milk or water. To avoid the risk of potassium depletion, it is sound practice to limit therapy to four-day periods with potassium chloride or potassium citrate being administered during the next three days at doses of 2–4 g daily. Alternatively, Direma may be given for a two-week period followed by a course of potassium during the third week. Whichever routine is adopted, the cycle is repeated as necessary – with suitable adjustments of dosage according to the patient's response.

When Direma is prescribed for patients already receiving digitalis, they should be monitored for signs of digitalis overdose as a secondary effect of potassium depletion. When there is impairment of renal function, Direma may cause some increase in blood urea. Should this occur, dosage should be reduced or the treatment completely withheld for a few days.

Warning: The safety of Direma for use during pregnancy has not been established.

Pharmaceutical precautions Store in a cool (6°–15°C), dry place.

Legal category POM.

Package quantities Tablets 25 mg: Bottles of 100. Tablets 50 mg: Bottles of 100.

Further information Nil.

Tablets 25 mg 0006/5006

Tablets 50 mg 0006/5007

DISTACLOR* ▼

Presentation Capsules (violet and white, printed Distaclor 250) containing 250 mg cefaclor.

Granules (pink) for suspension containing 125 mg cefaclor/5 ml.

Granules (pink) for suspension containing 250 mg cefaclor/5 ml.

Uses Distaclor is indicated for the treatment of the following infections due to susceptible micro-organisms:

Respiratory tract infections, including pneumonia, bronchitis, exacerbations of chronic bronchitis, pharyngitis and tonsillitis.

Otitis media.

Skin and soft tissue infections.

Urinary tract infections, including pyelonephritis and cystitis.

Distaclor has been found to be effective in both acute and chronic urinary tract infections.

Cefaclor is active against the following organisms *in vitro*:

Alpha- and beta-haemolytic streptococci

Staphylococci; including coagulase-positive, coagulase-negative and penicillinase-producing strains

Streptococcus pneumoniae

Escherichia coli

Proteus mirabilis

Klebsiella species

Haemophilus influenzae, including ampicillin-resistant strains.

Cefaclor has no activity against *Pseudomonas* species.

Cefaclor is not active against most strains of enterococci (*Str. faecalis*), *Enterobacter*, indole-positive *Proteus* and *Serratia* species. Some rare strains of staphylococci are resistant to cefaclor.

Dosage and administration Distaclor is administered orally.

Adults: The usual adult dosage is 250 mg every eight hours. For more severe infections or those caused by less susceptible organisms, doses may be doubled. Doses of 4 g per day have been administered safely to normal subjects for 28 days, but the total daily dosage should not exceed this amount.

Distaclor may be administered in the presence of impaired renal function. Under such conditions dosage is unchanged (see *Precautions*).

Patients undergoing haemodialysis: Haemodialysis shortens serum half-life by 25–30%. In patients undergoing regular haemodialysis, a loading dose of 250 mg–1 g administered prior to dialysis and a therapeutic dose of 250–500 mg every six to eight hours maintained during interdialytic periods is recommended.

Children: The usual recommended daily dosage for children is 20 mg/kg/day in divided doses every eight hours, as indicated.

Distaclor suspension

	125 mg/5 ml	250 mg/5 ml
< 1 year	2.5 ml tid	
1–5 years	5.0 ml tid	
Over 5 years		5.0 ml tid

In more serious infections, otitis media and infections caused by less susceptible organisms, 40 mg/kg/day is recommended, up to a daily maximum of 1 g.

In the treatment of beta-haemolytic streptococcal infections, therapy should be continued for at least 10 days.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to cephalosporins.

Warnings: Cephalosporins should be given cautiously to patients with known penicillin sensitivity, as there is evidence of partial cross-allergenicity between the penicillins and cephalosporins. Severe reactions (including anaphylaxis) have been reported occasionally in patients receiving penicillins or cephalosporins.

Usage in pregnancy: The safety of cefaclor for use during pregnancy has not been established.

Precautions: If an allergic reaction to cefaclor occurs the drug should be discontinued and the patient treated with the appropriate agents.

Cefaclor should be administered with caution in the presence of markedly impaired renal function. Under such conditions, safe dosage may be lower than that usually recommended.

Prolonged use of cefaclor may result in the overgrowth of non-susceptible organisms. If superinfection occurs during therapy, appropriate measures should be taken.

Positive direct Coombs' tests have been reported during treatment with the cephalosporin antibiotics. In haematological studies or in transfusion cross-matching procedures when anti-globulin tests are performed on the minor side, or in Coombs' testing of newborns whose mothers have received cephalosporin antibiotics before parturition, it should be recognised that a positive Coombs' test may be due to the drug.

A false-positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with copper sulphate test tablets, but not with Tes-Tape* (urine sugar analysis paper, Lilly).

Side-effects: Gastro-intestinal – The most frequent side-effect has been diarrhoea. It is rarely severe enough to warrant cessation of therapy. Colitis, including rare instances of pseudomembranous colitis, has been reported. Nausea and vomiting have also occurred.

Hypersensitivity – Allergic reactions, such as urticaria, morbilliform eruptions and pruritus, have been observed. These reactions usually subsided upon discontinuation of therapy. Serum sickness-like reactions, including the above skin manifestations, fever and arthralgia/arthritis, have been reported. Anaphylaxis has also occurred.

Liver – Slight elevations in AST (SGOT) and ALT (SGPT) have been reported.

Miscellaneous – Eosinophilia, positive Coombs' tests and genital pruritus and vaginitis have occurred.

Pharmaceutical precautions Store at room temperature (15–25°C). Keep containers tightly closed and protect from light. After reconstitution, the suspension should be stored in a refrigerator (0–6°C) and be used within 14 days. When dilution is unavoidable, Syrup BP should be used after the suspension has been prepared according to the manufacturer's instructions.

DISTALGESIC*

DISTALGESIC* Soluble

Presentation Tablets each containing 32.5 mg Dextropropoxyphene Hydrochloride BP (equivalent to approximately 30 mg dextropropoxyphene base) with 325 mg Paracetamol PhEur. The tablets are white, pillow-shaped, film coated, 14 mm in length and marked 'DG'.

Soluble tablets each containing 50 mg Dextropropoxyphene Napsylate BP (equivalent to 32.5 mg dextropropoxyphene hydrochloride or 30 mg dextropropoxyphene base) with 325 mg Paracetamol PhEur. The tablets are white, octagonal, with a diameter of 12.5 mm and marked 'DGS'.

Uses Analgesic: For the management of mild to moderate pain.

Dosage and administration For oral administration to adults only.

Dosage: The usual dose is 2 tablets three or four times daily and should not normally be exceeded.

Soluble tablets should be stirred in a little water until dispersed.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to dextropropoxyphene or paracetamol.

Warnings: Dextropropoxyphene is an analgesic with CNS depressant properties and should be used with caution in patients who are receiving other CNS

depressant drugs, as an additive effect may occur. Patients should be warned to avoid alcohol.

As with other drugs which affect the CNS, care should be taken when prescribing for patients with personality or other psychological disorders. Tolerance, psychological and physical dependence may rarely occur.

Like other centrally acting drugs, dextropropoxyphene may impair patients' mental and physical reactions in the performance of potentially hazardous tasks (e.g. driving ability, operation of machinery, etc.) to a varying extent, depending on dosage and individual susceptibility.

Overdosage of paracetamol may damage the liver, due to the accumulation of intermediate metabolites which cause hepatic necrosis.

Use in pregnancy: The safety of Distalgesic for use during pregnancy has not been established.

Side-effects: Side-effects such as dizziness, sedation, nausea and vomiting seem to be more prominent in ambulatory than in non-ambulatory patients, and some of these side-effects may be alleviated if the patient lies down.

Other reported side-effects include constipation, abdominal pain, skin rashes, lightheadedness, headache, weakness, euphoria, dysphoria and minor visual disturbances.

Overdosage: The chronic ingestion of dextropropoxyphene in doses exceeding 720 mg (as base) per day has caused toxic psychoses and convulsions.

Symptoms of acute toxicity may be rapid in onset, with the danger of respiratory arrest. Other recognised manifestations include respiratory depression, coma, circulatory collapse, pulmonary oedema, convulsions and cardiac arrhythmias.

Deterioration may be rapid, with fatal outcome.

Paracetamol overdosage is associated with nausea and vomiting and frequently with abdominal pain. Subsequent evidence of liver dysfunction may be apparent after 24 hours, and if severe, may lead to reversible hepatic necrosis and death.

Treatment: Primary attention should be given to the re-establishment of adequate respiratory exchange through provision of a patent airway and institution of assisted or controlled ventilation. The narcotic antagonist naloxone is a specific antidote against the respiratory depression produced by dextropropoxyphene. An appropriate dose of this antagonist should be administered, preferably by the intravenous route, simultaneously with efforts at respiratory resuscitation. Repeated doses of the antagonist may be necessary over a prolonged period due to the slow elimination of dextropropoxyphene.

In addition to the use of a narcotic antagonist, the patient may require careful titration with an anticonvulsant to control seizures. Analeptic drugs (for example, caffeine or amphetamine) should not be used because of their tendency to precipitate convulsions.

Early assessment of the severity of paracetamol poisoning by measurement of plasma paracetamol levels is essential if treatment, which should be instituted within 10 hours of ingestion, is to be effective. Present evidence suggests that cysteamine, methionine or N-acetylcysteine given within this period are effective in greatly reducing the toxic effects of paracetamol.

Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Gastric lavage may be helpful. Activated charcoal can absorb a significant amount of ingested dextropropoxyphene.

Pharmaceutical precautions Store in a cool (6°–15°C), dry place.

Distalgesic Soluble tablets: Dispense in moisture-proof containers.

Legal category POM.

Package quantities

Distalgesic tablets: Blister packs of 100 (10 strips of 10 tablets). Bottles of 100 and 500 (available to hospitals only).

Distalgesic Soluble tablets: Bottles of 50.

Distalgesic Soluble tablets 0006/5001

DISTAMINE*

Presentation Tablets each containing 50 mg, 125 mg or 250 mg D-penicillamine base.

The 50 mg tablets are white, coated, scored and have a diameter of 5.5 mm.

The 125 mg tablets are white, coated, marked 'DS', and have a diameter of 8 mm.

The 250 mg tablets are white, coated, marked 'DM', and have a diameter of 10 mm.

Uses

1. Severe, active rheumatoid arthritis unresponsive to other treatment, including juvenile forms.

2. As a chelating agent in the treatment of Wilson's disease and lead poisoning.

3. In the treatment of cystinuria in cases where high fluid regimens are not adequate.

Dosage and administration For oral administration.

1. **Rheumatoid arthritis: Adults:** Not more than 250 mg daily for the first four weeks, increasing by the amount of the starting dose at intervals of four to eight weeks until remission of symptoms commences. Many patients respond to a daily dose within the 500–750 mg range. Some need less, and others as much as 2 g daily. The therapeutic response to Distamine is delayed for several weeks so that if unnecessarily high doses are to be avoided each increment must be allowed time for its effect to develop. Rapid increase of dose or the use of full doses from the beginning gives rise to many adverse reactions without any countervailing benefits.

If suppression of rheumatoid activity appears to have been achieved at a particular dose of Distamine this dose should be maintained for at least six months and then progressively reduced by 250 mg at intervals of two to three months. Relapse after withdrawal or at an inadequate dose level usually occurs within three months. Most patients respond to further courses of Distamine.

Paediatric Dosage

Week of therapy	Weight of child	
	Less than 20 kg	More than 20 kg
0 to 2	25 mg bd	50 mg bd
2 to 4	50 mg bd	100 mg bd
4 to 6	100 mg bd	100 mg tid
6 to 10	100 mg tid	150 mg tid
10 to 14	150 mg tid	200 mg tid

As with adult patients, the dose should be kept to the lowest effective level.

2. *Wilson's disease*: Up to 2 g daily in divided doses.
Lead poisoning: Up to 1 g daily in divided doses.

For children the dose is up to 20 mg/kg/day in divided doses. Gradual introduction of Distamine is *not* advocated in these conditions.

3. *Cystinuria*: A single 500 mg dose on retiring, following free fluids during the day, may effect stone dissolution in a functioning kidney. Otherwise 750 mg–1 g daily in divided doses is generally adequate and it should not be necessary to exceed 2 g daily.

4. *Desensitisation*: No fixed dose regimen. An initial dose of 25 mg daily is suggested, this to be gradually increased in accordance with the response of the patient.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to penicillamine, except in a life-threatening situation.

Side-effects and adverse reactions: Most adverse reactions to Distamine are attributable to its activity as an allergen. Early symptoms of intolerance include nausea, anorexia, vomiting and fever, with or without rash, usually of morbilliform type. Thrombocytopenia and neutropenia may occur at any time and usually respond rapidly to withdrawal of Distamine, although deaths from agranulocytosis and aplastic anaemia have been recorded.

Disturbance of taste is common in the early weeks but usually resolves despite continuation of Distamine therapy. Early transient proteinuria may be observed. After about six months some 20% of patients develop more persistent proteinuria which sometimes becomes progressively heavier, or is accompanied by microscopic haematuria. Nephrotic syndrome may occur. Other disorders of later onset and attributed to Distamine are lupus erythematosus and rheumatoid-like reactions, myasthenia, stomatitis and varied lesions of the skin including pemphigus, though rarely. Goodpasture's syndrome and haemolytic anaemia have been reported.

Precautions: The frequency and severity of the adverse reactions are reduced by gradual introduction and low maintenance doses of Distamine.

White blood cell and platelet counts and tests of the urine for protein and blood are mandatory throughout treatment at not more than monthly intervals. During the first six weeks these should be weekly or fortnightly. A falling platelet or neutrophil count, even within the normal range, over three successive counts indicates withdrawal.

If Distamine is withdrawn because of thrombocytopenia (below 120,000/cumm) or neutropenia (below 2,000/cumm) recovery will be rapid and one further attempt to reinstitute Distamine may then be made. The starting dose should not exceed 250 mg daily and this should be maintained for four weeks before further gradual increases are made.

If proteinuria is detected this must be quantified in a 24-hour collection. Heavy or steadily increasing proteinuria or significant haematuria call for withdrawal of Distamine.

Allergic rash occurring early, unless severe, responds to cyproheptadine and temporary reduction of dose of Distamine.

Copper or zinc supplements are not recommended for prophylaxis or treatment of taste impairment.

Warnings: The safety of Distamine for use during pregnancy has not been established. There have been a

number of successful pregnancies in patients with Wilson's disease with no reports of adverse effects of the fetus.

Patients who have experienced reactions to gold therapy may be particularly prone to Distamine reactions; so that Distamine should be begun with a 125 mg dose which should be increased only at monthly intervals.

Because of the slowness of the response to Distamine existing treatment of rheumatoid arthritis by analgesic; anti-inflammatory drugs or steroids should be maintained and only gradually reduced later.

Distamine forms complexes with certain heavy metals including iron, therefore simultaneous oral therapy should not be given.

Treatment of overdosage: No instance of adverse reaction to an overdose of Distamine has been recorded and no specific measures are indicated.

Pharmaceutical precautions Store in a dry place below 25°C. Keep containers tightly closed.

Legal category POM.

Package quantities

Tablets 50 mg: Bottles of 100.

Tablets 125 mg: Bottles of 100.

Tablets 250 mg: Bottles of 100.

Further information Occasionally patients with rheumatoid arthritis who have responded initially to particular dose begin to relapse. Most of these will respond to a dose increase which should be gradual. Both sero-negative and sero-positive rheumatoid arthritis usually respond to Distamine.

Tablets 250 mg 0006/5008

DISTAQUAINE* V-K

Presentation Phenoxymethylpenicillin Potassium

Tablets BP: containing the equivalent of 125 mg or 250 mg phenoxymethylpenicillin. The 125 mg tablets are white, scored, 8 mm in diameter and marked 'D VK'. The 250 mg tablets are white, scored, 10.5 mm in diameter and marked 'DD KF'.

Syrup: granules for the preparation of Phenoxymethylpenicillin Elixir BPC, 125 mg/5 ml or 250 mg/5 ml. The granules are pale pink, converting to orange liquid on reconstitution.

Elixir: granules for the preparation of Phenoxymethylpenicillin Elixir BPC, 62.5 mg/5 ml. The granules are pale pink, converting to orange liquid on reconstitution.

Uses Penicillin exerts high activity *in vitro* against: staphylococci (except penicillinase-producing strains streptococci (groups A, C, G, H, L and M), pneumococci, *Corynebacterium diphtheriae*, *Bacillus anthracis*, *Actinomyces bovis*, *Streptobacillus moniliformis*, *Listeria monocytogenes*, *Neisseria gonorrhoeae*, *Treponema pallidum*, *Clostridium* species and *Leptospira*.

Phenoxymethylpenicillin and potassium phenoxymethylpenicillin are indicated in the treatment of mild to moderately severe infections associated with microorganisms whose susceptibility to penicillin is within the range of serum levels attained with these dosage forms.

The following infections will usually respond to adequate doses:

Streptococcal infections (without bacteraemia) – mild to moderate infections of the upper respiratory tract, scarlet fever and mild erysipelas.

Vote: Streptococci in groups A, C, G, H, L and M are very sensitive to penicillin. Other groups, including group D (enterococci), are resistant.

Neumococcal infections – mild to moderately severe infections of the respiratory tract.

Staphylococcal infections sensitive to penicillin – mild infections of the skin and soft tissues.

Vote: reports indicate an increasing number of strains of staphylococci resistant to penicillin G, which emphasises the need for culture and susceptibility studies when treating suspected staphylococcal infections.

Fusospirochetosis (Vincent's gingivitis and pharyngitis) – mild to moderately severe infections of the oropharynx usually respond to therapy with oral penicillin.

Prophylactic use – Prophylaxis with oral penicillin has proved effective in preventing recurrence of rheumatic fever and chorea.

Patients with a past history of rheumatic fever receiving continuous prophylaxis may harbour penicillin-resistant organisms. In these patients, the use of another prophylactic agent should be considered.

Vote: Oral penicillin should not be used as adjunctive prophylaxis for genito-urinary instrumentation or surgery, lower intestinal tract surgery, sigmoidoscopy and childbirth.

Dosage and administration For oral administration.

Adults: 125 mg or 250 mg every four to six hours depending on the severity of the condition.

Children over 5 years: The adult dose.

Children 5 years or less: 125 mg every six hours.

Infants (up to 1 year): 62.5 mg every six hours.

In all but the most serious cases, the last dose of the day may be doubled to avoid disturbing sleep. Ideally, each dose should be given half an hour before (or at least three hours after) a meal.

Diluents: For elixir and syrup, where dilution is unavoidable, Syrup BP should be used after the solution has been prepared according to the manufacturer's instructions.

Contra-indications, warnings, etc A previous hypersensitivity reaction to any penicillin is a contra-indication.

Warnings: All degrees of hypersensitivity including fatal anaphylaxis have been observed with oral penicillin. These reactions are more likely to occur in individuals with a history of sensitivity to multiple allergens, and inquiry should be made for such a history before therapy is begun. If an allergic reaction occurs, the drug should be discontinued and the patient treated with the usual agents (e.g. adrenaline and other pressor amines, antihistamines and corticosteroids).

Precautions: Penicillin should be used with caution in individuals with histories of significant allergies and/or asthma.

Oral therapy should not be relied upon in patients with severe illness, or with nausea, vomiting, gastric dilatation, aridospasm or intestinal hypermotility.

Occasionally patients do not absorb therapeutic amounts of orally administered penicillin.

Streptococcal infections should be treated for a minimum of 10 days, and post-therapy cultures should be performed to confirm the eradication of the organisms.

Prolonged use of antibiotics may promote the overgrowth of non-susceptible organisms, including fungi. If superinfection occurs, appropriate measures should be taken.

Adverse reactions: The most common reactions to oral penicillin are nausea, vomiting, epigastric distress, diarrhoea and black, hairy tongue.

Hypersensitivity reactions observed may be skin eruptions, urticaria, reactions resembling serum sickness, chills, fever, oedema, arthralgia, prostration, laryngeal oedema and anaphylaxis. Fever and eosinophilia may frequently be the only reactions observed. Haemolytic anaemia, leucopenia, thrombocytopenia, neuropathy and nephropathy are infrequent reactions and are usually associated with high doses of parenteral penicillin.

Pharmaceutical precautions **Tablets:** Store in a cool (6°–15°C), dry place. Protect from moisture.

Syrup and Elixir: Store in a cool place (6°–15°C) and protect from moisture. Reconstituted preparations should be stored in a cool place and used within seven days.

Legal category POM.

Package quantities

Tablets 125 mg: Bottles of 100 and 500.

Tablets 250 mg: Bottles of 100, 500 and 1,000.

FENOPRON[®] FENOPRON D[®]

Presentation *Fenopron* – Fenopron Calcium Tablets BP, each containing fenopron calcium equivalent to 300 mg fenopron or 600 mg fenopron.

Fenopron D – Dispersible tablets each containing fenopron calcium equivalent to 300 mg fenopron.

The 300 mg tablets are orange, elliptical, 14 mm long and marked DISTA 4019.

The 600 mg tablets are orange para-capsule, scored, 20 mm long and marked DISTA 4021.

The dispersible tablets are white, biconvex, triangular/trochoid, 14 mm long and marked FND.

Uses For the treatment of osteoarthritis, rheumatoid arthritis and ankylosing spondylitis. For the relief of mild/moderate pain.

Dosage and administration For oral administration to adults only, and not recommended for administration

to children. Stir the dispersible tablets in half a cup of water.

Dosage: 300–600 mg three or four times a day.

300 mg tablet: Recommended initial dosage is 2 tablets three times per day, then adjusted to the needs of the patient.

600 mg tablet: Recommended initial dosage is 1 tablet three times per day, plus one at night if necessitated by a more severe condition. The dosage may then be adjusted to the needs of the patient.

Dispersible tablets: Recommended initial dosage is 2 tablets three times per day, then adjusted to the needs of the patient.

The maximum daily dose should not exceed 3 g.

Gastro-intestinal intolerance can be minimised by taking Fenopron with milk or at meal times.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the drug. Active peptic ulceration.

Warnings: Adverse effects may include gastro-intestinal intolerance and episodes of bleeding. Although fenopron has been associated with less gastro-intestinal microbleeding than aspirin, patients with a history of peptic ulcer or gastro-intestinal bleeding should be closely supervised during fenopron therapy.

Bronchospasm may be precipitated in patients suffering from, or with a previous history of, bronchial asthma or allergic disease.

Although cross-sensitivity has not been established, the drug should not be given to patients in whom salicylates induce the syndrome of asthma, rhinitis or urticaria.

Usage in pregnancy: The safety of fenopron for use during pregnancy or lactation has not been established; therefore it should not be administered to pregnant women or nursing mothers unless the potential benefits clearly outweigh any potential risk. Animal studies showed prolongation of parturition.

Precautions: Because of its affinity for albumin, fenopron may displace other drugs from their binding sites, and this may lead to drug interaction. In patients receiving coumarin-type anticoagulants, the addition of fenopron could prolong the prothrombin time. Patients receiving hydantoins or sulphonylureas should be carefully monitored.

When aspirin and fenopron are administered concurrently, plasma concentrations of fenopron are reduced. It may be advisable to discontinue the concomitant use of aspirin to maximise the beneficial effects of fenopron. However, single or intermittent doses of aspirin may be administered if they are indicated.

Since fenopron is eliminated primarily by the kidney, the drug should not be administered to patients with significantly impaired renal function.

Patients with initial low haemoglobin values who are receiving long-term therapy should be monitored, as transient reduction of haemoglobin and haematocrit values due to fenopron have been reported.

Elevation of AST (SGOT), LDH and ALP levels have been reported occasionally, and it is therefore recommended that fenopron be discontinued if any significant liver abnormalities occur.

Side-effects: *Gastro-intestinal* – These are the most commonly observed side-effects and include dyspepsia, constipation, diarrhoea, ulceration of the buccal mucosa, nausea, vomiting, anorexia and occult blood in the stool.

Cases of peptic ulceration, including some complicated by bleeding, have occurred.

Renal – Rare cases of acute renal insufficiency, in association with allergic nephritis, nephrosis or papillary necrosis, have been reported. As a general rule, these are reversible on withdrawal of the drug. Episodes of dysuria, cystitis and haematuria have occurred.

Haematological – Various syndromes involving the bone marrow have been reported rarely; thrombocytopenia, pancytopenia and aplastic anaemia have occurred.

Allergic – Pruritis, rash, urticaria, Stevens-Johnson syndrome and angio-neurotic oedema have been reported.

Neurological – Reactions reported include headache, somnolence, dizziness, tremor, confusion and insomnia.

Miscellaneous – Tinnitus, hearing decrease, amblyopia, blurred vision, palpitations, increased sweating, nervousness and peripheral oedema have been reported.

Overdosage: Information is available on two cases of intentional overdose. A patient who ingested 7.5 g fenopron developed severe lower abdominal pain, scrotal pain, burning on micturition, haematuria and proteinuria. All symptoms subsided within forty-eight hours.

A second patient who ingested 33 g fenopron over a seven-hour period developed abdominal pain followed by vomiting, and excessive perspiration. She was anuric for twenty-four hours, despite supportive therapy, and during this time developed severe headache and tinnitus. Subsequent urinalysis indicated haematuria. Symptoms gradually resolved and recovery was uneventful.

Treatment: Standard therapy to evacuate gastric contents and to support vital functions should be employed. Since fenopron is acidic and is excreted in the urine, it would seem theoretically beneficial to try forced alkaline diuresis.

Pharmaceutical precautions 300 mg and 600 mg tablets: Store in a cool (6°–15°C), dry place.

Dispersible tablets: Keep tightly closed. Store in a cool dry place. Dispense in moistureproof container.

Legal category POM.

Package quantities

HAELAN*

HAELAN-X*

Presentation *Haelan*: Collapsible tubes containing 0.0125% flurandrenolone in cream or ointment base. The cream is white in colour and the ointment is translucent.

Haelan-X: Collapsible tubes containing 0.05% flurandrenolone in cream or ointment base. The cream is white in colour and the ointment is translucent.

Uses Topical steroid. For the topical management of those dermatological disorders which may be expected

to respond to corticosteroids and in the case of Haelan, those which may require prolonged application.

Dosage and administration *Cream:* For moist weeping lesions the cream should be applied gently to the affected area two or three times daily.

Ointment: For dry, scaly lesions, the ointment should be applied as a thin film to the affected area two or three times daily.

Dilution is not recommended, but if considered necessary Aqueous Cream BP may be used for the creams and White Soft Paraffin BP for the ointments.

Contra-indications, warnings, etc

Contra-indication: Not to be used in the presence of tuberculosis of the skin.

Warnings: Preparations of Haelan are not intended for ophthalmic use.

A few individuals may be sensitive to Haelan. If any reaction indicating sensitisation is observed discontinue the use of the products.

In infants, long-term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

Usage in pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of these findings to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Neither local nor systemic side-effects have been reported so far from the use of either Haelan Cream or Ointment. Evidence of absorption of the steroid has been observed only when a much higher concentration has been used under an occlusive dressing.

Pharmaceutical precautions No special pharmaceutical precautions. See 'Administration' for diluents.

Legal category POM.

Package quantities

Haelan Cream (0.0125% flurandrenolone): Tubes of 10 g.

Haelan Ointment (0.0125% flurandrenolone): Tubes of 10 g.

Haelan-X Cream (0.05% flurandrenolone): Tubes of 5 g.

Haelan-X Ointment (0.05% flurandrenolone): Tubes of 5 g.

Further information As with all topical steroids the activity can be enhanced by the use of occlusive dressings. Preparations of Haelan are recommended only as a supplement to, and not as a substitute for, reparations (lotions, wet dressings, etc.) used in the conventional management of skin lesions.

HAELAN-C*

Presentation Collapsible tubes containing 0.0125% flurandrenolone with the addition of 3% Cliquinol BP cream or ointment base. The cream is white in colour and the ointment is translucent.

Uses Topical steroid with antibacterial added. For the topical management of those dermatological disorders complicated by bacterial or fungal infection and which may be expected to respond to corticosteroids, particularly those requiring prolonged application.

Dosage and administration *Cream:* For moist weeping lesions, the cream should be applied gently to the affected area two or three times a day.

Ointment: For dry, scaly lesions, the ointment should be applied as a thin film to the affected area two or three times a day.

Dilution is not recommended, but if considered necessary Aqueous Cream BP may be used for the creams and White Soft Paraffin BP for the ointments.

Contra-indications, warnings, etc

Contra-indication: Not to be used in the presence of tuberculosis of the skin.

Side-effects and adverse reactions: Neither local nor systemic side-effects have been reported so far from the use of either Haelan-C Cream or Ointment. Evidence of absorption of the steroid has been observed only when a much higher concentration has been used under an occlusive dressing.

A few individuals may be sensitive to Haelan-C. If any reaction indicating sensitisation is observed, discontinue the use of the product.

Warnings:

1. Preparations of Haelan-C are not intended for ophthalmic use.

2. In infants, long-term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

3. Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of these findings to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

4. Haelan-C may cause staining of the hair, clothing and many fabrics.

Pharmaceutical precautions No special pharmaceutical precautions. See 'Administration' for diluents.

Legal category POM.

Package quantities

Haelan-C Cream (0.0125% flurandrenolone with 3% Cliquinol BP): Tubes of 30 g.

Haelan-C Ointment (0.0125% flurandrenolone with 3% Cliquinol BP): Tubes of 30 g.

Further information When secondary bacterial and fungal infection of the skin is present or suspected in an otherwise steroid responsive skin condition, Haelan-C should be used and treatment resumed with Haelan after the infection has been controlled. Such patients must be under constant medical observation.

Haelan-C Cream 0006/5018

Haelan-C Ointment 0006/5021

HAELAN* Tape

Presentation A translucent, polythene adhesive film impregnated with 4 mcg flurandrenolone per square centimetre and protected by a removable paper liner.

Uses Occlusive topical steroid. Adjunctive therapy for chronic recalcitrant dermatoses that may respond to topical corticosteroids, and particularly dry, scaling and localised lesions.

Dosage and administration For application to the skin, which should be clean, dry and shorn of hair. In most instances the tape need only remain in place for 12 out of 24 hours.

Cosmetics may be applied over the tape.

Application: The tape is cut so as to cover the lesion and a $\frac{1}{4}$ inch margin of normal skin. Corners should be rounded off. After removing the lining paper, the tape is applied to the centre of the lesion with gentle pressure and worked to the edges, avoiding excessive tension of the skin. If longer strips of tape are to be applied, the lining paper should be removed progressively.

Contra-indications, warnings, etc

Contra-indications: Chicken pox, vaccinia, tuberculosis of the skin and hypersensitivity to any of the components.

Side-effects and adverse reactions: Irritation, itching, dryness and folliculitis may be troublesome. Maceration of the skin, secondary infection, skin atrophy, striae and miliaria are more likely to occur under occlusion. In their presence the use of the tape should be discontinued. If extensive areas are treated there may be undue systemic absorption, especially in infants, where long-term continuous use should be avoided.

Warnings: Not advocated for acute and weeping dermatoses.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of these findings to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Pharmaceutical precautions Store in a dry place at room temperature, below 25°C.

Legal category POM.

Package quantities Single rolls of tape, 7.5 cm wide, 200 cm long.

Further information Nil.

Product licence number 0006/5158.

ILOSONE®

Presentation Capsules each containing the equivalent of 250 mg erythromycin base as Erythromycin Estolate BP. The capsules are ivory/red, marked 'DISTA' and are 2.1 cm long.

Tablets each containing the equivalent of 500 mg erythromycin base as Erythromycin Estolate BP. The tablets are pink, para-capsule shaped, 1.9 cm long and coded DISTA D1.

Ready-mixed suspension, each 5 ml containing the equivalent of 125 mg erythromycin base as Erythromycin Estolate BP. The suspension is orange coloured.

Ready-mixed suspension forte, each 5 ml containing the equivalent of 250 mg erythromycin base as Erythromycin Estolate BP. The suspension is orange coloured.

Uses Antibiotic. Erythromycin is indicated in the treatment of conditions associated with the following micro-organisms:

Streptococcus pyogenes (group A beta-haemolytic): Upper and lower respiratory tract, skin, and soft tissue infections of mild to moderate severity.

Alpha-haemolytic streptococci (viridans group): Short term prophylaxis against bacterial endocarditis prior to dental or other operative procedures in patients with a history of rheumatic fever or congenital heart disease who are hypersensitive to penicillin.

Staphylococcus aureus: Acute infections of skin and soft tissue which are mild to moderately severe. Resistance may develop during treatment.

Streptococcus pneumoniae: Upper and lower respiratory tract infections of mild to moderate severity.

Mycoplasma pneumoniae: Primary atypical pneumonia when due to this organism.

Bordetella pertussis: When given early after exposure to whooping cough, erythromycin may reduce the risk of development of classical symptoms.

Treponema pallidum: Erythromycin is an alternative choice of treatment for syphilis in penicillin-allergic patients.

Corynebacterium diphtheriae: As an adjunct to antitoxin, to prevent establishment of carriers, and to eradicate the organism in carriers.

Corynebacterium minutissimum: In the treatment of erythrasma.

Entamoeba histolytica: In the treatment of intestinal amoebiasis only. Extra-enteric amoebiasis requires treatment with other agents.

Listeria monocytogenes: Infections due to this organism.

Legionnaires' disease: Although no controlled clinical studies have been conducted, *in vitro* and limited preliminary clinical data suggest that erythromycin may be effective in treating Legionnaires' disease.

Dosage and administration For oral administration.

Adults: The usual dose is 250 mg every six hours. This may be increased up to 4 g or more per day according to the severity of the infection.

Children: Age, weight, and severity of the infection are important factors in determining the correct dosage. The usual range is 20–50 mg/kg/day in divided doses.

For mild to moderate infections

Body weight	Total daily dose
10 kg or less	250 mg
10–18 kg	375 mg
18–25 kg	500 mg
25–36 kg	750 mg
More than 36 kg	1000 mg (adult dose)

For more severe infections these dosages may be doubled.

If administration on a twice daily schedule is desirable one-half of the total daily dose may be given every 12 hours.

Streptococcal infections: In the treatment of group A beta-haemolytic streptococcal infections, a therapeutic dosage of erythromycin should be administered for at least 10 days. In continuous prophylaxis of streptococcal infections in persons with a history of rheumatic heart disease, the dosage is 250 mg twice daily.

When Ilosone is used prior to surgery to prevent endocarditis caused by alpha-haemolytic streptococci (viridans group) a recommended schedule for adults is:

1 g pre-operatively and 500 mg every six hours for eight doses post-operatively: for children, 30–50 mg/kg/day divided into three or four evenly spaced doses.

Pertussis: Doses of erythromycin estolate utilised in reported clinical studies were 40–50 mg/kg/day, given in divided doses for five to 14 days.

Syphilis: A regimen of 20 g of erythromycin estolate in divided doses over a period of 10 days has been shown to be effective.

Amoebic dysentery: Dosage for adults is 250 mg four times daily for 10 to 14 days; for children, 30–50 mg/kg/day in divided doses for 10 to 14 days.

Legionnaires' disease: Although optimum regimens have not been established, 1–4 g daily in divided doses has been utilised in reported clinical studies.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to erythromycin.

Patients who have previously developed jaundice or who have pre-existing liver disease or dysfunction.

Warnings: The administration of erythromycin estolate has been associated with the infrequent occurrence of reversible cholestatic hepatitis. Hepatic dysfunction with or without jaundice has occurred, chiefly in adults. It may be accompanied by malaise, nausea, vomiting, abdominal colic and fever. In some instances severe abdominal pain may simulate the pain of biliary colic, pancreatitis, perforated ulcer, or an acute abdominal surgical problem. In other instances, clinical symptoms and results of liver function tests have resembled findings in extrahepatic obstructive jaundice. Laboratory findings have been characterised by abnormal hepatic function test values, peripheral eosinophilia and leucocytosis. If he above findings occur, discontinue Ilosone promptly.

Initial symptoms have developed in some cases after a few days of treatment, but generally have followed one or two weeks of continuous therapy. Symptoms reappear promptly, usually within 48 hours, after the drug is re-administered to sensitive patients. The syndrome seems to result from a form of sensitisation, occurs chiefly in adults, and has been reversible when medication is discontinued.

Usage in pregnancy: Although laboratory and clinical studies have shown no evidence of teratogenicity, caution should be exercised when prescribing for the pregnant patient.

Precautions: The use of erythromycin in patients who are receiving concomitant high doses of theophylline may be associated with an increase in serum theophylline levels and potential theophylline toxicity. If symptoms of toxicity develop, the dose of theophylline should be reduced.

During prolonged or repeated therapy, there is a possibility of overgrowth of nonsusceptible bacteria or fungi. If such infections arise, the drug should be discontinued and appropriate therapy instituted.

Side-effects: The most frequent side-effects of erythromycin preparations are gastro-intestinal (e.g. abdominal cramping and discomfort) and are dose-related. Nausea, vomiting and diarrhoea occur infrequently with usual oral doses.

Mild allergic reactions, such as urticaria and other skin rashes, have occurred. Serious allergic reactions, including anaphylaxis, have been reported.

Overdosage: Symptoms – nausea, vomiting and diarrhoea.

Treatment: General management may consist of supportive therapy.

Pharmaceutical precautions Capsules and tablets: Keep container tightly closed and store in a cool place (6°–15°C).

Suspensions: Keep container tightly closed and protect from light. Store in a cool place. Shake well before use. For dilution, use Syrup BP, and when diluted use within 14 days.

Legal category POM.

Suspension 250 mg/5 ml 0006/5024

NAPSALGESIC*

Presentation Tablets containing 50 mg Dextropropoxyphene Napsylate BP (equivalent to approximately 32.5 mg dextropropoxyphene hydrochloride or 30 mg dextropropoxyphene base) with 500 mg Aspirin PhEur. The tablets are pale yellow, pillow-shaped, marked 'DP' and are 16 mm in length.

Uses Analgesic. For the treatment of pain such as that of rheumatic conditions, especially where there is a need for additional analgesia to that provided by aspirin alone, or where high doses of aspirin have to be reduced to avoid side-effects.

Dosage and administration For oral administration to adults only.

Dosage: The usual dose is 4–6 tablets daily in divided doses, and should not normally be exceeded.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to dextropropoxyphene or aspirin, active peptic ulceration and haemophilia.

Warnings: Dextropropoxyphene is an analgesic with CNS depressant properties and should be used with caution in patients who are receiving other CNS depressant drugs, as an additive effect may occur. Patients should be warned to avoid alcohol.

As with other drugs which affect the CNS, care should be taken when prescribing for patients with personality or other psychological disorders.

Tolerance, psychological and physical dependence may rarely occur.

Like other centrally acting drugs, dextropropoxyphene may impair patients' mental and physical reactions in the performance of potentially hazardous tasks (e.g. in driving ability, operation of machinery, etc.) to a varying extent, depending on dosage and individual susceptibility.

Salicylates should be used with caution in patients with asthma or coagulation abnormalities. They may also induce gastro-intestinal haemorrhage, occasionally major.

Use in pregnancy: The safety of Napsalgesic for use during pregnancy has not been established. Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term.

Precautions: Aspirin may enhance the effect of anti-coagulants, inhibit the action of uricosuric agents, precipitate bronchospasm or induce attacks of asthma in susceptible individuals.

Side-effects: Side-effects such as dizziness, sedation, nausea and vomiting seem to be more prominent in ambulatory than in non-ambulatory patients, and some of these side-effects may be alleviated if the patient lies down.

Other reported side-effects include constipation, abdominal pain, skin rashes, lightheadedness, weakness, euphoria, dysphoria and minor visual disturbances.

Overdosage: The chronic ingestion of dextropropoxyphene in doses exceeding 720 mg (as base) per day has caused toxic psychoses and convulsions.

Symptoms of acute toxicity may be rapid in onset, with the danger of respiratory arrest. Other recognised manifestations include respiratory depression, coma, circulatory collapse, pulmonary oedema, convulsions and cardiac arrhythmias.

Deterioration may be rapid, with fatal outcome.

The clinical picture may be complicated by salicylism.

Treatment: Primary attention should be given to the re-

establishment of adequate respiratory exchange through provision of a patent airway and institution of assisted or controlled ventilation. The narcotic antagonist naloxone is a specific antidote against the respiratory depression produced by dextropropoxyphene. An appropriate dose of this antagonist should be administered, preferably by the intravenous route, simultaneously with efforts at respiratory resuscitation. Repeated doses of the antagonist may be necessary over a prolonged period due to the slow elimination of dextropropoxyphene. In addition to the use of a narcotic antagonist, the patient may require careful titration with an anticonvulsant to control seizures. Analeptic drugs (for example, caffeine or amphetamine) should not be used because of their tendency to precipitate convulsions.

Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Gastric lavage may be helpful. Activated charcoal can absorb a significant amount of ingested dextropropoxyphene. Dialysis is of little value in poisoning by dextropropoxyphene alone. Salicylates are dialysable.

Pharmaceutical precautions Store in a cool (6°–15°C), dry place. Keep containers tightly closed.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

ALLPYRAL* ALLERGEN EXTRACTS

Presentation *Ingredients:* An Allpyral Allergen Extract is a sterile, pyridine-extracted, alum-precipitated antigen complex in suspension, in an aqueous solution of 0.9% saline containing 0.4% phenol as a preservative. Allpyral Allergen Extracts are standardised on a protein nitrogen unit (PNU) basis.

Allpyral Allergen Extracts are prepared *either* according to the specific sensitivities of individual patients (these Extracts are designated Allpyral-Specific), *or* as standard extracts of pollens of five common grasses (these Extracts are designated Allpyral-G).

Allpyral-Specific Allergen Extracts are prepared from one or more of the following source materials (subject to conditions given in Notes 1-6):

Pollens

Grass mix (see Note 1)	<i>Ash</i>	} Tree mix (see Note 3)
Plantain	<i>Birch</i>	
Mugwort	<i>Elm</i>	
Nettle	<i>Oak</i>	
Flower mix compositae (see Note 2)	<i>Plane</i>	

Beech
Hazel
Alder
Willow
Sycamore

Other inhalants

D. pteronyssinus	Feather mix (see Note 5)
Mite Fortified house dust (see Note 4)	Rye flour
House dust	Wheat flour
Cat	Horse
Cow	Rabbit
Dog	Sheep wool

Moulds

Botrytis cinerea
Dry rot (*Merulius lacrymans*)
Phoma betae
Sporobolomyces roseus
Candida albicans
Fusarium oxysporum
Helminthosporium sativum
Mucor racemosus

<i>Alternaria tenuis</i>	} Mould mix (see Note 3)
<i>Aspergillus fumigatus</i>	
<i>Dadosporium herbarum</i>	
<i>Penicillium notatum</i>	

Pullularia pullulans
Rhizopus nigricans

Stinging insects (see Note 6)

Nasp Bee

Note 1. Grass mix contains extracts of the pollens of cocksfoot, meadow fescue, perennial rye, timothy, and Yorkshire fog.

These extracts are available *only* as constituents of Allpyral-Specific (grass mix) and *not* as individual extracts.

Note 2. Flower mix compositae contains extracts of the pollens of golden rod, Michaelmas daisy, dahlia and chrysanthemum.

These extracts are available *only* as constituents of Allpyral-Specific (flower mix) and *not* as individual extracts.

Note 3. Those individual tree pollens and moulds underlined are available *either* individually *or* as constituents of tree mix and mould mix.

Note 4. D. pteronyssinus and Mite Fortified house dust are available *only* as individual extracts and *not* mixed with any other extract.

Note 5. Feather mix contains extracts of the feathers of chicken, duck and goose. These are available *only* as constituents of Allpyral-Specific (feather mix) and *not* as individual extracts.

Note 6. The stinging-insect extracts of wasp and bee are available *either* individually *or* as a wasp/bee mixture, but *not* mixed with any other allergens.

Allpyral-G Allergen Extract contains extracts of the pollens of cocksfoot, meadow fescue, perennial rye, timothy, and Yorkshire fog. Allpyral-G is recommended for the treatment of classical hay fever and/or grass pollen asthma. (This is a standard item available immediately from stock.)

Form and appearance: The colour of Allpyral Allergen Extracts depends upon the type of allergens used and the strength of extract in each vial. Grass pollen extracts range from pale to olive green, extracts of house dust and mite fortified house dust range from grey to black, mould extracts range from clear to pale brown, epithelial extracts range from clear to milky white, tree pollen extracts range from olive to dark green, and D. pteronyssinus extracts range from clear to milky white. Allpyral Allergen Extracts are available in three types of treatment set:

1. Initial Treatment Sets consist of 3 colour-coded, graduated-strength vials.

Vial No. 1 (Green Label) contains extract of 100 PNU/ml strength.

Vial No. 2 (Blue Label) contains extract of 1,000 PNU/ml strength.

Vial No. 3 (Black Label) contains extract of 10,000 PNU/ml strength.

(D. pteronyssinus only - Vial No. 3 (Brown Label) contains extract of 4,000 PNU/ml strength).

2. Special Dilution Treatment Sets consist of 1 vial containing extract of 10 PNU/ml strength. This treatment set may be required for use *before* the Initial Treatment Set in certain cases (see 'Dosage and administration' below), and will be supplied on *request* with the Initial Treatment Set.

3. Maintenance Treatment Sets consist of 1 vial (Black Label) containing extract of 10,000 PNU/ml

strength (D. pteronyssinus only – Maintenance Sets consist of 3 × 2 ml vials (Brown Labels) containing extracts of 4,000 PNU/ml strength) (see 'Dosage and administration' below).

All treatment sets are supplied complete with sufficient sterile disposable syringes and needles for the course ordered.

Uses Indications

Allpyral-Specific: For the hyposensitisation of patients whose allergies have been determined by case history and confirmed by skin testing. (To ensure conformity between the results of skin-testing and subsequent treatment, it is recommended that Dome[®] Glycerinated Skin Testing Solutions are used. There is a Dome Glycerinated Skin Testing Solution for each of the Allpyral Allergen Extracts listed above with the exception of bee and wasp extracts; the diagnostic solutions and the treatment extracts are prepared from common source materials.)

Allpyral-G: For the hyposensitisation of patients known to suffer from classical hay fever and/or grass pollen asthma.

Dosage and administration Allpyral Allergen Extracts should be administered only by subcutaneous injection. Patients sensitive to seasonal allergens should be treated *pre-seasonally*, in order to ensure that treatment is completed before the seasonal allergen becomes airborne.

Patients sensitive only to perennial, i.e. non-seasonal, allergens may be treated at any time of the year.

Each Allpyral-Specific Treatment Set is supplied with a dosage schedule appropriate to the individual patient's requirements, together with complete instructions on administration. (Each such treatment set and its accompanying dosage instructions are prepared from the information given on the Allpyral Order Form by the prescribing physician.)

Each Allpyral-G Treatment Set is supplied with alternative dosage schedules from which the physician should select the dosage appropriate to the particular patient. Complete instructions on administration are also supplied.

SEASONAL ALLERGENS

Initial treatment: Each year's treatment with Allpyral Allergen Extracts should always commence with an Initial Treatment Set.

Initial treatment on a pre-seasonal basis consists of a course of 9 subcutaneous injections from the Allpyral-G or Allpyral-Specific Initial Treatment Set.

This course should be completed not less than three weeks before the particular allergen becomes airborne. Clinical evidence suggests that best results are obtained if the pre-seasonal course is timed to end as close as possible to the date three weeks before pollination.

It is recommended that children under 14 in the first year of treatment should be treated according to either the 'Extremely Sensitive' or the 'Very Sensitive' dosage schedules. For extremely sensitive patients a Special Dilution Treatment Set can be supplied *on request*. This should precede administration of the Initial Treatment Set.

Increasingly, clinical experience indicates that if pre-seasonal hyposensitisation is repeated for three consecutive years, long-lasting relief may be expected, rendering treatment in subsequent years unnecessary. *For each year of treatment an Initial Treatment Set will be required.* The previous year's treatment should have reduced the

patient's degree of sensitivity and, therefore, in the second and third years of treatment the dosage schedule should be adjusted accordingly (i.e. from 'Very Sensitive' to 'Moderately Sensitive', or from 'Moderately Sensitive' to 'Mildly Sensitive'), dependent upon the patient's progress.

Maintenance treatment: Maintenance treatment is advisable in cases where pre-seasonal initial treatment has been completed long before the onset of pollination, e.g. in the case of grass pollen, if the course has finished in February (the grass pollen season usually starts in late May). Treatment with an Allpyral Maintenance Set involves repeat injections of the top dose achieved on the preceding initial treatment course, given at four to six weekly intervals until three weeks before the onset of pollination.

Not more than six weeks should elapse between the last injection of the initial treatment course and the first maintenance injection, or between subsequent maintenance injections. If more than six weeks elapse, then the dosage should be reduced accordingly.

PERENNIAL ALLERGENS

Initial treatment: Treatment with Allpyral Allergen Extracts should always commence with an Initial Treatment Set.

Initial treatment consists of 9–10 subcutaneous injections from the Allpyral-Specific Initial Treatment Set. Where only perennial or 'non-seasonal' allergens are involved, treatment with Allpyral-Specific may be started at any time of the year. It is recommended that children under 14 in the first course of treatment should be treated according to either the 'Extremely Sensitive' or the 'Very Sensitive' dosage schedules. For extremely sensitive patients a Special Dilution Treatment Set can be supplied *on request*. This should precede administration of the Initial Treatment Set.

Maintenance treatment: Maintenance treatment is intended to maintain the protection afforded by the initial treatment course and should only be given where an initial treatment course has previously been completed. Maintenance treatment consists of repeat injections of the top dose achieved on the initial treatment course, given every four to six weeks.

Not more than six weeks should elapse between the final injection of the initial treatment course and the first maintenance injection, or between subsequent maintenance injections. If more than six weeks elapse, then the dosage should be reduced accordingly.

Other advice on the administration of Allpyral Allergen Extracts is as follows:

1. Observe the usual sterile techniques.
2. Do not inject intravenously.
3. Shake the vial well before withdrawing the dose.

Where two different courses are being given concurrently the two extracts must *never* be mixed within the same syringe. Injections of the two extracts may be given at the same visit, but in opposite arms.

Alternatively, the normal weekly interval between injections may be increased to two weeks, so that the two courses can be given on alternate weeks (i.e. one course on weeks 1, 3, 5, 7, etc., the other course on weeks 2, 4, 6, 8, etc.).

For recommendations concerning dilution see 'Pharmaceutical precautions' below.

Contra-indications, warnings, etc

Contra-indications: Whilst no adverse reactions have

been reported, it is not considered advisable to administer Allpyral Allergen Extracts during pregnancy.

Precautions: Patients should be detained in the surgery for 15 minutes following each injection, and should be advised not to take any strenuous exercise for some hours.

Adrenaline Injection BP should always be available when administering hyposensitisation therapy.

Overdosage: See 'Main side-effects/adverse reactions' below.

Main side-effects/adverse reactions: As with all forms of hyposensitisation therapy the possibility of reactions in very sensitive individuals cannot be ruled out. This risk is considerably reduced in the case of Allpyral Allergen Extracts, since the antigens are slowly released from the site of injection.

In the event that a constitutional or systemic reaction should occur, this will generally appear slowly and gradually in three to six hours after the injection, and may last for two to four days due to continued slow release of the antigen. Such reactions are rarely critical, and are usually readily controlled with antihistamines. However, itching and swelling could remain for several days, and the patient should be supplied with medication and information to prevent undue apprehension. The dose of antigen to be injected at the next visit should be reduced.

In the case of a moderate local reaction at the site of injection, the same dose should be repeated at the next visit and increased cautiously thereafter.

In the case of a severe local reaction, a tourniquet should be applied to the arm above the site of injection, 0.2–0.3 ml of Adrenaline Injection BP should be injected near the site of injection, and 0.2 ml into the opposite arm. The tourniquet is then gradually released. The dose at the next visit should be reduced.

A general reaction may require a subcutaneous injection of 0.5 ml of Adrenaline Injection BP, repeated as necessary. Additionally, the injection of an antihistamine or an anti-inflammatory steroid may be considered.

Pharmaceutical precautions *Storage:* Store between 2°C and 8°C. Do not freeze.

Dilution: Allpyral Allergen Extracts are supplied ready or use. It is important that, in the event of a pharmacist or physician wishing to dilute an Allpyral Allergen Extract, only diluent supplied for this purpose by Dome should be used. Failure to observe this recommendation may adversely affect the integrity of the Allpyral Allergen Extract, thereby reducing its safety.

Legal category POM.

Package quantities Initial Treatment Sets consist of three colour-coded, graduated-strength vials.

Special Dilution Courses consist of 1 vial.

Maintenance Treatment Sets consist of 1 (top-strength) vial. (D. pteronyssinus only – 3 top-strength vials.) For details of PNU strengths please see 'Presentation – Form and appearance' above.

All Allpyral Allergen Extracts are supplied complete with the appropriate dosage schedule and a sufficient quantity of sterile, disposable syringes and needles for the course.

Further information Allpyral Allergen Extracts are prepared by a process which minimises residual free allergen, and allows slow absorption from the site of

injection. Thus fewer severe reactions, both local and systemic, are experienced than with aqueous extracts, and fewer injections are required.

Treatment with Allpyral Allergen Extracts reduces the patient's hypersensitivity, thereby dealing with the cause of his allergic symptoms. Thus Allpyral Allergen Extracts provide prophylactic rather than palliative therapy.

Product licence number 0055/5001.

DTIC-DOME*

Presentation *Active ingredients:* 5-(3,3-dimethyl-1-triazeno) imidazole-4-carboxamide prepared as the citrate salt (dacarbazine).

100 mg and 200 mg vials of sterile dacarbazine.

DTIC-Dome is a colourless to ivory-coloured solid to be reconstituted with Water for Injections BP.

Uses *Actions:* Although the exact mechanism of action of dacarbazine is unknown, three hypotheses have been offered:

1. Inhibition of DNA synthesis by acting as a purine analogue.
2. Action as an alkylating agent.
3. Interaction with SH groups.

The volume of distribution of DTIC-Dome exceeds body water content, suggesting localisation in some body tissues. DTIC is only slightly (approximately 5%) protein bound. Its plasma half life after i.v. administration is approximately 35 minutes. After 6 hours in animal study, approximately 46% of radiolabelled dose was recovered from the urine. Of this 46% almost half was unchanged DTIC and a like quantity was amino-imidazole carboxamide, a metabolite. DTIC is subject to renal tubular secretion rather than glomerular filtration.

Indications: Metastatic Malignant Melanoma.

Sarcoma.

Hodgkin's Disease.

In addition, DTIC-Dome has been shown when used in combination with other cytotoxic agents, to be of value in treatment of other malignant diseases including: Carcinoma of colon, ovary, breast, lung.

Testicular teratoma.

Solid tumours in children.

Dosage and administration *Standard dose:* The following dosage schedules are recommended:

1. 2.0–4.5 mg/kg/day for 10 weeks, which may be repeated at 4 week intervals.
2. 250 mg/m²/day for 5 days, which may be repeated at 3 week intervals.
3. A further alternative is to administer the total schedule dose on the first day.

Other schedules may be used at the discretion of the prescribing physician.

Children: The dosage for children is calculated on a mg/kg or mg/m² basis as per the standard dosage.

Administration: DTIC-Dome 100 mg and 200 mg vials are reconstituted with 9.9 ml and 19.7 ml, respectively, of Water for Injections BP. The resulting solution contains an equivalent of 10 mg/ml of dacarbazine. After the solution has been prepared, the calculated dose is drawn into a syringe and injected intravenously. Injection may be completed in one or two minutes.

If desired, the reconstituted solution may be further diluted with 125–250 ml of Dextrose Injection BP 5% or

Sodium Chloride Injection BP 0.9% and administered by intravenous infusion over a period of 15 to 30 minutes.

Contra-indications, warnings, etc DTIC-Dome is contra-indicated in patients who have demonstrated a hypersensitivity to it in the past.

This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding.

Studies have demonstrated this agent to have a carcinogenic and teratogenic effect when used on animals.

DTIC-Dome should be administered preferably to patients who are hospitalised and who can be observed carefully and frequently during and after therapy, with particular reference to the haemopoietic system.

Care must be taken to avoid extravasation of the drug subcutaneously during intravenous administration as this may result in tissue damage and severe pain.

Users should avoid contact of DTIC-Dome with the skin and eyes when reconstituting or administering.

It is recommended that DTIC-Dome be administered under the supervision of a physician experienced in the use of cancer chemotherapeutic agents. Since facilities for necessary laboratory studies must be available, hospitalisation is recommended.

Haemopoietic depression is the most common toxic side effect of DTIC-Dome and involves primarily the leucocytes and platelets, although mild anaemia may sometimes occur. Leucopenia and thrombocytopenia may be severe enough to cause death. The possible bone marrow depression requires careful monitoring of white blood cell, red blood cell and platelet levels. Haemopoietic toxicity may warrant temporary suspension or cessation of DTIC-Dome therapy.

Symptoms of anorexia, nausea and vomiting are the most frequently noticed side-effects. Over 90% of patients are affected with the first few doses. The vomiting lasts for 1–12 hours and may be completely but unpredictably palliated by phenobarbital and/or prochlorperazine. Rarely, DTIC-Dome causes diarrhoea. Some helpful suggestions include restricting the patient's oral intake of fluids and food for 4–6 hours prior to treatment. The rapid toleration of these symptoms suggests a central nervous system mechanism, and usually these symptoms subside after the first 1 or 2 days.

Infrequently, some patients have experienced an influenza-like syndrome of fever to 39°C, myalgias and malaise. This syndrome occurs usually after large single doses and approximately 7 days after treatment with DTIC-Dome and lasts 7–21 days, and may recur with successive treatments.

Alopecia has been noted as has facial flushing and facial paraesthesia.

Hepatic toxicity with hepatic necrosis has been extremely rare and has only been observed in patients with advanced malignancy when DTIC-Dome has been administered concomitantly with other anti-neoplastic drugs and when the drug has been used alone in the presence of already existing hepatic pathology.

Anaphylaxis can occur very rarely following administration of DTIC-Dome.

Erythematous and urticarial rashes have been observed infrequently after administration of DTIC-Dome.

Rarely photosensitivity reactions may occur.

Pharmaceutical precautions Store in a refrigerator between 2° and 8°C.

DTIC-Dome, like all triazenes is sensitive to unneces-

sary exposure to light and the reconstituted solution should be protected from light.

Use within 8 hours of reconstitution.

After reconstitution in the vial the solution may be stored, suitably protected from light, at 4°C for 72 hours or at normal room temperature for up to 8 hours.

If the reconstituted solution is further diluted in 5% Dextrose Injection BP or Sodium Chloride Injection BP 0.9% the resulting solution may be stored at 4°C for up to 24 hours.

Legal category POM.

Package quantities Vials containing 100 mg and 200 mg DTIC-Dome as sterile dacarbazine.

Further information When reconstituted each ml of solution for injection contains:

dacarbazine 10 mg, citric acid 10 mg and mannitol 5.0 mg (100 ml vial) or 3.75 mg (200 ml vial) pH 3.0–4.0.

Product licence numbers

100 mg 0055/0046

200 mg 0055/0047

MIGRAVESS*

Presentation Round, flat, white tablets, 22 mm diameter engraved with a breakline and a letter 'M' in each half of the tablet.

Each dry tablet contains:

Metoclopramide Monohydrochloride	5 mg
Aspirin BP	325 mg
Sodium Bicarbonate PhEur	1180 mg
Citric Acid PhEur	850 mg

Uses Analgesic/anti-emetic for the rapid symptomatic relief of headache and nausea associated with migraine.

Dosage and administration *Adults:* 2 tablets dissolved in water to be taken at the first symptoms of a migraine attack. If the attack persists the dose may be repeated up to a maximum of 3 doses (6 tablets) per day.

Children/young adults (10–15 years): Half the adult dose.

Migravess must be dissolved completely in half a glass of water before taking.

Contra-indications, warnings, etc True hypersensitivity to salicylates. Migravess should not be administered concomitantly with atropine, any anticholinergic drugs or concurrent with the administration of phenothiazines or butyrophenones. If vomiting persists the patient should be reassessed to exclude the possibility of an underlying disorder e.g. cerebral irritation.

Side-effects: Various extra-pyramidal reactions to metoclopramide have been reported, particularly in the young and the elderly. The incidence may be increased if daily doses in excess of those recommended are administered. The rarely occurring reactions include spasm of facial, extra ocular or cervical muscles. There may be a generalised increase in muscle tone. Any side-effects normally disappear within 24 hours of withdrawal of the drug.

Should treatment be required an anti-Parkinson drug of the anticholinergic type may be used to counteract these reactions.

In common with most anti-emetic drugs, metoclopramide may cause drowsiness but this is less common than with antihistamines.

Although studies in several mammalian species have

demonstrated no teratogenic effects with metoclopramide the use of Migravess is not recommended during the first trimester of pregnancy.

Each tablet contains 14 m Eq Na⁺.

Overdosage: Treat with gastric lavage and supportive therapy. Atropine 2 mg i.m. should be given for dystonic reactions in adults.

Pharmaceutical precautions Store at room temperature in a dry place and do not remove tablets from the foil until required.

Legal category POM.

Package quantities Migravess is available in cartons of 30 tablets (15 strips of 2 tablets). The tablets are packed in moisture proof aluminium foil laminate.

Further information Migravess presents aspirin and metoclopramide in effervescent form intended to hasten gastric emptying and therefore absorption, with freedom from the side-effects often associated with ergotamine containing preparations.

Product licence number 0055/0050.

NYSTAFORM[®]-HC OINTMENT NYSTAFORM[®]-HC CREAM

Presentation *Nystaform-HC ointment: Active ingredients:* Nystatin BP 100,000 units/g; Chlorhexidine acetate BP 1.0% w/w; Hydrocortisone PhEur 1.0% w/w.

Form and appearance: Nystaform-HC ointment is a yellow ointment containing the active ingredients in a water-repellent base.

Nystaform-HC cream: Active ingredients: Nystatin BP 100,000 units/g; Chlorhexidine hydrochloride BP 1.0% w/w; Hydrocortisone PhEur 0.5% w/w.

Form and appearance: Nystaform-HC cream is a light yellow cream containing the active ingredients in a water miscible base.

Uses *Actions:* Nystatin is a fungistatic and fungicidal antibiotic primarily effective against *Candida albicans*. Chlorhexidine has activity against a wide range of bacteria. Hydrocortisone exercises a vasoconstrictive effect, thus reducing inflammation and oedema and also has an antipruritic effect.

Indications: Nystaform-HC preparations are indicated in infected dermatoses where fungal (particularly monilial) and/or bacterial infection is present. The choice of cream or ointment presentations will depend upon the severity, physical characteristics and site of the condition, and upon the physician's preference.

Dosage and administration For topical application only. Apply liberally to infected areas 2-3 times daily. Continue application for one week after lesions have healed. This dosage is recommended for both children and adults.

Contra-indications, warnings, etc

Contra-indications: Tuberculous lesions of the skin. Known sensitivity to any of the ingredients.

Precautions: For external use only. Keep out of eyes. In infants, long term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusions. As with other topical corticosteroids, systemic absorption may occur when extensive areas are treated, particularly under occlusion.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to humans has not been established. However, topical steroids should not be used extensively in the first trimester of pregnancy, i.e. in large amounts or for prolonged periods. However, the unproven theoretical teratogenic hazard must be placed in perspective against the need to maintain the health of the patient.

Overdosage: Not applicable.

Main side-effects/adverse reactions: None reported.

Pharmaceutical precautions *Storage:* Store in a cool place.

Legal category POM.

Package quantities Nystaform-HC cream and ointment 15 g and 30 g tubes.

Further information If sensitivity occurs, or if new infection appears, discontinue use and institute appropriate therapy.

The micronisation and microdispersion of the hydrocortisone in Nystaform-HC preparations ensure that the dispersal of this active ingredient over the affected area is as uniform as possible.

The water miscible base of Nystaform-HC cream is particularly easy to apply to inflamed and tender skin. It is pleasant to use and does not leave the skin feeling greasy. The water repellent base of Nystaform-HC ointment spreads easily and helps to protect against urine when used in the nappy rash area.

NYSTAFORM[®] OINTMENT NYSTAFORM[®] CREAM

Presentation *Nystaform ointment: Active ingredients:* Nystatin BP 100,000 units/g; Chlorhexidine acetate BP 1.0% w/w.

Form and appearance: Nystaform ointment is a yellow ointment containing the active ingredients in a water-repellent base.

Nystaform cream: Active ingredients: Nystatin BP 100,000 units/g Chlorhexidine hydrochloride BP 1.0% w/w.

Form and appearance: Nystaform cream is a light yellow cream containing the active ingredients in a water miscible base.

Uses *Actions:* Nystatin is a fungistatic and fungicidal antibiotic primarily effective against *Candida albicans*. Chlorhexidine has activity against a wide range of bacteria.

Indications: For the treatment of infected skin conditions where fungal (particularly monilial) and/or bacterial infections are present.

Dosage and administration For topical application only. Apply liberally to infected area 2-3 times daily. Continue application for one week after lesions have healed.

This dosage is recommended for both children and adults.

The patient should be advised that if the condition is not better within seven days, to return to the surgery for a further consultation. In any event the duration of this treatment should not normally exceed fourteen days.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to any of the ingredients.

Precautions: For external use only. Keep out of eyes.

Overdosage: Not applicable.

Main side-effects/adverse reactions: None reported.

Pharmaceutical precautions *Storage:* Store in a cool place.

Legal category POM.

Package quantities 30 g tubes.

Further information If sensitivity occurs, or if new infection appears, discontinue use and institute appropriate therapy.

The water miscible base of Nystaform cream is particularly easy to apply to inflamed and tender skin. It is pleasant to use and does not leave the skin feeling greasy. The water repellent base of Nystaform ointment spreads easily and helps to protect against urine when used in the nappy rash area.

Greenford, Middlesex UB6 0HD

AIRBRON*

Presentation Airbron is a clear, colourless, sterile aqueous solution of 20% w/v *N*-acetylcysteine (*N*-acetyl-3-mercapto-alanine) adjusted to pH 7.0 with sodium hydroxide.

Uses Acetylcysteine, a derivative of the naturally occurring amino acid L-cysteine, is neither an enzyme nor a detergent.

Airbron dramatically reduces the viscosity and tenacity of sputum, its liquefying action being due to the presence in acetylcysteine of a free sulphhydryl group which opens up disulphide bonds present in mucus. The high viscosity of secretions in various pulmonary conditions is dependent primarily on their content of mucoprotein and, when an acute infection is involved, of deoxyribonucleic acid. The mucolytic activity of acetylcysteine is unaffected by the presence of deoxyribonucleic acid and it is, therefore, equally effective against purulent and non-purulent mucus.

Airbron facilitates the removal of mucus in broncho-pulmonary diseases:

In general medicine: Chronic bronchitis with or without emphysema, Bronchiectasis, Lung abscesses.

In anaesthetics: During general anaesthesia. Post-operative care. Pulmonary complications of heart or lung surgery. Intensive care (including routine cleansing of tracheostomies).

Dosage and administration Airbron is administered topically by nebulisation, direct instillation or, occasionally, by percutaneous intratracheal catheter. Apparatus should be of plastic or glass. Metals (particularly iron, copper and nickel) and rubber should be avoided as they react with the drug. Airbron is rapidly inactivated by high concentrations of oxygen.

By nebulisation: 1–10 ml Airbron may be given into a face mask, mouth piece, tracheostomy tube or opening every two to six hours. Usually 2–5 ml three or four times a day are sufficient for most cases.

If given into a tent, sufficient Airbron should be used to maintain a heavy mist for the duration of the treatment period and up to 250 ml may be administered.

By direct instillation: 1–2 ml Airbron may be given every one to four hours.

Contra-indications, warnings, etc Studies in various animal species have shown that acetylcysteine is virtually non-toxic and no contra-indications have been reported.

Precautions: As Airbron loosens large volumes of mucus, patients who cannot cough it up may require mechanical suction to maintain an open airway.

Care should be exercised in administering Airbron to asthmatic patients, as cases of bronchospasm have been reported. If bronchospasm occurs, Airbron should be replaced by a sympathomimetic agent, such as salbutamol, in aerosol form.

Side-effects: Side-effects due to Airbron are slight and infrequent. Stomatitis, nausea and vomiting, coughing and irritation have occasionally been reported. During nebulisation the patient may at first notice a slightly disagreeable odour, but this usually disappears. With a face mask, there may be stickiness on the face which can easily be removed by washing with warm water.

Pharmaceutical precautions Airbron should be stored in a cool place. If only a portion of a vial is used, the remainder should be stored in a refrigerator and used within 96 hours.

Legal category POM.

Package quantities Airbron is supplied in ampoules of 2 ml in containers of 25, and in multidose vials of 10 ml in containers of 3.

Further information Airbron is not suitable for use with an ordinary hand nebuliser as pressure of between 6 and 10 lbs per square inch should be used to produce a particle size of 10 microns or less.

Product licence number 0021/5026.

ANCOLOXIN* TABLETS

Presentation White tablets engraved DF/AR, each tablet containing:

Meclozine Hydrochloride BP	25 mg
Pyridoxine Hydrochloride BP	50 mg

Uses Meclozine hydrochloride is an anti-histamine of the piperazine group with marked anti-emetic properties and a duration of action of 12–24 hours. Its toxicity is low and it has been widely investigated for possible teratogenic effects in man. Pyridoxine hydrochloride (vitamin B₆) complements the action of meclozine. It forms, with other vitamins of the B group, part of an enzyme system concerned with the metabolism of amino acids. Severe vomiting is sometimes associated with a specific deficiency of pyridoxine and administration of this vitamin is of value in the treatment of such cases. Ancoloxin is indicated for the prevention and treatment of most forms of nausea and vomiting.

Dosage and administration *Radiation sickness:* 1 or 2 tablets two or three times a day.

Post-operative vomiting: 2 tablets not less than four hours before surgery.

Severe nausea and vomiting of pregnancy: 2 tablets at night; an additional tablet may be taken in the morning.

Nausea and vomiting in other conditions: 1 or 2 tablets two or three times daily, according to the severity of the symptoms.

Ancoloxin is not recommended for children.

Contra-indications, warnings, etc There are no contra-indications.

Precautions: Whilst drug therapy is undesirable during the first trimester of pregnancy the administration of Ancoloxin may be warranted if vomiting is severe.

Side-effects: Like other antihistamines, Ancoloxin occasionally gives rise to drowsiness. Patients should be advised not to drive a car or operate machinery if they feel sleepy and warned that drowsiness is more likely to occur if alcohol is taken.

Overdosage: Gastric aspiration and lavage with 1% sodium bicarbonate solution and general supportive measures.

Pharmaceutical precautions Ancoloxin Tablets should be stored in well closed containers.

Legal category POM.

Package quantities Ancoloxin Tablets are available in containers of 50 and 250.

Further information Nil.

Product licence number 0021/5060.

BETA-CARDONE*

Presentation *Beta-Cardone Tablets 200 mg:* White, circular, scored tablets engraved DF/BC20, each containing sotalol hydrochloride 200 mg.

80 mg: Red, circular, scored tablets engraved DF/BC8, each containing sotalol hydrochloride 80 mg.

40 mg: Green, circular, scored tablets engraved DF/BC4, each containing sotalol hydrochloride 40 mg.

Beta-Cardone Injection: 5 ml ampoules containing sotalol hydrochloride 10 mg in each 5 ml of solution.

Uses Beta-Cardone is a β -adrenoceptor blocking agent which is devoid of intrinsic sympathomimetic and local anaesthetic activity. Its major therapeutic effect is to protect the heart from undesirable sympathetic activity. Beta-Cardone reduces the rate and force of contraction of the heart; cardiac work and oxygen consumption are diminished.

In angina pectoris: Beta-Cardone reduces the frequency and severity of anginal attacks and increases exercise tolerance.

In hypertension: Beta-Cardone reduces blood pressure without the side-effects usually associated with peripherally acting hypotensive drugs.

In cardiac arrhythmias: Beta-Cardone is used to restore normal rate and rhythm or to reduce the rate of ventricular contraction, particularly in arrhythmias of supraventricular origin. It is also indicated for the control and prevention of arrhythmias after recent myocardial infarction.

In thyrotoxicosis: Beta-Cardone is recommended for short-term symptomatic relief of sympathetic over-activity as an adjunct to specific anti-thyroid therapy.

Dosage and administration *Oral administration in adults:*

General instructions: When administering Beta-Cardone to a patient for the first time, it is desirable to start with a low dose and gradually increase the dose until the desired response is obtained; as a general rule the heart rate should not be reduced to less than 55 beats per minute.

No special precautions, other than the observance of

the contra-indications listed below, are required when transferring patients to Beta-Cardone from other β -blockers. Beta-Cardone can be administered in conjunction with diuretic agents, digitalis, lignocaine and specific anti-thyroid drugs such as carbimazole. The following are guide lines for oral administration.

Dosage in angina pectoris: The optimum dosage is usually found to be between 200 mg and 600 mg per day in a single or divided dose.

Treatment should be initiated with 80 mg twice daily for the first 7 to 10 days. The patient may then be given 200 mg once daily, preferably on rising in the morning. Further increments of 200 mg may thereafter be given, if necessary, at intervals of two or more weeks but, in angina pectoris, it is rarely found necessary to administer more than 400 mg per day.

Dosage in hypertension: The optimum dosage is usually found to be between 200 mg and 600 mg per day in a single or divided dose.

Again treatment should be initiated with 80 mg twice daily for the first 7 to 10 days. The patient may then be given 200 mg once daily, preferably on rising in the morning. Further increments of 200 mg may thereafter be given, if necessary, at intervals of two or more weeks and, in hypertension, there have been occasional reports of up to 4,000 mg being administered daily in divided doses.

Dosage in cardiac arrhythmia: The optimum dosage is usually found to be between 120 mg and 240 mg per day in a single or divided dose.

Dosage in Thyrotoxicosis: In most cases it has been found that a dosage of between 120 mg and 240 mg per day, in a single or divided dose, will reduce sympathetic overactivity.

In cardiac arrhythmia and thyrotoxicosis, treatment should be commenced with a dose of 40 mg, three times daily for the first 7 to 10 days. Once the maintenance phase is reached a single dose of 200 mg daily, preferably on rising in the morning, may be adequate.

Intravenous administration in adults:

Dosage in acute cardiac arrhythmias: In acute cardiac arrhythmias, especially those following myocardial infarction, 10–20mg of Beta-Cardone (i.e. 5–10 ml of Beta-Cardone injection) should be given slowly by the intravenous route; similar doses may be repeated if required.

Contra-indications, warnings, etc

Heart block and bronchospasm: Beta-Cardone should not be given to patients suffering from heart block or who have a history of bronchospasm.

In patients with poor cardiac reserve β -blockade can precipitate heart failure; in such cases, Beta-Cardone therapy should not be commenced until the patient has been controlled by cardiac glycosides and, if necessary, diuretic therapy.

Warning: There have been reports of skin rashes and/or dry eyes associated with the use of β -adrenoceptor-blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when the treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a β -blocker should be gradual.

Diabetic keto-acidosis and metabolic acidosis: Beta-Cardone should not be given to patients suffering from diabetic keto-acidosis or metabolic acidosis; therapy

with Beta-Cardone can be commenced or resumed when the metabolic condition has been corrected.

Treated diabetes: Beta-Cardone, like other β -blocking agents, may reduce or mask the usual pre-hypoglycaemic warning signs.

General anaesthesia: If desired, Beta-Cardone may be stopped four days prior to surgery. However, where sudden withdrawal might expose the patient to severe angina or arrhythmias, anaesthesia can proceed provided that the following precautions are taken.

1. Vagal dominance is counteracted by premedication with atropine sulphate (0.25–2.0 mg) administered intravenously.

2. Ether, chloroform, cyclopropane and trichlorethylene are not used.

Pregnancy: Animal studies with sotalol hydrochloride have shown no evidence of teratogenicity or other harmful effects to the fetus, nevertheless its use throughout pregnancy should be avoided unless it is absolutely necessary. It crosses the placenta and may cause fetal bradycardia.

Breast milk: Infants should not be fed with breast milk from mothers being treated with Beta-Cardone.

Alcoholism: Beta-adrenoceptor blocking drugs may precipitate cardiac failure in alcoholic patients.

Renal insufficiency: Since Beta-Cardone is mainly excreted unchanged in the urine, accumulation may be avoided by reduction in dosage.

Upper respiratory infections: In these conditions patients without a history of airways obstruction may suffer bronchospasm from β -blockade.

Side-effects: Beta-Cardone is usually well tolerated. Bronchoconstriction has been reported in a few sensitive individuals; it may be controlled by the intravenous administration of atropine sulphate (0.25–2.0 mg) and/or by inhalation of a selective β -adrenoceptor stimulant such as salbutamol.

Interactions: In combined therapy clonidine should not be discontinued until several days after withdrawal of Beta-Cardone.

Overdosage: Overdosage causes excessive bradycardia and hypotension; to counteract this atropine sulphate (0.25–2.0 mg) should be administered intravenously and, if need be, isoprenaline (about 5 mcg per minute) by slow intravenous injection.

Pharmaceutical precautions Beta-Cardone Tablets and Injection should be protected from light.

Legal category POM.

Package quantities Beta-Cardone Tablets 200 mg are available in containers of 30 tablets.

Beta-Cardone Tablets 80 mg are available in containers of 100 and 500 tablets.

Beta-Cardone Tablets 40 mg are available in containers of 100 and 500 tablets.

Beta-Cardone Injection is available in ampoules of 5 ml in boxes of 10 ampoules.

Further information Beta-Cardone is not metabolised and, in the main, is excreted in the urine. After oral administration the plasma half life has been shown to be 17 hours; the lipid solubility is very low.

DF 118

Presentation DF 118 Tablets: White tablets engraved DF 118. Each tablet contains Dihydrocodeine Tartrate BP 30 mg.

Elixir DF 118: A brown syrup. Each 5 ml contains Dihydrocodeine Tartrate BP 10 mg.

DF 118 Injection: A colourless solution. Each ampoule contains in 1 ml Dihydrocodeine Tartrate BP 50 mg.

Uses Relief of moderate to severe pain. The action of dihydrocodeine tartrate is almost purely analgesic – it is virtually free from sedative or hypnotic effects. 30 mg given parenterally has been shown to have an analgesic potency equivalent to that of 10 mg of morphine; in a study of oral analgesics for the relief of chronic pain, the same dose was found to be equivalent to 100 mg of pethidine. In both these trials dihydrocodeine was found to have a lower incidence of side-effects than either morphine or pethidine.

It is fully active when administered orally and, in the recommended doses, causes little or no respiratory depression; in addition to being a potent analgesic the compound also exhibits well-defined antitussive activity.

DF 118 is indicated in all painful conditions where an alert patient is desired, viz. sciatica, osteoarthritis, chronic rheumatoid arthritis, arthritis of the spine, peripheral vascular disease, post-herpetic neuralgia, Paget's disease, malignant disease, post-operative pain.

Because DF 118, in the recommended doses, causes little or no respiratory depression, its use in the treatment of post-operative pain may reduce the risk of chest complications.

Dosage and administration *General information:* As DF 118 is fully active when administered orally this route is to be preferred whenever possible. The analgesic effect of DF 118 is not materially enhanced by increasing the dose above that recommended below; in severe cases the interval between doses should be reduced to obtain the requisite analgesic cover.

DF 118 is best administered with or after food. It is not recommended for administration to children under 4 years.

Elixir DF 118 is a pleasant tasting liquid suitable for administration to patients who may have difficulty swallowing the tablets.

Dosage – Analgesia.

Adults: DF 118 Tablets: 1 tablet (30 mg) every four to six hours or at the discretion of the physician.

Elixir DF 118: One to three 5 ml spoonfuls (10–30 mg) every four to six hours or at the discretion of the physician.

DF 118 Injection: Patients who, for one reason or another are unable to be treated with the tablets or elixir may be given up to 50 mg by intramuscular or deep subcutaneous injection.

Children aged 4 to 12 years: 0.5 to 1 mg/kg body weight every 4 to 6 hours.

Dosage – Antitussive.

Adults: Elixir DF 118: One 5 ml spoonful (10 mg) every four to six hours or at the discretion of the physician.

Children aged 4 to 12 years: 200 mcg/kg body weight every 4 to 6 hours.

Contra-indications, warnings, etc Respiratory depression; obstructive airways disease.

Precautions: As dihydrocodeine may bring about histamine-release, DF 118 should not be given during an attack of asthma and it should be administered with due care to persons liable to such attacks.

Dosage should be reduced in the elderly, in hypothyroidism and in chronic hepatic disease. Alcohol should be avoided whilst under treatment with DF 118.

There is no, or inadequate evidence of safety in human pregnancy but the drug has been used for many years without apparent ill consequence.

Side-effects: Constipation, nausea, vomiting, headache and vertigo occur and are relatively more common when the dose is increased above 30 mg. If constipation occurs it can be treated with a gentle laxative.

Overdosage: Conservative management is recommended; gastric lavage should be carried out. Severe respiratory depression can be treated with naloxone hydrochloride 0.4 mg subcutaneously, repeated as required at 2 or 3 minute intervals.

Pharmaceutical precautions The recommended diluent of the Elixir is Unpreserved Syrup BP, or syrup preserved with *p*-hydroxybenzoic acid. The resulting dilution will keep for 14 days at room temperature.

DF 118 preparations should be protected from light.

Legal category DF 118 Tablets POM.

Elixir DF 118 POM.

DF 118 Injection POM: MDA.

Package quantities DF 118 Tablets are available in packs of 100 and 500.

Elixir DF 118 is available in bottles of 150 ml and 1 litre.

DF 118 Injection is available in boxes of 5 ampoules of 1.1 ml.

Further information In patients already habituated to a drug such as pethidine, the substitution of dihydrocodeine in equi-analgesic doses has led to the appearance of abstinence symptoms. This suggests that dihydrocodeine, despite its effectiveness as an analgesic, has a very low addiction potential and can be safely administered more frequently than the more potent narcotic drugs and for longer periods.

Elixir DF 118 0021/0053R

DF 118 Injection 0021/5028R

DINDEVAN* TABLETS

Presentation *Dindevan Tablets 10 mg:* White tablets engraved DF/D10, each tablet containing Phenindione BP 10 mg.

Dindevan Tablets 25 mg: Green tablets engraved DF/D25, each tablet containing Phenindione BP 25 mg.

Dindevan Tablets 50 mg: White tablets engraved DF/D50, each tablet containing Phenindione BP 50 mg.

Uses Dindevan (Phenindione BP) is a synthetic anticoagulant which acts by interfering with the formation of certain clotting factors. It produces its effect in 36–48 hours after the initial dose; the effect wanes over a period of 48–72 hours after Dindevan is stopped.

Coronary occlusion; deep vein thrombosis; pulmonary embolism; peripheral vascular thromboembolic states;

mesenteric and retinal thromboembolism. In emergencies, such as the conditions listed above, anticoagulant therapy should be initiated with heparin and Dindevan together. Where there is less urgency, as in patients at special risk of thromboembolism, anticoagulant therapy may be initiated with Dindevan alone.

Appropriate indications include predisposition to thromboembolism following surgery, during pregnancy and the puerperium, and chronic embolic pulmonary hypertensive disease.

Dosage and administration *Initial loading dose:* Usually 200 mg, followed on the second day with a dose of 100 mg.

Maintenance therapy: Dosage must be adjusted, from the third day, in accordance with the results of appropriate coagulation tests. Concomitant heparin therapy affects the results of control tests and should be discontinued at least six hours before the first test is carried out.

Control tests must be made at regular intervals and the dosage further adjusted according to the results obtained. As a general guide, a maintenance dosage of between 50–150 mg per day will prove satisfactory in most cases. Occasionally, a resistant patient may need 200 mg or more per day; on the other hand a sensitive patient may need less than 50 mg per day.

Contra-indications, warnings, etc

Contra-indications: Dindevan should not be given in the presence of severe hepatic or renal disease, actual or potential haemorrhagic conditions, or to patients with uncontrolled hypertension. Its use within 24 hours following surgery or labour should be undertaken with caution, if at all.

Precautions: The following factors may exaggerate the effects of Dindevan and necessitate a reduction in dosage; loss of weight; elderly subject; acute illness; deficient renal function; decreased dietary intake of vitamin K; administration of a number of drugs, including salicylates, quinidine, broad-spectrum antibiotics, phenformin, tolbutamide, phenylbutazone, indomethacin, cimetidine, azapropazone, clofibrate, ACTH and corticosteroids and all potentially hepato-toxic drugs.

Factors which may call for an increase in maintenance dosage include weight gain, gastro-intestinal upset, increased intake of vitamin K, fats and oils, and administration of drugs (e.g. phenobarbitone) that increase liver enzyme activity.

Oral anticoagulants should not be used in pregnancy unless there are firm indications. In particular, because of possible teratogenicity, they should not be used for the remainder of the first trimester following diagnosis. In addition the risk of foetal haemorrhage is increased when they are used near term. It is therefore suggested that heparin (which does not cross the placenta) be used during the first trimester and after 37 weeks' gestation. However, the use of heparin in pregnancy is not absolutely safe and specialist guidance is advisable for those who are pregnant and who need anti-coagulant therapy. Women of child-bearing age who are receiving treatment with Dindevan should be cautioned about the possible complications of pregnancy. Infants should not be fed with breast milk from mothers being treated with Dindevan.

Side-effects: The following effects have been reported: skin rashes of various kinds, skin necrosis, fever, leucopenia and agranulocytosis, diarrhoea, hepatitis and renal damage with tubular necrosis. If any of these are

observed administration of Dindevan should stop immediately and full investigations of blood and of liver and kidney function should be carried out. Possible sensitivity to other drugs should be considered. Other anticoagulants, such as Marevan[®], are usually tolerated by patients sensitive to Dindevan. If therapy is controlled as recommended then bleeding due to overdosage of anticoagulant is rare. An episode of bleeding occurring during anticoagulant therapy must, therefore, be investigated fully and not regarded automatically as a manifestation of overdosage.

N.B. The metabolites of Dindevan often colour the urine pink or orange. This may be distinguished from discoloration caused by haemoglobin by the addition of a few drops of dilute acetic acid to the urine. If the colour is due to Dindevan it will disappear immediately.

Overdosage: If haemorrhage occurs or a potential bleeding state arises, excessive depression of the coagulation activity can be corrected by temporary withdrawal of Dindevan accompanied, if necessary, by administration of vitamin K₁, in oral doses of 2–20 mg; rarely it may be necessary to give vitamin K₁ intravenously, or to infuse fresh whole blood.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Dindevan Tablets 10 mg. Dindevan Tablets 25 mg and Dindevan Tablets 50 mg are each available in containers of 100 and 500 tablets.

Further information Nil.

ADSORBED DIPHTHERIA AND TETANUS VACCINE BP (PTAH) (DT/Vac/Ads)

Presentation Adsorbed Diphtheria and Tetanus Vaccine is a mixture of diphtheria formol toxoid and tetanus formol toxoid adsorbed on aluminium hydroxide; each 0.5 ml dose contains not less than 30 i.u. of diphtheria toxoid and not less than 40 i.u. of tetanus toxoid.

Uses Active immunisation against diphtheria and tetanus in infants and children. Reinforcement of immunity to diphtheria and tetanus in children under the age of 10 years.

Dosage and administration *Children under 10 years:* Adsorbed Diphtheria and Tetanus Vaccine (0.5 ml) should be administered by intramuscular injection; the container should be shaken before withdrawing the prescribed dose.

Basic course: The course consists of three doses with an interval of 6–8 weeks between the first and second dose and 4–6 months between the second and third dose.

Reinforcing doses: Children under the age of 10 years immunised in infancy with diphtheria and tetanus adsorbed vaccine or diphtheria, tetanus and pertussis vaccine should receive a reinforcing dose of diphtheria and tetanus vaccine at 5 years of age.

Contra-indications, warnings, etc

Contra-indications: Presence of acute infectious disease.

Warnings: A sterile syringe and Adrenaline Injection BP should be ready for use in case the need arises for emergency treatment of an allergic reaction.

Not for intradermal use.

Adverse effects: Acute allergic reactions, pallor and dyspnoea are rarely reported. Transient pyrexia, headaches, malaise, local swelling, redness and tenderness may occur. A small painless nodule may form at the injection site.

Pharmaceutical precautions Protect from light. Store between 2°C and 8°C (36°F and 46°F). Do not freeze.

Partly used multidose containers should be discarded within three hours of withdrawal of the first dose.

Legal category POM.

Package quantities Single-dose ampoules containing 0.5 ml and multidose vials containing 5 ml.

Further information Nil.

Product licence number 0021/0061.

ADSORBED DIPHTHERIA, TETANUS AND PERTUSSIS VACCINE BP (PTAH) (DTPer/Vac/Ads)

Presentation Adsorbed Diphtheria, Tetanus and Pertussis Vaccine is a mixture of diphtheria formol toxoid, tetanus formol toxoid and killed *Bordetella pertussis* organisms.

Each 0.5 ml dose contains not less than 30 i.u. diphtheria toxoid, 60 i.u. tetanus toxoid (estimated by mouse test) and 4 i.u. *B. pertussis* adsorbed on aluminium hydroxide; the pertussis component contains the currently known immunogenic serotypes of *B. pertussis*.

Uses Active immunisation against diphtheria, tetanus and whooping cough in children under the age of five years.

Dosage and administration Adsorbed Diphtheria, Tetanus and Pertussis Vaccine should be administered by intramuscular injection. The container should be shaken before withdrawing the prescribed dose.

The routine course of immunisation consists of 3 doses, each of 0.5 ml, beginning after the age of three months. The Department of Health and Social Security recommends the first dose should preferably be given at three months of age, the second after an interval of six to eight weeks and the third four to six months later.

In the event of a whooping cough epidemic three doses may be given at monthly intervals, starting at the age of three months. In this case a booster dose of DT/Vac/Ads should be given between the ages of 12 and 18 months.

Contra-indications, warnings, etc

Contra-indications: Adsorbed Diphtheria, Tetanus and Pertussis Vaccine should **not** be given to adults or children over the age of three years.

It is advisable to postpone vaccination if the child is suffering from any acute febrile illness, particularly respiratory, until fully recovered. (Minor infections without fever or systemic upset are not regarded as a contra-indication.)

Vaccination should not be carried out in children who have:

- (a) a history of any severe local or general reaction (including a neurological reaction) to a preceding dose;
- (b) a history of cerebral irritation or damage in the neonatal period, or who have suffered from fits or convulsions.

Even when pertussis vaccine is contra-indicated an infant should still be considered for immunisation against diphtheria and tetanus.

Precautions: There are certain groups of children in whom whooping cough vaccination is not absolutely contra-indicated but who require special consideration as to its advisability. These groups are:

- (a) children whose parents or siblings have a history of idiopathic epilepsy;
- (b) children with developmental delay thought to be due to a neurological defect;
- (c) children with neurological disease.

For these groups the risk of vaccination may be higher than in normal children but the effects of whooping cough may be more severe, so that the benefits of vaccination would also be greater. The balance of risk and benefit should be assessed with special care in each individual case.

A personal or family history of allergy has in the past been regarded as a contra-indication to vaccination but there is now a substantial body of medical opinion which no longer considers this to be so. Doctors should, however, use their own discretion in the individual case.

Side-effects: Local oedema and redness sometimes occur, particularly if the vaccine has been administered by subcutaneous rather than intramuscular injection; superficial injections may also give rise to a local nodule at the site of injection.

Encephalitis has been reported after the administration of Pertussis Vaccine with incidence variously reported between 1 in 1,000 to 1 in 10,000 cases.

Warnings: A sterile syringe and Adrenaline Injection BP should be ready for use, in case the need arises for emergency treatment of an allergic reaction.

Not for intradermal use.

Pharmaceutical precautions Protect from light. Store in a refrigerator between 2°C and 8°C (36°F and 46°F). Do not freeze.

Partly used multi-dose containers should be discarded within three hours of withdrawal of the first dose.

Legal category POM.

Package quantities Single-dose ampoules containing 0.5 ml and multidose vials containing 5 ml.

Further information Nil.

Product licence number 0021/0062.

EXTIL* COMPOUND LINCTUS

Presentation A reddish-pink, translucent linctus, each 10 ml dose containing:

Noscapine BP	25 mg
Pseudoephedrine (equivalent to 60 mg Pseudoephedrine Hydrochloride BPC)	49.2 mg
Carbinoxamine maleate	6 mg

Uses The antitussive activity of noscapine, an isoquinoline derivative, is comparable to that of codeine. Unlike codeine, noscapine has no narcotic or analgesic

effect, does not depress the respiratory centre and, in normal dosage, does not cause constipation.

Pseudoephedrine has decongestant and bronchodilator properties similar to those of ephedrine, but is relatively less toxic and less active as a cardiac and CNS stimulant.

The antihistamine, carbinoxamine maleate, complements the effect of pseudoephedrine and is valuable in conditions where an allergic component is present.

Extil Compound Linctus is indicated in troublesome cough, especially cough accompanied by bronchospasm or congestion of the upper respiratory tract. Also in cough associated with the common cold; in such conditions it not only relieves the cough but reduces both nasal and bronchial congestion.

Dosage and administration *Adults and children over 12:* One 10 ml dose three or four times a day as required.

Children over 2 years and up to 12: Half to one 5 ml dose three or four times a day as required.

Contra-indications, warnings, etc

Contra-indications: Should not be given to patients suffering from advanced hypertension or heart failure, or undergoing treatment with monoamine oxidase inhibitors.

Precautions: Carbinoxamine only rarely gives rise to drowsiness, but as alcohol potentiates the action of antihistamines, patients should be warned that drowsiness may well occur if alcohol is taken.

Notice should be taken of current views that any drug should be prescribed with caution during pregnancy.

Side-effects: Pseudoephedrine in clinical doses has very little pressor activity in normotensive individuals, but minor side-effects, similar to those encountered with ephedrine, may occur if the recommended dosage is exceeded.

Overdosage: Gastric lavage and general supportive measures.

Pharmaceutical precautions Extil Compound Linctus must not be shaken or diluted.

Legal category POM.

Package quantities Extil Compound Linctus is available in bottles of 500 ml.

Further information Noscapine does not produce addiction: It has been recommended by the World Health Organisation as a substitute for codeine for suppression of cough.

Product licence number 0021/5004.

FAZADON*

Presentation A clear yellow solution containing fazadinium bromide equivalent to 15 mg of fazadinium per ml. Each 5 ml ampoule contains the equivalent of 75 mg of fazadinium base made isotonic by the inclusion of 0.6% w/v of sodium chloride and stabilised with 0.3% w/v of α -thioglycerol – the latter gives the solution a characteristic smell of sulphides.

Uses Fazadon is a neuromuscular blocking agent for *intravenous administration*; it acts by competitive (non-depolarising) blockade of the acetylcholine receptors in the motor-end plates.

Fazadon produces profound muscular relaxation within 60 seconds and, at the recommended dosage,

this profound relaxation is maintained for about 40 minutes. It is indicated in surgical and obstetric procedures which call for endotracheal intubation and subsequent muscle relaxation.

Its action is reversed promptly and permanently by the administration of an anticholinesterase drug.

Dosage and administration For adults, the dose, given intravenously, should be calculated on the basis of 0.75 mg to 1 mg per kilogram body weight. At this dosage sufficient laryngeal relaxation for intubation may be expected in between 30 and 60 seconds.

At present there is insufficient evidence to recommend a dosage regimen for routine use in children under 10 years of age.

Increments: Increments of up to 1 ml according to body weight and clinical circumstances (i.e. approximately 25% of the initial dose) should provide relaxation for a further period of between 10 to 20 minutes.

Reversal: The action of Fazadon is completely and permanently reversed by 2.5 to 5 mg of neostigmine methylsulphate administered intravenously; the bradycardia following the intravenous administration of neostigmine may be avoided by the prior intravenous administration of 1.0 mg atropine sulphate.

Contra-indications, warnings, etc Whenever Fazadon is used, respiration must be assisted and facilities must be available for controlled ventilation.

Fazadon is a competitive inhibitor of neuromuscular transmission; it should NOT be used simultaneously with a depolarising agent.

The following anaesthetics increase the neuromuscular blocking effect of Fazadon: ether, halothane, cyclopropane, Althesin*. The following drugs may also prolong the duration of action: diazepam, pentobarbitone, clindamycin, colistin, kanamycin, neomycin, polymyxins, streptomycin, tobramycin, framycetin, amikacin, gentamicin and other amino-glycoside antibiotics.

Fazadon, with a pH of 3.2 to 4.3, must not be mixed in the same syringe with alkaline anaesthetic agents, e.g. thiopentone. Fazadon may potentiate halothane-induced hypotension.

Fazadon is mainly excreted unchanged in the urine; care should therefore be taken in patients with renal insufficiency and dosage should be reduced according to the severity of the condition.

In patients with myasthenia gravis or myasthenic syndrome Fazadon should be administered in very small doses and with extreme caution; a reduction in dosage is also advisable in cases of gross obesity, myopathy or after poliomyelitis.

It should be noted that in operations requiring hypothermia the neuromuscular blockade of non-depolarising drugs is decreased, but increases again when the patient's body temperature returns to normal.

Although animal studies have not shown any teratogenic or other harmful effects on the fetus the use of Fazadon in the first trimester of pregnancy should be avoided unless absolutely necessary.

Side-effects: A transient, moderate tachycardia often accompanies the use of Fazadon. In most patients it serves to counter an adverse effect of anaesthesia and in a few it may be more marked.

In a few cases minor local inflammatory reactions have been noticed at the site of injection.

Neither bronchospasm nor increased whole blood histamine has been reported.

Overdosage: In case of accidental overdosage the patient should remain on assisted respiration and oxygen, and should be given atropine sulphate 1 mg intravenously, followed by an adequate intravenous dose of neostigmine methylsulphate (2.5 mg to 5 mg).

Pharmaceutical precautions Store, protected from light, at a temperature not exceeding 20°C. Stored under these conditions, Fazadon is stable for two years.

Legal category POM.

Package quantities 5 ml ampoules, in boxes of 10.

Further information Fazadon crosses the placental barrier only in very small amounts, and has been shown to have no adverse effect on fetal movement; it has been used successfully in Caesarean section.

After the administration of Fazadon there is no significant change in plasma potassium or whole blood histamine levels.

Fazadon does not raise intragastric or intraocular pressure.

Product licence number 0021/0064.

FLUVIRIN* ▼

Presentation Fluvirin is Inactivated Influenza Vaccine (Surface Antigen) BP containing highly purified haemagglutinin and neuraminidase antigens prepared from those strains of influenza virus currently recommended.

Uses *Protection against influenza* especially in those cases deemed to be at special risk, viz.

Chronic pulmonary disease, e.g. chronic bronchitis and emphysema, asthma, bronchiectasis, pulmonary tuberculosis and fibrosis.

Chronic heart disease, e.g. valvular and hypertensive heart disease.

Chronic renal disease, e.g. chronic nephritis; patients with renal disease on immunosuppressive drugs.

Diabetes and possibly other less common endocrine disorders.

Patients who are being actively considered for immunosuppressive therapy.

Immunisation against influenza is also recommended in:

School children over four years of age and in elderly persons living in residential establishments, in which rapid spread is likely to follow the introduction of infection.

Doctors, nurses, ambulance men, and others at special risk of infection by reason of their contacts with persons suffering from influenza.

Dosage and administration *Adults and children over 13 years:* Single dose of 0.5 ml by deep subcutaneous or intramuscular injection.

Children aged 4 to 13 years: 2 doses of 0.5 ml, one month apart.

If the vaccine has been stored in a refrigerator it must be allowed to reach room temperature before use: the container should be well shaken immediately before making the injection. Unused contents of multidose vials should be discarded within three hours of first use.

Contra-indications, warnings, etc

Contra-indications: Fluvirin is contra-indicated in persons sensitive to egg, chicken or influenzal viral protein. Immunisation should be delayed if there is active or suspected infection.

Warnings: Because the vaccine contains highly purified haemagglutinin and neuraminidase antigens the total viral content of the vaccine has been reduced to about one tenth of that of whole virus vaccines. Even so, a sterile syringe and Adrenaline Injection BP should be ready for use, in case the need arises for emergency treatment of an allergic reaction.

Spirit should not be allowed to come in contact with the vaccine.

Side-effects: Local effects such as redness and soreness at the site of injection may occur.

Systemic effects, such as headache, pyrexia and a feeling of malaise may occur.

Both local and systemic side effects are less frequent with Fluvirin than with Inactivated Influenza Vaccine BP.

Overdosage: Not applicable.

Pharmaceutical precautions Fluvirin should be protected from light and stored at between 2°C and 8°C (36°F and 46°F). Do not freeze. Though limited exposure to light and higher temperatures has no adverse effect on the vaccine, temperatures above 20°C (68°F) should be avoided.

Legal category POM.

Package quantities Fluvirin is available in 0.5 ml disposable syringe packs, in 5 ml multidose vials and 25 ml multidose vials for hospital or industrial use with the Port-O-Jet or other suitable jet injector.

Further information Studies with surface antigen influenza vaccine have shown that the purified haemagglutinin and neuraminidase antigens contained in a single dose of Fluvirin will produce a protective antibody response in up to 90% of patients.

Product licence number 0021/0096.

JEXIN*

Presentation Jexin is Tubocurarine Injection BP and is a clear colourless, or faintly colourless sterile solution containing Tubocurarine Chloride BP 10 mg per ml.

Uses Jexin produces paralysis of voluntary muscle by interfering with transmission across the neuromuscular junction. It acts by competitive blockade of motor endplates. Paralysis appears in the muscles of the face and neck, of the limbs and of the abdomen, in that order, the intercostal muscles and diaphragm being affected last. The paralysis reaches its maximum two to five minutes after intravenous injection and lasts for about 30 minutes. There is, however, a residual action lasting for as long as 24 hours, and during this time smaller doses are required to reproduce the effect of the initial dose.

Jexin is mainly indicated as an adjunct to anaesthesia to secure muscular relaxation in surgery and obstetrics. It can also be used in tetanus.

Dosage and administration *Adults:* Dosage should be based on the response to an initial intravenous injection of 10–15 mg. A test dose of 5 mg in the unanaesthetised patient may be administered before

giving the full initial dose. Supplementary doses of 5 mg are adequate, if required for lengthy operations. A total of 40 mg for a single operation should not be exceeded.

Children: The initial dose is of the order of 0.32 mg per kg of body weight.

Contra-indications, warnings, etc

Contra-indications: Jexin is contra-indicated in patients with respiratory insufficiency or in the presence of renal or hepatic impairment.

Precautions: In patients with myasthenia gravis or myasthenic syndrome, Jexin should be administered in very small doses and with extreme caution; a reduction in dosage is also advisable in cases of gross obesity, myopathy and after poliomyelitis. Patients with asthma or those susceptible to bronchospasm require especial care as Jexin is known to cause the release of histamine. In such patients the prophylactic administration of an anti-histamine may be advisable.

Care is necessary if Jexin has to be given to a patient on two occasions within 24 hours. Administration of Jexin either with or before a depolarising relaxant, such as suxamethonium, may cause a muscle relaxation which is irreversible by neostigmine. The effects of Jexin are enhanced by ether; the hypotension produced by halothane anaesthesia is increased by Jexin and a reduced dose of Jexin should be used.

Jexin may be potentiated by diazepam and by clindamycin, colistin, kanamycin, neomycin, polymyxins, streptomycin, tobramycin, framycetin, amikacin, gentamicin and other amino-glycoside antibiotics and by quindine.

Side-effects: The dosage recommended produces few side-effects; a transient fall in blood pressure may sometimes occur.

Overdosage: Intravenous neostigmine with atropine sulphate. Oxygen and assisted respiration may be required.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Jexin is supplied in 1.5 ml ampoules in boxes of 5.

Further information Although Jexin should not normally be mixed with thiopentone, this can be done if prepared immediately prior to injection and used only if the solution remains perfectly clear.

Product licence number 0021/5025.

LOCAN* CREAM

Presentation Locan Cream, a smooth, white cream, contains:

Amylocaine	1%
Amethocaine	0.8%
Cinchocaine BPC	0.4%

in a non-greasy base which does not soil or stain the clothing.

Uses The combination of the lipid-soluble free bases of amethocaine, amylocaine and cinchocaine provides rapid, yet sustained, relief from pruritic and painful conditions.

Locan Cream is of particular value in the treatment of pruritus ani, pruritus vulvae, external haemorrhoids and anal fissure; it should also be found useful in relieving the pain of cracked or sore nipples, minor burns,

chilblains and athlete's foot. The analgesic effect may also be found useful in alleviating localised muscular pain arising from conditions which do not need prolonged treatment.

Administration A thin layer of Locan Cream should be applied over the affected area and massaged in gently until absorption is complete. The application may be renewed as required.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to local anaesthetics.

Precautions: Sensitisation may occur to the local anaesthetics contained in Locan Cream. This should be suspected, and application stopped, if increased irritation or reddening occurs.

Side-effects: No other side-effects are likely to be encountered.

Overdosage: Not applicable.

Pharmaceutical precautions No special requirements or precautions.

Legal category P.

Package quantities Locan Cream is available in tubes of 30 g.

Further information Nil.

Product licence number 0021/5010.

MARCAIN* PLAIN

Presentation Marcain Plain is Bupivacaine Hydrochloride Injection BP and is a clear, colourless, aqueous sterile solution in three strengths:

Marcain Plain 0.25%, containing Bupivacaine Hydrochloride BP 0.25% w/v.

Marcain Plain 0.5%, containing Bupivacaine Hydrochloride BP 0.5% w/v.

Marcain Plain 0.75% containing Bupivacaine Hydrochloride BP 0.75% w/v.

Uses The principal action of Marcain is to inhibit impulse transmission in nerve fibres with which it comes in contact. In a mixed nerve, sensory fibres are blocked before motor fibres; and among the different types of sensory fibres, those carrying the sensation of pain are affected before those carrying sensations of cold, heat, touch and deep pressure.

The local analgesic effect of Marcain is similar in rate of onset and depth to that of lignocaine and mepivacaine, but is of much greater duration; clinical evidence indicates that the quality of sensory blockade and interference with motor function provided by Marcain compares favourably with alternative agents. Marcain is approximately four times as potent as lignocaine or mepivacaine; hence a 0.5% solution of Marcain is equivalent in nerve-blocking activity to a 2% solution of lignocaine. Marcain is indicated primarily for specialist use in situations where prolonged analgesia is required. A list of suggested indications and the dose of solution appropriate for each are shown in the adjacent table.

Dosage and administration In nerve blocks the maximum recommended dose of Marcain in any four-hour period is 2 mg/kg, representing 25 to 30 ml of 0.5% Marcain for an adult weighing 65 to 70 kg.

In intravenous regional analgesia the method of use is to place a tourniquet cuff over padding on the upper arm. A number 21 or 23 gauge indwelling needle is placed in a suitable vein, preferably on the dorsum of the hand,

Marcain Plain				
Surgical procedure	Concentration (%)	Dose		
		(ml)	(mg)	
Brachial plexus (axillary) block	0.25	20-40	50-100	
	0.5	15-30	75-150	
Lumbar extradural block	0.25	15-20	37.5-50	
	0.5	15-20	75-100	
	0.75	10-18	75-135	
Caudal extradural block	0.25	15-40	37.5-100	
	0.5	15-25	75-125	
Continuous extradural analgesia	0.25	The dose depends on the number of segments to be rendered analgesic and the patient's age (1-3 ml per segment)		
	0.5			
	0.75			
Intercostal block	0.25	4-8	10-20	
	0.5	3-5	15-25	
Digital block (each digit)	0.25	2-10	5-25	
	0.5	2-6	10-30	
Stellate ganglion block	0.25	10-20	25-50	
Lumbar sympathetic block	0.25	10-20	25-50	
Intravenous regional analgesia	0.5	0.3 ml/kg	1.5 mg/kg	(suitably diluted - see dosage section)
	OR: 0.25	0.6 ml/kg	1.5 mg/kg	(undiluted - see dosage section)
Herniorrhaphy	0.25	30-60	75-150	
Obstetrical procedure				
Lumbar extradural block	1st stage	0.25	6-15	15-37.5 depending on site of catheter tip
	2nd stage	0.25	12-20	30-50
		0.5	8-14	40-70
Caudal extradural block	1st stage	0.25	15-30	37.5-75
	2nd stage	0.25	15-30	37.5-75
(intermittent)		0.5	10-20	50-100
Bilateral pudendal block		0.25	50-60	125-150

and the limb is exsanguinated either by simple gravity drainage or by the use of Esmarch's bandage. The cuff is then inflated to 50 mm Hg above the patient's systolic blood pressure and the injection of diluted Marcain (i.e. 0.2%) is made through the indwelling needle.

For intravenous regional analgesia Marcain Plain 0.5% may be used in a dose of 0.3 ml/kg body weight (1.5 mg/kg). The 0.5% solution should be mixed with an appropriate volume of Sodium Chloride Injection BP to reduce the concentration to 0.2% before administration by intravenous injection to the cuffed patient. Each 10 ml of 0.5% Marcain Plain will require 15 ml of Sodium Chloride Injection BP to achieve the recommended reduction in concentration to 0.2%.

Alternatively, Marcain Plain 0.25% may be used undiluted in the cuffed patient in a dose of 0.6 ml/kg body weight (1.5 mg/kg).

Satisfactory analgesia and muscle relaxation may be expected to follow in about four minutes. Following the

surgical procedure, the cuff is deflated (without subsequent reinflation) and recovery to normal sensation and tone may be expected in about eight minutes.

For herniorrhaphy Marcain 0.25% with adrenaline 1 in 400,000 is used. Usually 30 to 40 ml is sufficient for the operation; up to 60 ml may be used but the dosage should not exceed 2 mg/kg. Some operators prefer to use Marcain Plain as this aids identification of the bleeding points.

In epidural analgesia for surgical purposes, Marcain Plain 0.75% is recommended because of the increased depth of motor block obtained with this concentration.

Contra-indications, warnings, etc Known hypersensitivity.

Precautions: As with all local analgesic solutions, every care should be taken to avoid accidental intravascular injection.

Marcain Plain can be administered intravenously under controlled conditions (i.e. in the cuffed patient) as described under intravenous regional analgesia in the section 'Dosage and administration'. Care should be taken to ensure that the cuff used does not leak.

Side-effects: Hypotension after extradural or autonomic block may occur commensurate with such procedures. Other side-effects include tremor, tachycardia, bradycardia, malaise, vomiting and, rarely, convulsions or coma.

Overdosage: The occurrence of adverse effects is related directly to the concentration of the drug in the blood, which in turn depends on the dose and the site of administration. Supportive measures to maintain vital functions such as maintenance of the airway, oxygenation with or without assisted ventilation, maintenance of blood pressure, etc., are essential.

Severe convulsions may be treated cautiously with thiopentone or a short-acting neuromuscular blocking agent such as suxamethonium chloride.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Marcain Plain 0.25%, Marcain Plain 0.5% and Marcain Plain 0.75% are each available in ampoules of 10 ml in boxes of 10 ampoules.

Further information Investigations in animals and man show Marcain in clinically used concentrations to be exceptionally well tolerated by all tissues with which it comes in contact. Electroneurographic studies after ulnar nerve blockade in volunteers indicate Marcain to have, if anything, less after-effect on both motor and sensory functions than equipotent concentrations of lignocaine and mepivacaine.

Product licence numbers

Marcain Plain 0.25% 0021/5020
Marcain Plain 0.5% 0021/5021
Marcain Plain 0.75% 0021/0108

MARCAIN* WITH ADRENALINE

Presentation Marcain with Adrenaline is Bupivacaine and Adrenaline Injection BP and is a clear, colourless, aqueous sterile solution in two strengths:

Marcain 0.25% with Adrenaline 1 in 400,000, containing:

Bupivacaine Hydrochloride BP 0.25% w/v
Adrenaline BP 1 in 400,000

Marcain 0.5% with Adrenaline 1 in 200,000, containing:

Bupivacaine Hydrochloride BP 0.5% w/v
Adrenaline BP 1 in 200,000

Uses The principal action of Marcain is to inhibit impulse transmission in nerve fibres with which it comes in contact. In a mixed nerve, sensory fibres are blocked before motor fibres, and among the different types of sensory fibres, those carrying the sensation of pain are affected before those carrying sensations of cold, heat, touch and deep pressure.

The local analgesic effect of Marcain is similar in rate of onset and depth to that of lignocaine and mepivacaine, but is of much greater duration; clinical evidence indicates that the quality of sensory blockade and interference with motor function provided by Marcain compares favourably with alternative agents. The addition of adrenaline in low concentration has been shown to increase both the speed of onset and the duration of analgesia. Marcain is approximately four times as potent as lignocaine or mepivacaine; hence a 0.5% solution of Marcain is equivalent in nerve-blocking activity to a 2% solution of lignocaine. Marcain is indicated primarily for specialist use in situations where prolonged analgesia is required. A list of suggested indications and the dose of solution appropriate for each are shown in the table below.

Marcain with Adrenaline				
Surgical procedure		Concentration (%)	Dose	
			(ml)	(mg)
Brachial plexus (axillary) block	0.25	20-40	50-100	
	0.5	15-30	75-150	
Lumbar extradural block	0.25	15-20	37.5-50	
	0.5	15-20	75-100	
Caudal extradural block	0.25	15-40	37.5-100	
	0.5	15-25	75-125	
Continuous extradural analgesia	0.25	The dose depends on the number of segments to be rendered analgesic and the patient's age (1-3 ml per segment)		
	0.5			
Intercostal block	0.25	4-8	10-20	
	0.5	3-5	15-25	
		for each nerve		
Stellate ganglion block	0.25	10-20	25-50	
Lumbar sympathetic block	0.25	10-20	25-50	
Herniorrhaphy	0.25	30-60	75-150	
Obstetrical procedure				
Lumbar extradural block	1st stage	0.25	6-15	15-37.5
		depending on site of catheter tip		
	2nd stage	0.25	12-20	30-50
0.5		8-14	40-70	
Caudal extradural block (intermittent)	1st stage	0.25	15-30	37.5-75
		2nd stage	0.25	15-30
	0.5		10-20	50-100
Bilateral pudendal block	0.25	50-60	125-150	

Dosage The maximum recommended dose of Marcain in any four-hour period is 2 mg/kg, representing 25–30 ml of 0.5% solution for a 65–70 kg adult.

For herniorrhaphy Marcain 0.25% with adrenaline 1 in 400,000 is used. Usually 30 to 40 ml is sufficient for the operation; up to 60 ml may be used but the dosage should not exceed 2 mg/kg. Some operators prefer to use Marcain Plain as this aids identification of the bleeding points.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity. Solutions of Marcain with Adrenaline should not be used in digital block or for intravenous regional analgesia because of the adrenaline content; Marcain Plain solutions should be used for these purposes.

Precautions: As with all local analgesic solutions, every care must be taken to avoid intravascular injection.

Side-effects: Hypotension after extradural or autonomic block may occur commensurate with such procedures. Other side-effects include tremor, tachycardia, bradycardia, malaise, vomiting, similar to other local analgesics.

Overdosage: The occurrence of adverse effects is related directly to the concentration of the drug in the blood, which in turn depends on the dose and the site of administration. Supportive measures to maintain vital functions such as maintenance of the airway, oxygenation with or without assisted ventilation, maintenance of blood pressure, etc. are essential.

Severe convulsions may be treated cautiously with thiopentone or a short-acting neuromuscular blocking agent such as suxamethonium chloride.

Pharmaceutical precautions Store in a cool place. Avoid freezing. Protect from light.

Legal category POM.

Package quantities Marcain 0.25% with Adrenaline 1 in 400,000 and Marcain 0.5% with Adrenaline 1 in 200,000 are each available in ampoules of 10 ml in boxes of 10 ampoules.

Further information Investigations in animals and man show Marcain in clinically used concentrations to be exceptionally well tolerated by all tissues with which it comes into contact. Electroneurographic studies after ulnar nerve blockade in volunteers indicate Marcain to have, if anything, less after-effect on both motor and sensory functions than equipotent concentrations of ignocaine and mepivacaine.

WAREVAN* TABLETS

Presentation Marevan Tablets are Warfarin Tablets BP.

Marevan Tablets 1 mg: Brown tablets engraved DF/M1, each tablet containing Warfarin Sodium BP 1 mg.

Marevan Tablets 3 mg: Blue tablets engraved DF/M3, each tablet containing Warfarin Sodium BP 3 mg.

Marevan Tablets 5 mg: Pink tablets engraved DF/M5, each tablet containing Warfarin Sodium BP 5 mg.

Jses Marevan is a synthetic anticoagulant of the coumarin series and acts by inhibiting the formation of

certain clotting factors. An effect on prothrombin time is produced in 24–36 hours after the initial dose. This reaches a maximum in 36–48 hours and is maintained for 48 hours or more after administration is stopped.

Coronary occlusion; deep vein thrombosis; pulmonary embolism; peripheral vascular thromboembolic states; mesenteric and retinal thromboembolism.

In emergencies, such as the conditions listed above, anticoagulant therapy should be initiated with heparin and Marevan together. Where there is less urgency, as in patients disposed to or at special risk of thromboembolism, anticoagulant therapy may be initiated with Marevan alone. Appropriate indications include predisposition to thromboembolism following surgery, during pregnancy and the puerperium and chronic embolic pulmonary hypertensive disease.

Dosage and administration 10–15 mg daily, according to age and body weight, and adjusted with relation to the results of daily control tests until the desired level of anticoagulant activity is achieved – usually three to six days after the initiation of treatment.

Concomitant heparin therapy affects the results of control tests and should be discontinued at least six hours before the first test is carried out.

Control tests should be made at regular intervals and Marevan maintenance dosage further adjusted according to the results obtained.

Contra-indications, warnings, etc

Contra-indications: Marevan should not be given in the presence of severe hepatic or renal disease, actual or potential haemorrhagic conditions, or to patients with uncontrolled hypertension. Its use within 24 hours following surgery or labour should be undertaken with caution if at all.

Precautions: The following factors may exaggerate the effects of Marevan and necessitate a reduction in dosage: loss of weight; elderly patient; acute illness; deficient renal function; decreased dietary intake of vitamin K; administration of a number of drugs, including salicylates, indomethacin, cimetidine, azapropazone, quinidine, broad spectrum antibiotics, phenformin, tolbutamide, phenylbutazone, clofibrate, ACTH and corticosteroids and all potentially hepatotoxic drugs. Factors which may call for an increase in maintenance dosage include weight gain, gastro-intestinal upset, increased intake of vitamin K, fats and oils, and administration of drugs (e.g. phenobarbitone) that increase liver enzyme activity.

Oral anticoagulants should not be used in pregnancy unless there are firm indications. In particular, because of possible teratogenicity, they should not be used for the remainder of the first trimester following diagnosis. In addition the risk of foetal haemorrhage is increased when they are used near term. It is therefore suggested that heparin (which does not cross the placenta) be used during the first trimester and after 37 weeks' gestation. However, the use of heparin in pregnancy is not absolutely safe and specialist guidance is advisable for those who are pregnant and who need anticoagulant therapy. Women of child-bearing age who are receiving treatment with Marevan should be cautioned about the possible complications of pregnancy.

Side-effects: Side-effects from Marevan are uncommon. A few instances of alopecia, skin rashes of various kinds, diarrhoea and an unexplained drop in haematocrit have been reported, and a 'purple toes' syndrome has been described. If any of these are observed administration of

Marevan should cease and a change be made to another anticoagulant. It may be advisable to avoid other coumarin preparations when a suitable alternative could be Dindevan*.

Skin necrosis within a few days of starting treatment has been infrequently reported. Most subjects are obese, elderly women. The first sign is an erythematous swollen patch. Administration of vitamin K₁ at this stage may prevent the development of ecchymosis and infarction.

Possible sensitivity to other drugs used should be considered. Bleeding due to anticoagulant overdosage is uncommon and unlikely to occur if the recommended method and degree of control is practised and the patient is maintained stable within the therapeutic range. An episode of bleeding occurring during anticoagulant therapy must, therefore, be investigated fully and not regarded simply as a manifestation of overdosage.

Overdosage: If haemorrhage occurs or a potential bleeding state arises, excessive depression of the coagulation activity can be corrected by temporary withdrawal of Marevan accompanied, if necessary, by administration of vitamin K₁ in oral doses of 2–20 mg; rarely it may be necessary to give vitamin K₁ intravenously, or to infuse fresh whole blood.

Pharmaceutical precautions Replace cap securely and protect from light.

Legal category POM.

Package quantities Marevan Tablets 1 mg are available in containers of 100 and 500.

Marevan Tablets 3 mg are available in containers of 100 and 500.

Marevan Tablets 5 mg are available in containers of 100 and 500.

MEVILIN[®]-L

Measles Vaccine (Live Attenuated) BP (Schwarz strain) Meas/Vac (Live)

Presentation Mevilin-L is a freeze-dried preparation of living attenuated virus of the Schwarz strain. It must be reconstituted with Water for Injections BP immediately prior to injection; the reconstituted vaccine may vary in colour from pale straw to pink – this variation is not indicative of deterioration.

Uses General prophylaxis against measles and within 3 days of exposure to measles.

Dosage and administration One dose by intramuscular or subcutaneous injection (contains not less than 1,000 TCID₅₀ of measles virus). Mevilin-L should be administered to infants at about 12 months of age. There is no upper age limit for measles vaccination.

To reconstitute Mevilin-L inject the required amount of Water for Injections BP (0.5 ml for the single-dose vial) into the vial containing the freeze-dried vaccine, allow to stand for about a minute then mix the suspension by withdrawing it into the syringe and expelling it back into the vial. The use of a 2 ml disposable syringe is recommended. The dose of the reconstituted vaccine is 0.5 ml.

Contra-indications, warnings, etc

Contra-indications: Mevilin-L should not be given to children below the age of one year unless at special risk. If this is the case, a second dose should be given at a later date as interference from maternally derived antibody may cause a failure to respond.

Any active or suspected infection is reason for delaying vaccination.

Mevilin-L should not be given to children suffering from leukaemia, Hodgkin's disease or other malignant conditions or hypogammaglobulinaemia. Also those with impaired immune responsiveness, whether occurring naturally or as a result of treatment with steroids, radiotherapy, cytotoxic drugs or other agents.

Pregnancy is a contra-indication. Also hypersensitivity to hen's egg, neomycin and polymyxin.

Children with the following conditions should not be given measles vaccine, unless with the simultaneous administration of normal immunoglobulin (0.6 mg/lb (1.3 mg/kg) body weight)† with a specific content of measles antibody:

1. History of convulsions.
2. Parental history of epilepsy (non traumatic).
3. Chronic disease of the heart or lungs.
4. Seriously underdeveloped.

If there is a history of convulsions or a history or family history of epilepsy, consideration should be given to delaying immunisation until after the second birthday.

Human Normal Immunoglobulin with a specific content of measles antibody is used to reduce the potential for adverse reactions where constitutional disturbance may be avoided in administering measles vaccine. A separate syringe should be used for injecting the immunoglobulin into the contralateral arm. It is important not to exceed the dose as overdosage can prevent the development of immunity.

Precautions: Attenuated measles vaccine is quickly killed by ether, alcohol and detergents: these agents should not be used for sterilising syringes prior to immunisation. Liquids used for cleansing the skin prior to injection should be allowed to dry before the vaccine is given.

Warnings: A sterile syringe and Adrenaline Injection BP should be ready for use, in case the need arises for emergency treatment of an allergic reaction.

Mevilin-L must not be given intravenously and should not normally be given within 3 months of a transfusion of blood or human plasma or treatment with Human Immunoglobulin except as previously specified. If any of these substances have been used near to the time of vaccination a test for the presence of measles antibody should be made at a later date.

The vaccine should not normally be given less than 2 weeks before or after immunisation with other live virus vaccines.

Measles vaccine may depress tuberculin skin sensitivity for 4 weeks or longer.

Adverse effects: When adverse reactions occur they

† Human Normal Immunoglobulin for use with Measles Vaccine is issued in ampoules, each containing 4–8 i.u. measles antibody in 15 mg protein in 0.5 ml solution. (See CMO letter CMO 5/68, CMO 18/71 and CMO (77) 3.) Supplies are available from Area Health Authorities in England and from Blood Transfusion Centres in Scotland.

usually appear about the eighth day. The symptoms are usually mild and may include malaise, cough, coryza, rash, pharyngitis, pyrexia and headache. Convulsions may accompany the fever.

Severe reactions are uncommon, but encephalitis has been reported – the incidence is considered to be approximately 1 in 1,000,000 vaccinees.

Pharmaceutical precautions Mevlin-L should be protected from light and stored in a refrigerator at between 2°C and 8°C (36°F to 46°F). Do not freeze.

The reconstituted vaccine should be used as soon as possible and certainly within one hour.

Neomycin and polymyxin are used in the tissue culture medium employed during manufacture and traces of these antibiotics may be present in the final vaccine.

Legal category POM.

Package quantities Single dose vial with 0.5 ml ampoule of Water for Injections BP.

Further information It is important to recognise that children in residential or day care over the age of one year are at special risk.

Product licence number 0021/0059.

MULTIVITE* PELLETS

Presentation A dark brown, sugar-coated pellet. Each Multivite Pellet contains:

Vitamin A	2,500 i.u.
Vitamin B ₁	0.5 mg
Vitamin C	12.5 mg
Vitamin D	250 i.u.

Uses Vitamins A, B₁, C and D are essential to health and vitality. Although these vitamins occur naturally in various foods, adequate nutrition is not always attainable or all. Even if balanced diets are achieved the vitamin content may be reduced or even completely destroyed by cooking. Patients with diminished appetites, restricted diets or inadequate meals, especially during childhood, pregnancy, illness and old age, often develop vitamin deficiencies. Multivite will help to correct a vitamin deficiency, and to build resistance against infection.

Dosage and administration *Adults:* 2 Multivite daily.

Children: 1 Multivite daily.

Multivite Pellets are pleasant tasting and may be chewed or swallowed whole, according to preference.

Contra-indications, warnings, etc There are no contra-indications.

Precautions: Excessive prolonged dosage of vitamins A and D may lead to hypervitaminosis.

Side-effects: None in the absence of overdosage.

Overdosage: No emergency treatment is necessary.

Pharmaceutical precautions To be stored in a cool place and protected from light.

Legal category P.

Package quantities Multivite Pellets are available in containers of 50, 150 and 500.

Further information Nil.

Product licence number 0021/5081.

NEO-NACLEX*

Presentation Small white tablets engraved Neo-NaClex on one side and scored on the reverse. Each tablet contains 5 mg bendroflumazide and complies with the specification for Bendroflumazide Tablets BP, BNF.

Uses *Oedema:* Neo-NaClex inhibits the renal tubular absorption of salt and water. Sodium and chloride ions are excreted in equivalent proportions, and there is little or no disturbance of the acid/base equilibrium. There is no important effect upon carbonic anhydrase. Neo-NaClex causes a steady diuresis lasting for about 12 hours. It is indicated in the treatment of oedema associated with conditions such as: congestive heart failure, nephrotic syndrome, cirrhosis of the liver, and pre-menstrual tension.

Suppression of unwanted lactation: Neo-NaClex can inhibit lactation as effectively as the oestrogens, but without early engorgement of the breast or other hormonal effects.

Essential hypertension: The mechanism whereby the thiazides exert their antihypertensive effect has not been clearly established. In non-oedematous patients there may be little noticeable diuretic effect. Neo-NaClex may be used as the sole antihypertensive agent, or as an adjunct to other drugs whose action it potentiates.

Dosage and administration *Oedema:* In adults 5 mg given orally once daily in the morning usually produces the desired effect, but this dose can be increased to 10 mg if required. During the first few days of treatment there is usually a large increase in urinary volume, which diminishes as treatment continues.

Maintenance: many patients will respond adequately to a daily dose of 2.5 mg or 5 mg on only two or three days in the week: sometimes a single dose once a week may be sufficient. The intervals allow opportunity for replenishment of any potassium loss. Appropriately smaller doses should be used for children.

Essential hypertension: 2.5–10 mg once daily, alone or in conjunction with other antihypertensive agents.

Pre-menstrual tension: 2.5 mg taken each morning for seven days before the period is due is usually adequate.

Suppression of lactation: A suitable dosage is 5 mg (or 10 mg) on rising in the morning and 5 mg about noon. A course of five days' treatment is usually adequate.

Contra-indications, warnings, etc

Contra-indications: Severe renal insufficiency, hypercalcaemia. Neo-NaClex should not be administered concurrently with lithium carbonate.

Precautions: Neo-NaClex may impair control of diabetes in patients receiving sulphonylureas.

Thiazide diuretics are secreted in mothers' milk, hence breast feeding should be avoided.

When treatment with Neo-NaClex is intensive or continuous, some loss of potassium may occur, and in these circumstances potassium chloride supplements are recommended. If the patient is vomiting, has diarrhoea or is suffering from an acute febrile or chronic illness (especially cirrhosis of the liver or heart failure) supplementary potassium may be particularly important. Supplementary potassium is strongly recommended if patients receiving digitalis require prolonged diuretic treatment. Concurrent therapy with carbenoxolone may also necessitate potassium supplements.

Potassium depletion may cause polyuria, malaise, muscle weakness or cramp, decreased tendon reflexes,

anorexia, dizziness, nausea or vomiting. Also, sensitivity to digitalis may increase and signs of over-dosage appear. Prolonged potassium deficiency may induce chronic pyelonephritis. Potassium supplements should not be given in renal insufficiency complicated by hyperkalaemia.

Side-effects: Impotence may occur and is usually reversible within a few weeks of stopping Neo-NaClex therapy. Mild anorexia or indigestion may occur occasionally, but it can be avoided or reduced by taking the dose during or immediately after a meal.

Skin reactions have been reported in a few patients and blood dyscrasias have occurred rarely. Expectant mothers who receive thiazide diuretics may be at increased risk from acute haemorrhagic pancreatitis; thrombocytopenia has been reported in newborn infants following antepartum use of thiazides. Such cases are very rare, and should not prevent the use of thiazide diuretics when indicated in pregnancy. Thiazides may aggravate existing diabetes mellitus, and cause symptoms in patients with latent disease. Serum uric acid levels may be raised, with or without gout, in some patients.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

Product licence number 0021/5906.

NEO-NACLEX[®]-K

Presentation Neo-NaClex-K is a film-coated, two-layer tablet containing bendrofluzide in the white layer and potassium chloride in the pink layer. The white side is engraved Neo-NaClex-K. The potassium chloride is in a special matrix which provides gradual release of the electrolytes, so minimising gastro-intestinal irritation. Each tablet contains 2.5 mg bendrofluzide and 630 mg potassium chloride, providing 330 mg elemental potassium (8.4 mEq).

Uses *Essential hypertension:* The mechanism whereby the thiazides exert their antihypertensive effect has not been clearly established. In non-oedematous patients there may be little noticeable diuretic effect. Neo-NaClex-K may be used as the sole antihypertensive agent, or as an adjunct to other drugs whose action it potentiates. When Neo-NaClex-K is used alone in hypertension, the fall in diastolic blood pressure is often between 10 and 20 mm Hg.

When Neo-NaClex-K is added to other antihypertensive drugs, the dosage of the latter can usually be reduced gradually as the Neo-NaClex-K takes effect.

The potassium chloride contained in Neo-NaClex-K provides a useful supplement to offset the potassium-losing effect of bendrofluzide.

Oedema: Neo-NaClex-K is particularly suitable for the treatment of chronic oedema.

Dosage and administration *Essential hypertension: Adults:* 1-4 tablets once daily, alone or in conjunction with other antihypertensive agents.

Oedema: *In adults:* 2 tablets given orally once daily in the morning usually produce the desired effect, but this dose can be increased to 4 tablets if required. During the

first few days of treatment there is usually a large increase in urinary volume, which diminishes as treatment continues.

Maintenance: Many patients will respond adequately to a daily dose of 1 or 2 tablets on only two or three days in the week, sometimes a single dose once a week may be sufficient.

Appropriately smaller doses should be used for oedema in children.

Contra-indications, warnings, etc

Contra-indications: Gross impairment of renal function hypercalcaemia. Neo-NaClex-K should not be administered concurrently with lithium carbonate.

Precautions: Thiazide diuretics are secreted in mother's milk, hence breast feeding should be avoided.

When treatment is prolonged and intensive, potassium depletion can develop insidiously particularly in the presence of diarrhoea or vomiting. Neo-NaClex-K Tablets usually provide sufficient potassium to maintain the serum concentration in hypertension, but in oedema it is sometimes advisable to give potassium chloride in addition to that contained in Neo-NaClex-K. Potassium deficiency increases the activity of digitalis and signs of overdosage may appear.

Neo-NaClex-K may impair control of diabetes in patients receiving sulphonylureas.

Side-effects: Impotence may occur and is usually reversible within a few weeks of stopping Neo-NaClex-K therapy. Mild anorexia or indigestion may occur occasionally, but it can be avoided or reduced by taking the dose during or immediately after a meal. If abdominal pain, distension, nausea, vomiting or gastro-intestinal bleeding occur during the administration of tablets containing potassium salts, administration should be discontinued immediately. Small bowel lesions are usually associated with enteric-coated tablets, and are less likely to occur with Neo-NaClex-K.

Skin reactions have been reported in a few patients and blood dyscrasias have occurred rarely. Expectant mothers who receive thiazide diuretics may be at increased risk from acute haemorrhagic pancreatitis; thrombocytopenia has been reported in newborn infants following ante-partum use of thiazides. Such cases are very rare and should not prevent the use of thiazide diuretics when indicated in pregnancy. Thiazides may aggravate existing diabetes mellitus, and cause symptoms in patients with latent disease. Serum uric acid levels may be raised, with or without gout, in some patients.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

Product licence number 0021/5907.

ONADOX[®]-118 TABLETS

Presentation Soluble white tablets engraved DF/C each tablet containing:

Acetylsalicylic Acid BP (as soluble salt)	300 mg
Dihydrocodeine Tartrate BP	10 mg

Uses Aspirin in soluble form as calcium aspirin has been shown to reduce the risk of gastric intolerance and bleeding. Dihydrocodeine tartrate has been widely used

for a number of years as a powerful analgesic: 30 mg of dihydrocodeine has been reported to have analgesic potency equal to 60–120 mg codeine. In addition the compound exhibits well-defined anti-tussive activity.

There is evidence that aspirin and centrally acting analgesics (such as dihydrocodeine) probably act by different mechanisms, and their actions should, therefore, complement each other. Onadox-118 thus provides an effective combination of drugs for the long-term treatment of rheumatic conditions, where adequate relief of pain is not obtained with aspirin alone, and, more generally, where relief of mild to moderate pain is required.

Dosage and administration Onadox-118 should be dissolved in water and taken during or after a meal.

Adults: 1–3 tablets, three or four times a day, as required. Onadox-118 Tablets are not recommended for administration to children.

Contra-indications, warnings, etc

Contra-indications: Onadox-118 should not be administered to patients with peptic ulceration, respiratory depression, obstructive airways disease, haemophilia or a sensitivity to aspirin; nor should it be prescribed concurrently with oral anticoagulants.

Precautions: Additive CNS depression may occur with alcohol.

Onadox-118 should be given with caution to patients with allergic disorders and should not be given during an attack of asthma.

Dosage should be reduced in the elderly, in hypothyroidism and in chronic hepatic disease.

Aspirin may induce asthma, precipitate bronchospasm and inhibit action of uricosurics. There is no, or inadequate evidence of safety in human pregnancy but the drug has been used for many years without apparent ill consequence. It may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term.

Side-effects: Constipation, if it occurs, is readily treated with a mild laxative. Nausea, headache, vertigo and gastro-intestinal haemorrhage, occasionally major, may occur in a few patients.

Overdosage: Gastric aspiration, lavage and general supportive measures should be carried out. Severe respiratory depression can be treated with naloxone hydrochloride 0.4 mg subcutaneously, repeated as required at 2 or 3 minute intervals.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Onadox-118 Tablets are available in cartons of 100, strip packed in protective foil.

Further information Nil.

Product licence number 0021/5055R.

PARAMOL*-118 TABLETS

Presentation A white tablet engraved DF/P, each tablet containing:

Paracetamol BP	500 mg
Dihydrocodeine Tartrate BP	10 mg

Uses Paracetamol is an effective analgesic possessing a remarkably low level of side-effects. Its broad clinical utility has been extensively reported, and it now largely

replaces aspirin for routine use. Paracetamol is well tolerated; having a bland effect on gastric mucosa, unlike aspirin, it neither exacerbates symptoms of peptic ulcer nor precipitates bleeding. Dihydrocodeine tartrate has been widely used for a number of years as a powerful analgesic; 30 mg of dihydrocodeine has been reported to have analgesic potency equal to 60–120 mg codeine.

In addition the compound exhibits well-defined anti-tussive activity.

By fortifying paracetamol with 10 mg dihydrocodeine, Paramol-118 provides an effective combination of drugs for the treatment of mild to moderate pain and as an anti-pyretic.

Dosage and administration Paramol-118 Tablets should, if possible, be taken during or after meals.

Adults and children over 12 years: Analgesia: 1 tablet every four hours. This may be increased to 2 tablets four times a day if necessary.

Antitussive: 1 tablet every four hours.

Paramol-118 is not recommended for children under 12.

Contra-indications, warnings, etc Respiratory depression, obstructive airways disease.

Precautions: Additive CNS depression may occur with alcohol.

Paramol-118 should be given with caution to patients with allergic disorders and should not be given during an attack of asthma. Caution should also be observed if there is marked impairment of liver function or advanced kidney disease.

Dosage should be reduced in the elderly, in hypothyroidism and in chronic hepatic disease. An overdose can cause hepatic necrosis.

There is no, or inadequate evidence of safety in human pregnancy but the drug has been used for many years without apparent ill consequence.

Side-effects: Constipation, if it occurs, is readily treated with a mild laxative. Nausea, headache, vertigo and giddiness may occur in a few patients.

Overdosage: Conservative management is recommended; gastric lavage should be carried out. Severe respiratory depression can be treated with naloxone hydrochloride 0.4 mg subcutaneously, repeated as required at 2 or 3 minute intervals. Treatment for paracetamol overdosage should be commenced as soon as possible after ingestion using preferably N-acetylcysteine or cysteamine or methionine.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Paramol-118 Tablets are available in packs of 100 and 500.

Further information Nil.

Product licence number 0021/5056.

PARVOLEX* ▼

Presentation Parvolex is a clear, colourless, sterile, pyrogen-free, aqueous solution of 20% w/v N-acetylcysteine (N-acetyl-3-mercaptoproline) adjusted to pH 7.0 with sodium hydroxide. Parvolex contains 200 mg N-acetylcysteine in each ml.

Uses N-acetylcysteine is a derivative of the naturally-occurring amino acid L-cysteine.

In paracetamol overdosage the observed hepatotoxicity is due to the formation of a toxic metabolite which is thought to cause liver cell damage and necrosis. Hepatic-reduced glutathione inactivates the toxic metabolite by conjugation but glutathione stores are rapidly depleted with hepatotoxic doses of paracetamol. N-acetylcysteine, being a sulphhydryl (SH) group donor, protects the liver possibly by restoring depleted hepatic-reduced glutathione or by acting as an alternative substrate for the toxic paracetamol metabolite.

Indications: Paracetamol overdosage.
